Fig. 4. Specially-wound spark coils.

had to be adequately filtered before it could meet the prescribed specifications—especially if it was to be used for a near-pure CW purpose. Filters were needed to eliminate key clicks. With batteries, there was complete absence of blinking lights, buzzing, whining, vibrating generators, and many ac growls on the air.

Other Substitutes For B Supplies

A convenient and inexpensive unit known as the mercury arc rectifier, equipped with an electrolytic "keep-alive" mechanism, was extensively used to give up to 3000 volts of B supply power. Both voltage and current outputs satisfied a one-kilowatt transmitter (Fig. 2).

Also available was a synchronous rectifier, as shown in Fig. 3. A synchronous motor, 1800 rpm, carried a large-diameter split wheel, with which two husky commutator brushes made contact. In this way, the 60-cycle current was rectified and the pulsating directional output then filtered. These units were marketed under the name of Super-Sync and provided plate energy rated at up to 4,000 volts.

Some of the early plate supplies were obtained from specially-wound spark coils—see Fig. 4. Such transmitter assemblies put out an ICW signal, were extensively used, and solved the high-cost problem. It was necessary to adjust the vibrator frequently to obtain a smooth tone, the pitch being immaterial but often adjusted to satisfy the contacted operator at the other end.

Radio amateurs in the early 1920s were an experimental and ingenious lot. They solved their problems in the best amateur tradition. ■

Maximum Security for the 22S

—remote control puts your Icom in the trunk

Probably one of the most versatile and easily modified radios on the market today is the Icom 22S. A multitude of frequency combinations can be selected simply by soldering inexpensive diodes into one of the 22 matrix board divisions.

The purpose of this article is to look at a few easy and inexpensive modifications which can be done to allow either greater frequency selection flexibility or remote control of the Icom "Mobile Marvel."

Upon examining the Icom 22S, one of the first things one usually notices is that, although the radio is advertised as a 22-channel rig, the programming matrix board and selector switch have 23 positions. To initiate 23-channel operations, all one need do is connect a short piece of wire from switch lug 23 to the 23rd diode row and program the row with appropriate diodes for the extra frequency of your choice.

The second easy modification is the use of the 23rd position in conjunction with a few diodes and a DIP switch to allow the selection of any combination of available frequencies. Articles in the *73 Magazine* issues of June, 1977 (p. 152), and May, 1978 (p. 158), showed DIP switch mounting methods which required external components subject to easy breakage, or required defacing the cabinetry of the radio. An alternate method which allows easy DIP switch programming without defacing the exterior of the radio, while providing a secure and strong DIP switch mount, is shown in Fig. 1.

All one needs to do is simply (1) remove the 24-pin accessory plug from its holder, cover it with tape to prevent shorts, and push it inside the case, and (2) glue a section of perfboard on the accessory plug support bracket, mount your DIP switch on the perfboard, and wire as shown in Fig. 2. At this point, your 22-channel radio can be programmed for any of the frequencies listed in the owner's manual, without resoldering diodes.

The final modification I will describe was inspired as much by my laziness as by security needs. Often I find myself needing to stop in town for some small item. As in most urban areas, this requires that either you remove your radio from the car or trust fate that it will be there when you return.

Not being one who enjoys disconnecting my rig and placing it in the trunk four or five times a day, I conceived the idea of remote controlling the Icom and mounting it in the trunk.

To my great surprise, this modification is both easy

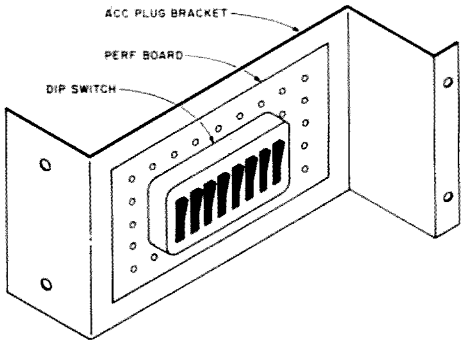

Fig. 1.

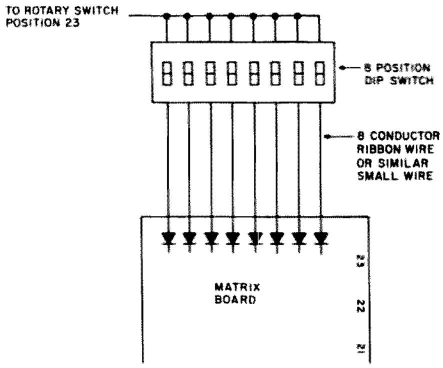

Fig. 2.

and inexpensive. All that is required is some wire, two potentiometers, two knobs, one male and female 4-pin mike jack, a speaker and miniature phone jack, a rotary switch, and a small box, such as the Radio Shack #270-236.

To accomplish remote frequency selection, run a wire from an unused channel position on the matrix board (Point A in Fig. 3) to the common of the remote 23-channel selector switch, via the accessory jack, as shown in Fig. 3. Note that the previously-mentioned DIP switch location cannot be used with remote control. It will be necessary to mount your DIP switch elsewhere (see Leon Baldwin's article in the May, 1978, issue of *73 Magazine*). Next, run your return leads from the rotary switch back to the matrix board via the accessory jack. All 22 previously-programmed channels cannot be remotely selected due to the use of the accessory jack to carry volume, squelch, and duplex controls.

If you do not have a 23-position rotary switch, an alternate method may be to use a double-ganged, 12-position rotary switch and toggle switch combination, as shown in Fig. 4.

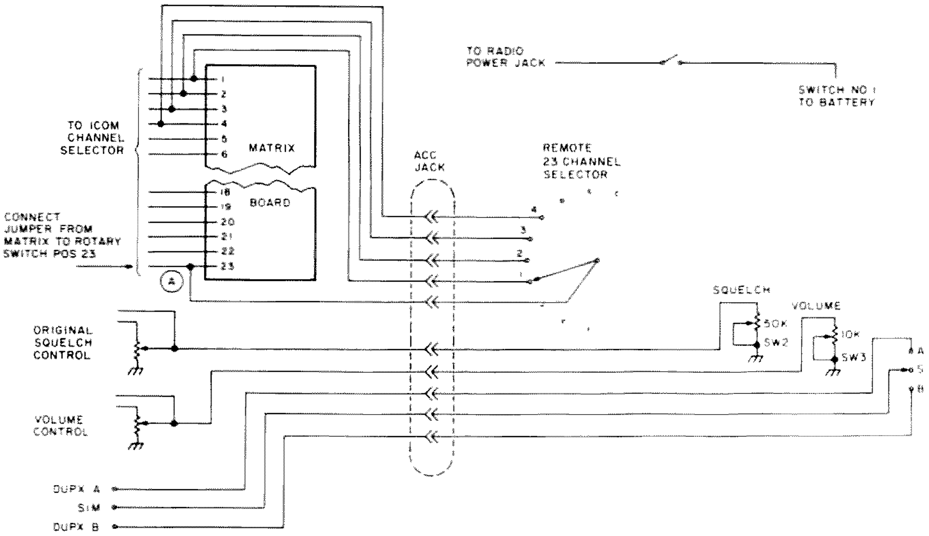

Fig. 3.

To vary the volume and squelch level, simply install a pot in parallel with the wiper on the original controls, as shown in Fig. 3. Slight problems may arise in the volume control circuit. Usually, this is due to a pot which will not adjust to a low enough value. It may be necessary to substitute a pot other than the one specified.

Duplex-simplex control also is accomplished as shown in Fig. 3. Power for the unit is delivered from switch 1 in the control panel.

To operate remote, install the unit with the power switch on the radio in either high or low position. Turn the squelch controls on the radio to maximum, and the volume to about mid-point. Place the channel selector in position 23, and control as usual from the remote unit.

I hope that this article will stimulate interest in Icom owners to build the remote unit, and possibly to try other remote control modifications to which this versatile little unit might well be suited.■

The Big Blinker

—a visual signal for the deaf

A friend recently asked me for something which could be used in conjunction with an alarm clock in order to awaken his deaf nephew in the morning. The circuit which I finally came up with is shown in Fig. 1.

Basically, it works as follows: The sound of the alarm is picked up by a crystal microphone element, amplified by U1A and U1B, and detected by the full-wave rectifier consisting of U1C and diodes D1 and D2. The rectified voltage is next applied to a comparator (U1D). When the input signal is loud enough and of a long enough duration, the rectified voltage on the inverting input of U1D exceeds the reference on the non-inverting input, causing the output of U1D to go to Vee. This turns on transistor Q1, which then enables U2, a 555 timer operating as a one-second oscillator. The output of the 555 drives a triac, which in turn causes a lamp plugged into the ac socket to flash at a one-second rate.

For best results, tape the microphone to the alarm clock and adjust the comparator threshold so that only the alarm clock sound triggers the unit. Transient noises will not enable the circuit due to the RC time-constant at the detector output.

All of the parts are readily available at your local Radio Shack. I used an LM324 quad op amp, but any quad, two dual, or four single op amps can be used. The pin numbers shown were for my particular layout but, of course, any of the op amps can be interchanged.

This unit performs quite well, and is certainly more of an attention-getter than the original timer used. The original timer was used to simply turn on a light. The triac used can handle up to 6 Amps, so several lamps can be plugged into the unit. The lamps will continue to flash as long as the alarm is sounding. ■

Morse Converter for DMMs

—super gadget for blind hams

A digital converter which will take the binary coded decimal (BCD) output of a digital multimeter (DMM) and convert it to Morse code would surely be an asset to any blind or partially blind person's workshop.

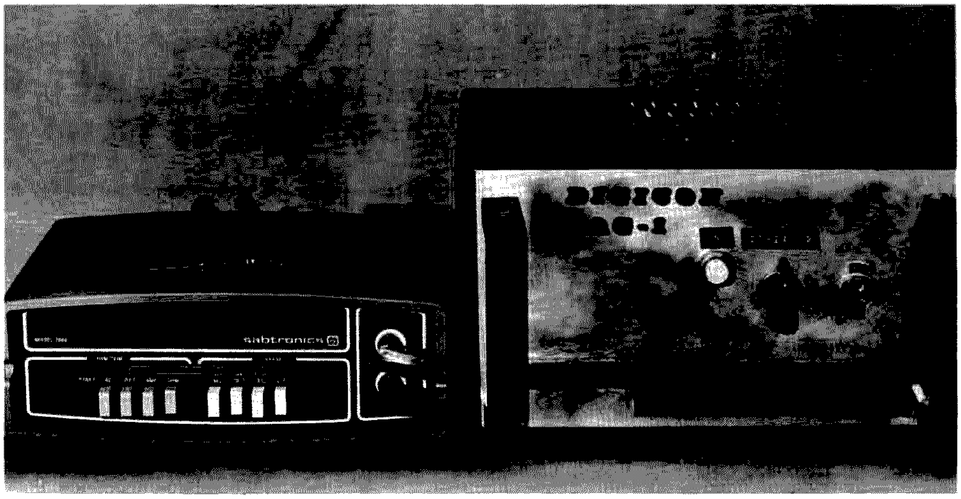
After graduating from a CREI home study course in electronics engineering technology (minicomputers and microprocessors as the major elective), I had a strong desire to make some practical use of the knowledge.

Shortly after finishing the home study course, I was talking with my dear friend of nine years, W6LZV. He was mentioning that a Morse clock could be helpful to him in his daily on-the-air operations. After thinking about a Morse clock versus another type of device which could be converted to a Morse code output, I asked Jean if he could use a digital multimeter with Morse code output. Though Jean is completely blind, he is very active in the building and repairing of electronic equipment. Therefore, it was no surprise to me when he said that the DMM-to-Morse code converter would be more functional.

This article is for the person who wants the challenge of using an instrument which was originally made for the sighted person. This article can open doors that have inhibited the handicapped person in delving into a world of technical discovery—a world which can be just as satisfying for him as for the sighted person.

While researching what chips might be commercially available to handle the BCD-to-Morse code conversion in a very simplified manner, I ran across the July, 1977, issue of *73 Magazine*, which has an article entitled "The Morse Clock." After reading and rereading the article, trying to fully understand the logic, I decided that I would use the article as a starting point for my design of the DMM-to-Morse code converter.

The digital multimeter used for this prototype project was the Sabtronics 2000 DMM. At first, I had only a schematic of the DMM to work from, but it was apparent that converting the output of the MC14433 A/D converter chip into Morse code would not be too difficult. After building the DMM and seeing how the MC14433 chip worked, I decided that since the position of the decimal point depends only upon the function button and range button selected and upon whether the X10 range switch is used, I would disregard the decimal point. Only the minus sign and the 3½ digits were dealt with.



The converter at work. The DMM indicates −108.5 Ohms. (The minus sign is peculiar to the Ohms reading on this DMM.) When the INI button is pushed, the converter will respond with — —(minus) · — — — — — — — — — — — — · · · · · · ·.

Features of the DMM-to-Morse Code Converter

The converter was designed to provide the following:

1. Morse code output of the 3½ digits.
2. Morse code character "m", which signifies that a minus sign is present.
3. An audible over-range indicator.
4. A method by which the user can perform "continuity tests."
5. Three selectable code speeds.
6. A Morse code zero (0) for a "blanked" first digit.

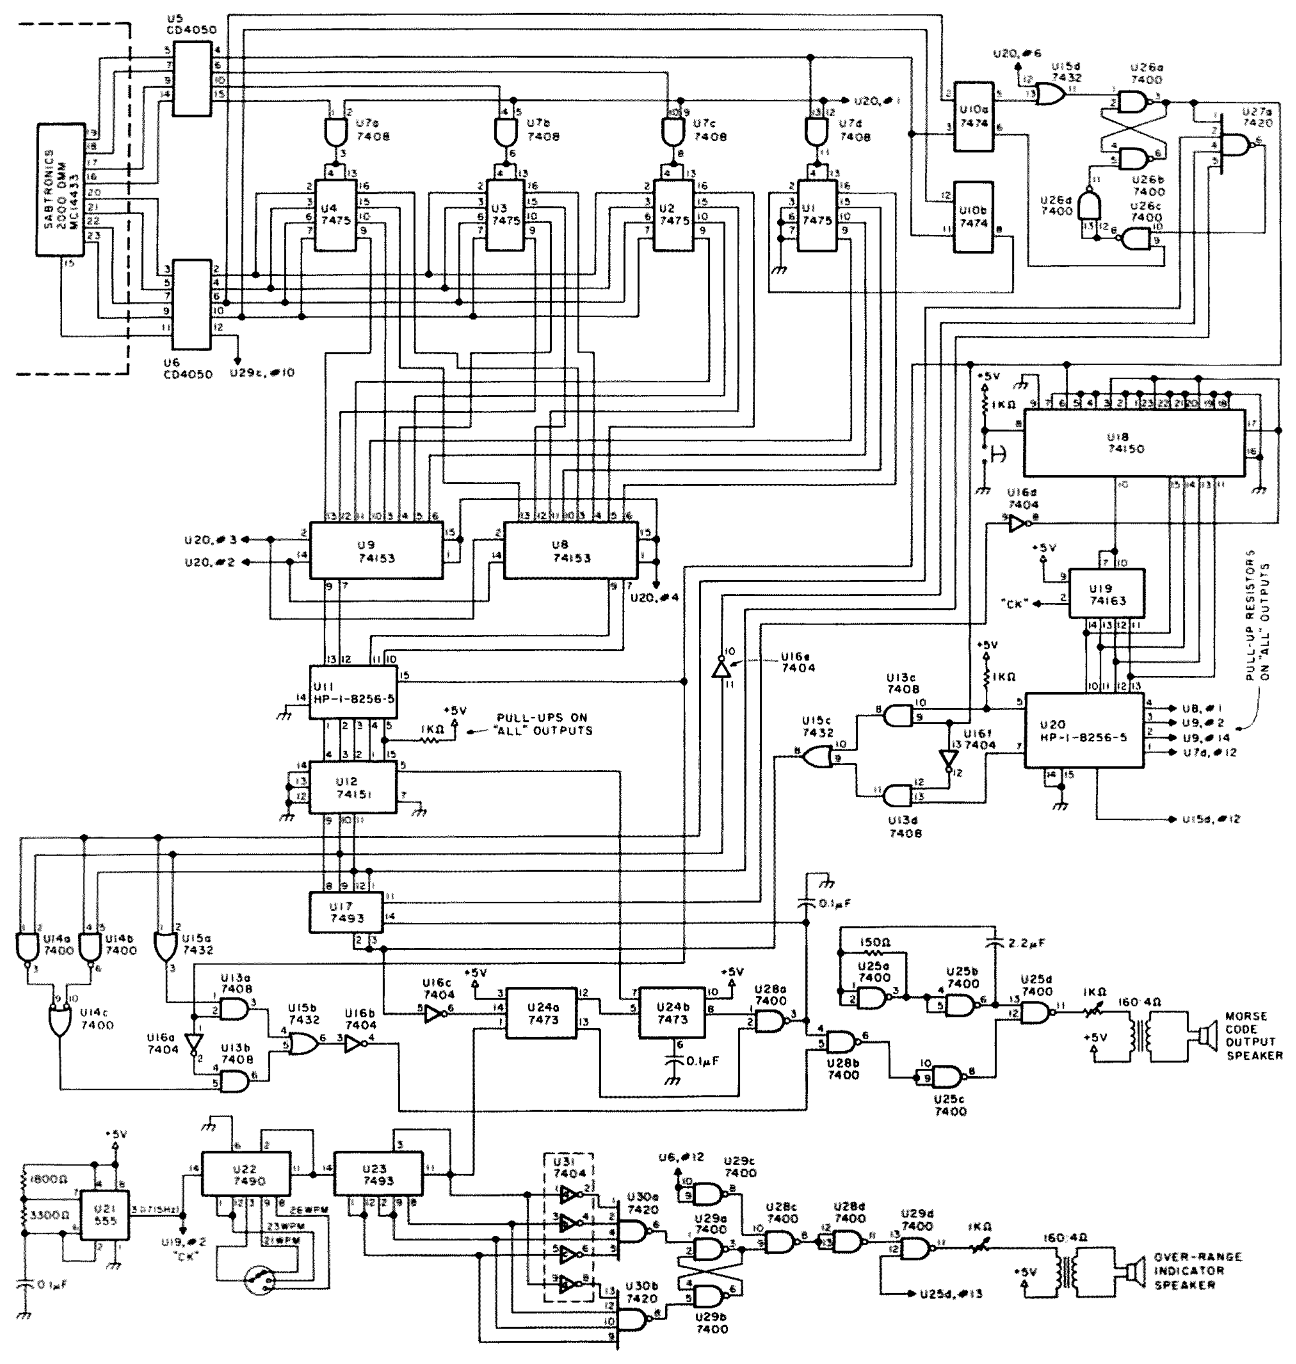


Fig. 1.

This was done because I am not audibly providing the position of the decimal point. By giving the user the contents of all 3½ digits, the mental determination of the decimal point's placement is made easier.

Circuit Description

The MC14433 A/D converter chip (enclosed in the DMM) is the heart of the converter. The chip has BCD outputs available for the 3½ digits, but they must be demultiplexed "off-chip" by using the display triggering lines. Since the demultiplexing and selection of each digit is not available "on-chip," the chip count of the DMM-to-Morse code converter is higher than for the Morse clock.

Since I have never tackled a complete project from the design stage to the building stage, various aspects of the MC14433 chip posed some minor stumbling blocks. After reading the article entitled "Super DVM" (August, 1977, issue of *73 Magazine*), I selected a single 7474 (dual D flip-flop) to demultiplex the ½ (first) digit and the minus sign. The 7474 chip solved the minor stumbling blocks.

The Minus Sign

The minus sign demultiplexing, sampling, storage, and recovery circuits are made up of U10A, U15D, U26A and B, U26C and D, and U27A (respectively).

When a minus sign is present, the 7400 SR flip-flop (U26A & B) provides the following actions: 1. Selects the appropriate

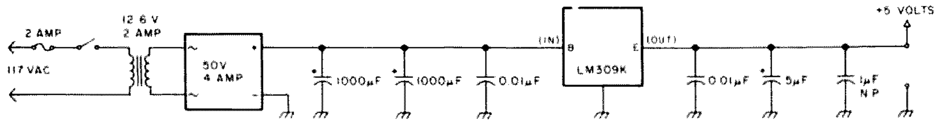

Fig. 2.

State	IRENABLE (+), U13D/pin 13	MINUS SAMPLING, U15D/pin 12	IRENABLE (−), U13C/pin 10	74153 (enable), U8/pin 1	74153 (B), U9/pin 2	74153 (A), U9/pin 14	DIGIT LOCK-UP, U7D/pin 12	Remarks
0000	X	X	X	X	O	O	X	Wait for "next instruction"
0001	X	O	X	X	O	O	O	Address (−) Minus sign

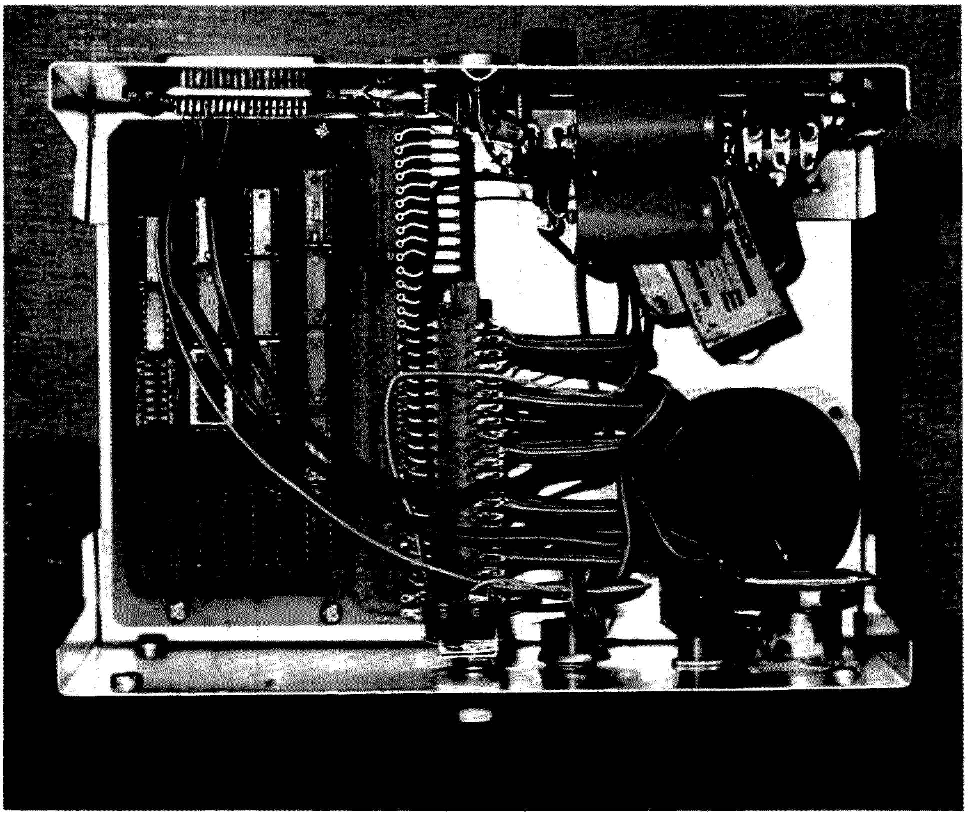
0111	X	X	X	O	O	X	O	Address 2nd digit
1000	O	X	O	O	O	X	O	Send 2nd digit
1001	X	X	X	X	X	O	O	Clear BCD-Morse code converter
1010	X	X	X	O	X	O	O	Address 3rd digit
1011	O	X	O	O	X	O	O	Send 3rd digit
1100	X	X	X	X	X	X	O	Clear BCD-Morse code converter
1101	X	X	X	O	X	X	O	Address 4th digit
1110	O	X	O	O	X	X	O	Send 4th digit
1111	X	X	X	X	O	O	O	Clear BCD-Morse code converter

Table 1. Contents of the "control" ROM (U20).



Top view of completed unit.

output line (IRENABLE−) from the state-machine ROM; 2. Selects the appropriate logic used for giving the "space" between the Morse code characters; 3. Disables the BCD-to-Morse code ROM. When this ROM is disabled, all of its outputs are driven HIGH, thus providing the needed output for making the Morse code character "m"; 4. Signals the input multiplexer (U18, 74150) that the "m" and the "space" between characters has been sent (no-code condition). Spacing between the Morse character "m" and the first digit is longer than between "each" digit. This characteristic provides a distinguishable pause between the "m" and the start of the first digit.

The First Digit

The ½ (first) digit demultiplex and storage circuitry is made up of U10B and U1 (respectively). Since the ½ digit is only a zero (0) or a one (1), I tied the binary 2, 4, and 8 inputs of U1 to ground (binary zero) and let the output of the 7474 dual D flip-flop (U10B) determine whether a zero or a one is showing in the ½ digit's place.

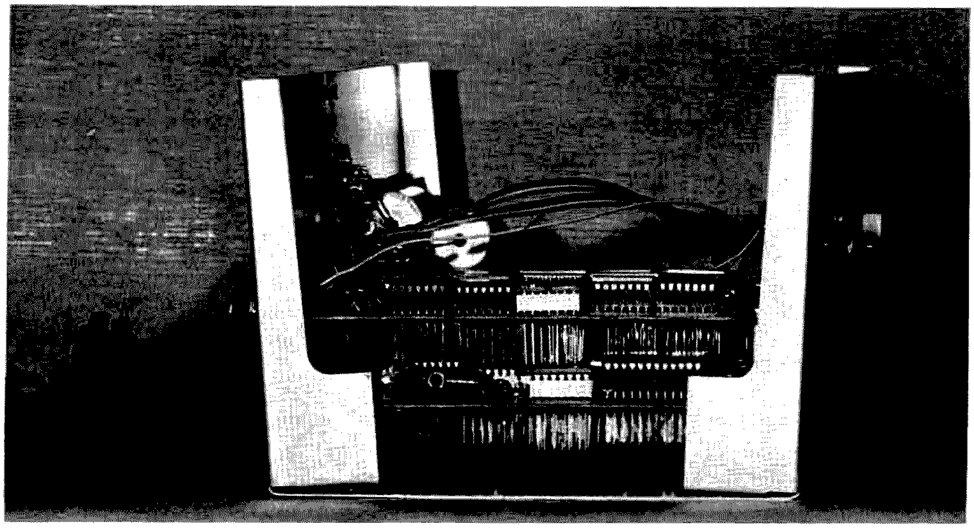
The Over-range Indicator

A 7493 counter (U23), wired as a divide-by-10 counter, is used to provide the counter-states which make up the "ditters" when an over-range condition exists. The 7493 counter-states of 2 and 7 are decoded and driven to a 7400 $\overline{SR}$ flip-flop, which provides the ditter sensation.

Besides providing the user with an indication of an over-range condition, the over-range indicator circuitry can also be used to provide a continuity test. When the DMM is placed in the OHM function and an OPEN condition exists between the input terminals, all digits are

blanked (to the sighted user) and the over-range ditters are HEARD. With this condition in mind, the user takes the test leads and makes the necessary connections for determining if there is an open or a shorted condition. After making the connections, if the ditters persist, an open condition exists (verified by pressing the "initiate" button and hearing "m" 1 9 9 9). If the ditters cease, the user either has a shorted condition or some actual value of resistance. A shorted condition can be verified by pressing the "initiate" button and hearing either "m" 0 0 0 0 or just 0 0 0 0.

When the function switch is in the OHM position, the user must ignore the "m" (minus sign) which is active due to the design of the DMM. During the OHM function, the minus sign shows up (for the sighted person) to tell the user that the input jack (positive jack) is in fact the negative probe, and that the DMM is in fact turned ON.



Side view of completed unit.

Construction/Miscellaneous Notes

Excluding the MC14433 in the DMM, the prototype project has a chip count of 31. All ICs used in the project were of the commonly-available type. All parts were either obtained locally or through various electronic parts catalogues.

I used the wire-wrap technique because it gave the amount of versatility in construction that I wanted. I was able to build each functional section bit-by-bit.

Interfacing of the CMOS 14433 with the TTL 7475 and 7408 was achieved by using two CD4050s (hex buffers).

I am sure that there are many alterations which can be made to my present design. These could include feeding the Morse code output and the over-range output through a "summing" op amp amplifier, thereby needing only one speaker. Also, U5 and U6 could be deleted if we dealt with CMOS technology throughout the converter.

The cost of the converter parts (including the cabinet and wire-wrap PC boards) was approximately $120.00, but the cost could be brought down easily to approximately $60.00 if the builder has a well-stocked junk/spare-parts box and if he shops around.

My sincere thanks to WB3EVS for his technical assistance, to WA6DLI for his superb photographic shots of the converter, and to WA1MXV and WA5VQK for their very enlightening articles. ■

How to Home-Brew Your Own Crystal Filters

— the series-string method

73 Magazine *Staff*

One of the prime limitations that discourages many amateurs from pursuing various interesting projects is the cost of good crystal filters. One example is with the construction of rf speech processors or clippers. Clippers are relatively easy to build and very effective, but they require the use of a good SSB filter.

One of the simplest forms yet of a good home brew crystal filter was recently discovered. Hopefully, it will allow many amateurs to pursue some of those projects they have been putting aside because of the expense of commercial filters.

The crystal filter to be described can be built around a group of almost any commonly available MHz-range crystals of the same frequency. The crystals which are manufactured for TV games or color TV sets are particularly suitable since they are manufactured to close tolerances and are inexpensive. For instance, the 3.579545 MHz crystals for color TV set circuits are readily available for only around $1.00 because they are mass produced in such quantities. In fact, with a bit of hunting through sales flyers, one often can find them on sale at 6 for $5.00.

As the title of this article implies, the circuit for the crystal filter is nothing more than a series-connection of the crystals, as shown in Fig. 1. The input and output of the filter are terminated by 1k-Ohm resistors. The trimmer capacitors are used to obtain the overall desired response. The type of response that can be obtained is shown in Fig. 2. The frequency scale has been expanded somewhat on the graph, so at first glance the filter response may seem rather broad. Actually, it is quite good if one studies the response in a bit more detail. The −60-dB bandwidth is about 8 kHz. The ultimate out-of-passband rejection could not be measured much beyond −60 dB with the equipment available, but the ultimate rejection is probably −80 dB or better. Just for comparison, the response of a medium-priced ($40 range) imported filter is shown by the dot-dash lines inside the series-string filter

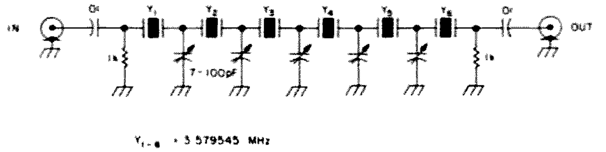

Fig. 1. The series-string crystal filter.

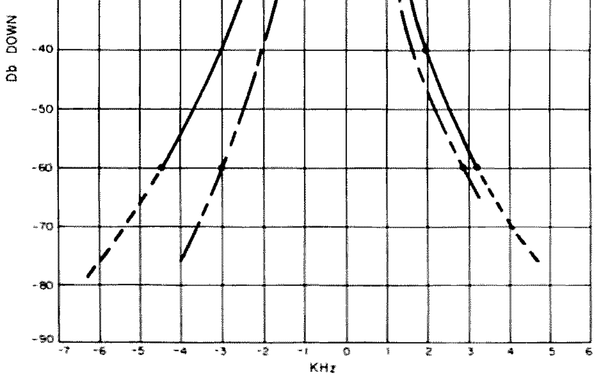

Fig. 2. Response of the series-string crystal filter (outer curve) compared to that of a moderately-priced commercial filter (inner curve).

response. The commercial filter is better, of course, and one will notice some difference on receiving, but it is a moot point as to whether any difference would be noticed when SSB filtering is considered for transmitting purposes or when rf speech processing equipment is being considered.

In order to achieve the response described, the filter must be constructed carefully, although this is not a tedious task. The filter is constructed basically as shown in Fig. 1, so the input-output terminals are as far apart as possible. Fig. 3 shows the layout used on an approximately 1½" x 5¼" piece of copperclad (single-side) PC board. There is no need to do any etching unless one just prefers to do this. The isolated-pad type of construction works very well, where a small hole is drilled for each crystal lead or pin (depending on the type of crystal used). The copper around the hole is removed for a small radius with an isolated-pad tool or with a sharp knife. The crystals are simply interconnected, and the few components required are soldered directly to the crystal leads or pins. The input-output cables are connected to any form of isolated terminal post. The trimmer capacitors used are Arco 423 units which have a range of 7-100 pF, but any similar units can be used. In fact, if one doesn't devote a little effort to finding reasonably-priced trimmer capacitors, they can cost more than the crystals!

The adjustment of the five trimmer capacitors will have a great deal of influence on the bandpass shape of the crystal filter. If one has fancy test gear available, such as spectrum display units, the work is, of course, relatively simple. But, even if one has only relatively simple test equipment—rf generator and a suitable oscilloscope or a receiver—the filter can be adjusted easily enough.

First, set up the filter so the middle trimmer-capacitor is at minimum value, and the other capacitors are at maximum value. Then, as one goes through the passband of the filter with the rf generator, note how the response changes as the center trimmer is increased in value and the other trimmers are decreased. If one keeps a record of the responses for each adjustment of the trimmers, it will not be difficult to discern the pattern that develops. No attempt was made to adjust the trimmers by ear when the filter was used in a receiver, but possibly, with enough patience, it could be done.

The application of the filter to a piece of equipment, or the use of the filter in an accessory item, can follow the scheme shown in Fig. 4. This little setup made use of various International Crystal Company modular mixer and oscillator units to translate the crystal filter response to another i-f frequency that was of interest. However, this setup, or one similar to it that is suitable for the frequencies involved, can be used for many applications.

For instance, one can use it just to improve the i-f selectivity in an older piece of equipment, or those who are a bit more advanced in circuit construction can build a complete outboard rf speech processor for an SSB transmitter, using two crystal filters. (See Fig. 5.) A DSB signal is first generated, and one filter used to produce an SSB signal. The signal is then clipped and passed through the second filter to clean up the distortion products. The product detector is used to obtain the final af signal. In this application, the two crystal fitlers should have identical passband responses—but this should not be difficult to achieve if they are constructed and adjusted together. During the adjustment process, one should note where the 20- to 30-dB down points are, on either the upper or lower side of the crystal filters, since either one of the two frequencies can be used as the carrier oscillator frequency.

Construction has been started on such a project, but it is not yet completed. Even using a modular approach as much as possible, by using kit-type modules of the kind shown in Fig. 4, the total cost for the project seems to be coming out in the $25-$30 range. That is not bad at all when one considers that it includes the cost of two crystal filters, and one can pick up several dB of extra intelligibility under QRM conditions. Even if one does not achieve the full theoretical improvement possible with rf clipping, one can easily do better than by using an outboard audio compression or clipping accessory, and at nearly the same cost.

It is possible to use the crystal filter also as part of an adapter to add rf clipping to an SSB transmitter, by connecting it into the SSB generation chain. Unfortunately, one cannot generalize on how this can be done, since the response of the filter in the outboard adapter as compared to the response of the filter in the transmitter, along with the carrier oscillator frequencies, all have to be taken into account for a specific transmitter. ■

Four Bands on a Bamboo Pole

—try a Chinese vertical slanter on 10 through 40

William R. Stocking WØVM
1030 Weidman Road
Manchester MO 63011

Many of us hams like to work DX. My friend, Harry, who lives down the street, had worked many DX stations. I had worked no DX at all! I asked Harry what I could do to work DX.

"Get a long, bamboo fishpole and build a vertical J like mine," he replied. "Get the bottom of the antenna higher than the electric light wires. Get the thing resonant, and you'll work across the big pond."

Harry was my "consulting engineer," and taking his advice usually brought good results. I purchased a 23-foot bamboo fishpole and mounted it high on the house using some lightweight 1 by 2 lumber. A vertical J antenna was suspended from the top of the fishpole. The matching stub was tuned to frequency, and the 600-Ohm open-wire feedline was attached and adjusted for the best transfer of rf energy into the antenna system. As usual, Harry was right. I got a big thrill the next day when I worked my first European station!

Seeing the big bamboo fishpole, one of my friends called it a "Chinese antenna." When I mentioned this to Harry, he laughed and remarked, "Maybe we can shanghai some DX." Since that time, bamboo fishpoles have been used in most of my vertical antennas, and the "shanghaiing" has been very good. (Fiberglass fishpoles 20 feet long also work well in antenna construction, but they are more expensive and are hard to find.)

This article will present information from some books and a magazine article and explain how this information was applied in making a four-band "Chinese vertical slanter" antenna system that is the best non-beam DX antenna that I have ever used.

In the December, 1978, *73 Magazine*, antenna axioms were presented.[1] Among these were: (1) The antenna system should be resonant at the frequency being used. (2) The rf from the antenna must be effectively put into the antenna. (3) There is no substitute for height; the higher the antenna, the better. (4) At easy-to-attain heights, vertical antennas have lower angles of radiation than do horizontal antennas. This makes them good for DX.

Because of their lower angles of radiation, vertical antennas have been known to outperform horizontal beams in making DX contacts, especially in cases where the horizontal beam was not any higher off the ground than the center of the vertical antenna. The value of low-angle radiation in working DX is beautifully explained in Capt. Paul Lee's book in Chapter 1, "Optimum Design For DX."[2] This chapter also contains other valuable information useful to antenna designers.

Vertical antennas longer than a quarter wavelength radiate rf at lower angles to the horizon than do quarter-wavelength ground-plane antennas. The angles of a quarter-wavelength ground-plane antenna are from 10 to 55 degrees. For a 3/8-wavelength vertical antenna, the angles are from 8 to 40 degrees. A half-wavelength vertical's angles are from 5 to 35 degrees. The angles of a 5/8-wavelength vertical are from 3 to 27 degrees.[2] For 3/4-wavelength verticals, "there is some slight deterioration of the low angle vertical pattern, but this is not serious."[3]

Vertical antennas longer

than a quarter wavelength also have power gain as compared with a quarter-wavelength ground-plane antenna.[4] A half-wavelength vertical antenna has a power gain of 1.8 dB as compared with a quarter-wavelength ground-plane antenna. A 5/8-wavelength vertical antenna has a power gain of 3 dB as compared with a quarter-wavelength ground-plane antenna. One can surmise also that a 3/4-wavelength antenna has some power gain as compared with the ground-plane antenna.

From this information, it is clear that vertical antenna lengths between 1/4 and 3/4 wavelengths will be better for making DX contacts than the popular coax-fed ground-plane antenna. To use these ideas in a multiband vertical antenna, tuned feeders must be used to take the rf from the transmitter to the radiating wires. When tuned feeders are used, balanced antennas can be built with wires almost any length, provided that *the length each side of the tuned feeders is the same.* Furthermore, such an antenna can be "loaded up" and used on several bands.

My friend Harry was somewhat impressed with this information. He suggested, "Why don't you make a chart comparing a tuned-feeder vertical with the popular trap vertical that is about 22 feet tall? After you get that one figured out, figure out what length of wires would make the best all-around DX antenna for 40, 20, 15, and 10 meters."

My "figuring" was as follows. For all practical purposes, the trap vertical is a quarter-wavelength ground-plane antenna on all bands, with the highest frequency radiators closest to the ground. As such, the angles of radiation with respect to the horizon are from 10 to 55 degrees on all bands. Except for the 40-meter band, on which all 21½ feet radiate, the trap vertical does not have its radiating antennas as high in the air as does a 22-foot "vertical slanter." (Axiom No. 3: "There is no substitute for height.")

With the vertical slanter, all 22 feet radiate on all bands. With respect to power gain and angles of radiation, the vertical slanter has the following as compared with the ¼-wavelength ground-plane antenna with its 10 to 55 degrees angles of radiation on all bands: On 10 meters, the vertical element is 5/8 wavelengths with a gain of 3 dB and angles of 3 to 27 degrees. On 15 meters, the vertical element is 1/2 wavelength with a gain of 1.8 dB and angles of 5 to 35 degrees. On 20 meters, the vertical element is a bit shorter than 3/8 wavelength, would have some gain as compared with the trap vertical, and the angles of radiation would be somewhat lower than those of the trap vertical.

With a ground-plane antenna using 4 equally-spaced radials, the radials do not radiate because the fields of the radials cancel out each other. Drooping the radials increases the gain of the ground-plane antenna.[5] Therefore, it is logical that a vertical-slanter tuned doublet, or a one-radial tuned ground-plane antenna might have some gain compared with a quarter-wavelength ground-plane antenna because there are no other radials to cancel radiation from the lower half of the antenna.[6]

Another great advantage of a vertical-slanter tuned doublet is that it can be tuned to exact resonance at any frequency, phone or CW, on any band, 10, 15, 20, or 40 meters. This means that the antenna will load up equally well on phone and CW in all of these bands.

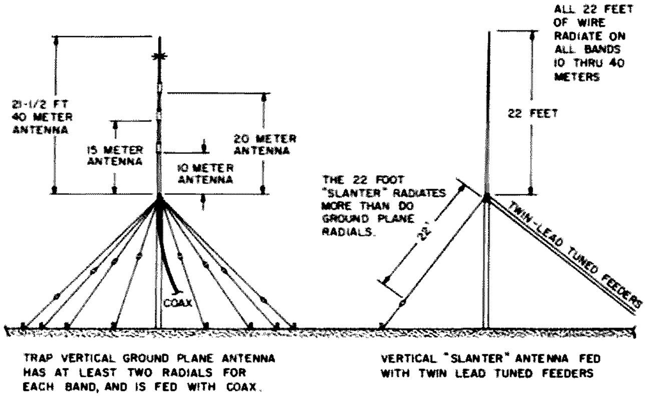

Fig. 1. Typical trap vertical and "vertical-slanter" four-band antenna fed with tuned feeders. The bottom of each vertical element is 20 feet above the ground.

Harry made this suggestion: "When you figure the best wire lengths for your four-band DX vertical slanter, make the wires as long as you can without degrading the performance on 10 meters. Of course, if you want better performance on 40 and 20 meters and don't care about 10 meters, you could make your wires as long as possible without degrading the 15-meter performance."

With this in mind, I chose 26 feet as the wire-length for the best performance on 10, 15, 20, and 40 meters. Twenty-six feet is 3/4 wavelength for 10 meters. If I did not care to work 10 meters, I would have chosen 33 feet, 3/4 wavelength for 15 meters.

The gain and angles of radiation for the 26-foot wire vertical-slanter antenna are conservatively stated as follows: 10 meters (3/4 wavelength), "guesstimated" 2.5 dB, with angles 5 to 35 degrees; 15 meters (5/8 wavelength), 3 dB, with angles 3 to 27 degrees; 20 meters (.39 wavelength), "guesstimated" 1.4 dB, with angles somewhat less than the 10-50 degrees of a quarter-wavelength ground-plane antenna. On 40 meters, 26-foot-long wires would work better than 22-foot-long wires.

Since in theory a vertical-slanter antenna fed with tuned feeders seemed to be much better than a four-band trap vertical, I decided to build one and try it out. I had an old, used piece of no. 12 Romex, 25' 8" long. This was very close to 26 feet, so I took out the two wires and used them in the antenna. A bicycle whip taped to a bamboo fishpole clamped to a small sailboat mast supported by two 8' two-by-fours clamped to a fence post was used to support the vertical part of the antenna. The black wire was taped to the supporting structure as the vertical element. (The black color helped to absorb heat and melt the ice after an ice storm.) The white wire was used as the slanter which was drooped down and out towards the south. 300-Ohm twinlead was used for the tuned feedline. The "Chinese vertical slanter" antenna looked interesting, but would it really work?

I thought that 40 meters would be the band on which the antenna would be least effective. (If thought of as a one-radial tuned ground-plane antenna, the vertical element is less than a quarter wavelength long. If thought of as a center-fed tuned

doublet, the total antenna length is a shortened half wavelength.)

On Friday, December 8, 1978, I decided to try out the antenna on 40 meters (worst band first!). The first station called, DJ4IT (West Germany), came back with a 579 report. At the end of this QSO, SP7EJS (Poland) was calling and reported a 559 signal when contact was made. After supper, LZ1KUF (Bulgaria) was called, but he did not come back. (I was not sure whether or not he had called CQ.) The next two calls resulted in QSOs. DL7PR (West Germany) reported 569, and YU1QFX (Yugoslavia) reported 599. (I suspect that this report was exaggerated for the sake of international goodwill. Hi!) These QSOs convinced me that the antenna worked well on 40 meters. Since that time, with very little time on the air, many DX QSOs have been made on 20, 15, and 10 meters. On several occasions, the DX station chose to answer me instead of one of the other stations calling him. This "Chinese vertical slanter" antenna is the best non-beam antenna that I have ever had. After a storm took down my quad, I could continue to have fun working DX.

Remember that a vertical slanter fed with tuned feeders will load up equally well on both CW and phone frequencies. The above-described antenna even loaded up and made a few contacts on 80 meters. However, the wires are much too short for good performance on the 80-meter band.

For even better performance, a system of radials each about 35 feet long, buried in the ground, could be added to the antenna system. The center of the radials should be under the vertical element. The more radials, the better. However, the antenna works well without radials as the above information indicates.

I have no trap vertical with which to compare the "Chinese vertical slanter" using on-the-air contacts. Certainly DX can be worked using trap verticals and other coax-fed groundplane antennas. However, antennas with more gain, lower angles of radiation, and more effective feed systems will certainly outperform any comparable coax-fed groundplane antenna when it comes to making DX contacts.

I think you'll enjoy the "Chinese vertical slanter antenna." Build one, use it, and find out for yourself how good a non-beam antenna can be for working DX. ■

6. This idea does not take into consideration ground losses. It might be that four drooping radials, each the same length as the vertical element, would enhance the performance of the antenna because there would be less ground loss. Radials buried in the ground under the vertical-slanter antenna might improve its performance, and they are suggested near the end of the article.

The Triton IV Goes QRP

—simply and efficiently

C. Stewart Gillmor W1FK
Spencer Road
Higganum CT 06441

My last tube rig (I sold it 20 years ago) had something like 1400 volts at 300 mA on the plates of the final tubes. It amuses me, while getting good reports on 20 meters, to glance at a meter and see that I am running 3½ volts on the finals of my Triton IV! Basically, this is a good way to run the popular Ten-Tec Triton transceiver efficiently at very low power input levels. In this article, I will show how you can modify the Triton IV for such operation and yet drill no holes and make no changes which could not easily be redone to put the rig back into original specifications. This idea originated with Mac Harper W1FYM, who made the same modifications to his Triton IV and suggested I modify mine so that our two rigs could form the basis for the portable QRP station at W1FYM/1 for Field Days 1977 and 1978. The Field Day setup was battery-powered, including our computer logging and TV monitor equipment, and it has performed quite well through 2 Field Days. But the computerized QRP Field Day station is another story . . . one that W1FYM must write.

The modifications described here allow the Triton IV not only to operate very efficiently at 10 Watts input for Field Day, but also they allow such operation any time you wish, merely with the changing of the 6-connector power plug to the transceiver. The design idea could easily be altered to suit other solid-state rigs as well. Now you may say, "But my solid-state rig is easily capable of QRP operation as is. I just back down the drive to the finals until I'm drawing about 0.8 Amps at 12 volts and I'm running about 10 Watts input." "Ah, yes," I reply, "10 Watts input, but very little output!" Instead of 1 or 2 Watts out, your rig could be putting 6 or 7 Watts out for the same 10 Watts input if you ran the finals more efficiently. A good way to do this is to run them at much lower voltage. A very satisfactory choice for the 5-to-10-Watt power class is about 3.5 volts. The necessary modifications for this are described in two parts: modifications to the Triton IV and construction of an integrated circuit variable voltage regulator.

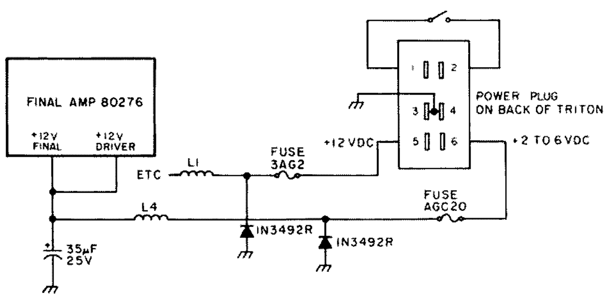

Fig. 1. Schematic of Triton IV as modified for efficient QRP operation.

Modifying the Triton IV

Basically, what we want to do here is allow the driver and final amplifier transistors to have their own voltage feed separate from that which feeds the rest of the transceiver and auxiliary equipment. Ten-Tec uses a 6-connector power plug and socket to run power leads and ac switching from the model 252 and 262 power supplies to the transceiver. Pins 1 and 2 are for ac switching and need not be altered. Pins 3 and 4 are grounded and likewise may be left untouched. Pins 5 and 6 are for +12 V dc. This pair is originally soldered together at the power plug to reduce pin resistance. To modify the Triton IV, proceed as follows (refer also to Fig. 1): Separate pins 5 and 6 at the power plug at the left rear of the Triton IV. Resolder the red #14 stranded wire onto pin 6 alone. Follow this red wire to its other end, through the AGC 20-Amp fuse to the cathode end of the 1N3492R diode (diode D1), at the 3-terminal strip. Disconnect this red #14 wire from diode D1 and run it in a 2-turn loop through the ferrite bead directly to the "+12 Final" terminal on the back of the final amplifier metal box; solder it securely. The "+12 Final" terminal is the large one with the solder lug. What you have now done is make pin 6 on the power plug of the Triton dedicated to providing dc solely to the driver and final amplifier transistors. For

safety, in case you mistakenly reverse your battery polarity, it might be wise to buy another 1N3492R high-power diode and install it across the line to ground in reverse-bias polarity position. This can be mounted on the opposite end of the 3-terminal strip from the other 1N3492R diode. Solder the cathode end (marked with a bar) to the #14 red wire going to the final amplifier transistors and the anode end to ground. Then, should you goof and reverse the battery leads (such as happened at 3:00 am in the middle of Field Day to yours truly), the diode will conduct, blow the 20-Amp fuse, and save your rig.

Now, take a new (say, orange-colored) piece of #14 stranded insulated wire and solder it to pin 5 of the Triton power plug. Push it through one of the cable holes in the metal shielding around the low-pass filter section and leave a few inches extra. Now take a small screw-mounting 3AG fuse holder and mount this to the outside of the low-pass filter shield. There is a screw very near coil L4 on the low-pass filter board which holds the board to the shield. The fuse holder can be mounted very easily on the back side of this aluminum shield. No holes need be drilled. Note: The toroid-core coil, L4, on the low-pass shield board is not the same coil as "L4" in my Fig. 1. The latter is a ferrite bead through which the final dc supply line is wound for 2 turns of rf shielding.

Now that you have mounted the 3AG fuse holder, connect your orange wire to one end and install a small, 2-Ampere fuse in the holder. From the other end of the fuse holder, run the same size orange wire along parallel to the back of the final-amplifier metal box until it reaches the 3-terminal strip where diode D1 is mounted. Solder the orange wire to the near end of the terminal strip; this is the same point where the cathode end of diode D1 and also 2 small #24 red wires are soldered. You have now completed the Triton modification. The orange wire from pin 5 of the power plug runs through a 2-Amp fuse and continues on to supply +12 V dc to all of the rig except the driver and final stages. Your regular 6-connector power socket from your model 252 or 262 power supply will work the same as before except that now you have the option to supply pins 5 and 6 on the power plug with different dc voltages if you choose. A way to supply different voltages is described below.

Variable-Voltage Regulation Using an IC Regulator

All you really need to do to supply the Triton final transistors with low voltage for highly efficient QRP operation is provide dc at from 2 to 6 volts at anywhere from 1 to 5 Amps. If you already have a small multi-voltage dc supply, fine. Or you can consult one of the ham handbooks and find a circuit which supplies dc at only a single voltage level. This would work perfectly well, for you can vary power input of the Triton using the drive control. I will describe here a variable-voltage regulated supply which provides 2 to 6 volts out and easily handles 5 Amperes (see Fig. 2). This was constructed in W1FYM's shack in one evening using some purchased and some scrap parts. The circuit was mounted on PC board. I purchased a heat sink somewhat larger than necessary, and the pass transistor (HEPS7004) is rated at 15 Amps! Since the case of this large power transistor is not at ground potential but at +12 V dc, we mounted the circuit board on the heat sink, which in turn was mounted on 2 insulating pieces of nylon scrap. The μA723 IC was mounted in a socket rather than being soldered. I always avoid soldering IC chips, if possible, because everybody ends up frying a chip now and then and it's a lot easier to test or change a chip which is socket-mounted.

Ten-Tec sells a small accessory 625-mV meter (ammeter model 207) which plugs into the various power supplies of their 250 and 260 series, using a phono plug. We wanted to monitor our current input during Field Day and other QRP operation but didn't want to buy or permanently install a meter, so we put a phono jack on the board and wound a wire shunt of about 0.7 Ohms value so that the meter reads 5 Amps full scale. Of course, you could use a different meter movement with a different shunt value. The 1k pot is an Ohmite ANP 102K or similar and its value, as well as that of the 330-Ohm ½-Watt resistor, is not critical. The IC used by us was a Fairchild μA723, but equivalents are available from firms including Motorola (MC1723), National (LM723), and Signetics (μA723). Q1 is a 1-Ampere-rated pass transistor, Texas Instruments TIP29B or equivalent; Q2 is the 15-Ampere-rated HEPS-7004. We used #12 stranded copper wire with large battery clips to supply the 12 V dc from the battery to the regulator power plug (pin 5 and pins 3-4). I would recommend using #14 or #16 stranded copper wire from the emitter of Q2 to the shunt and on to pin 6 of the power socket.

The construction and use of the regulator is straightforward. The 1k pot can easily be adjusted for output voltages from about 2 to 6 volts. W1FYM has had only to replace one fried IC chip in a year and a half of occasional use and I have had absolutely no troubles at all. Believe it or not, I've often had 579 and 599 reports on both CW and SSB into Europe and South America on 20 meters. Those reports aren't due only to the Triton IV QRP . . . I use long vee-beams 6 to 8 wavelengths on a leg and multi-element wire collinear beams at my QTH. Still, I've described a fairly-easy-to-make modification to the Triton IV and the construction of a modest voltage regulator which not only makes for a competitive Field Day rig, but also allows one to use a medium-powered solid-state rig such as the Triton in highly efficient QRP operation. ■

Experimenter's Corner: The MM5369N

—how many uses can you find for this one-chip crystal oscillator?

Charles B. Patten
4641-4 Chicago Drive
Andrews AFB MD 20335

Would you like a simple, versatile, crystal-controlled oscillator? Would you like it to operate from below 500 kHz to over 16 MHz, with rich harmonic content, simply by changing crystals? Too good to be true? Read on, it gets *better*!

The MM5369N—see Fig. 1(a) and (b)—is a CMOS integrated circuit that is configured to provide a crystal oscillator (you supply the crystal) with a buffered output (maximum available load about 500 uA) and an internally-connected divide-by-59659 (or $2^{15.864452175}$) divider chain which provides, in the manufacturer's intended use, a 60 Hz output for dc-operated digital clocks when used with an inexpensive 3.579545 MHz crystal. This, and numerous other uses, will be mentioned as we proceed.

How It Works

The crystal oscillator is biased by a crystal and RC network (Fig. 2) consisting of R1, C1, and C2. R1 is nominally 20 megohms to bias the oscillator stage for class A operation.[1] Capacitor C1 provides the necessary parallel capacitive load, which, with R1, causes the oscillator to start reliably. C2, in parallel across X1-C1, permits the oscillator output to be trimmed to an accuracy of ±100 ppm of the desired operating frequency with an accuracy of ±2 ppm obtainable with careful component selection.

The buffered oscillator output frequency is available at pin 7 of the IC which gives you a convenient point to monitor the oscillator output without loading, while trimming to the desired operating frequency. The buffered output is at CMOS levels, and for that reason must drive only CMOS-compatible circuits. If other than CMOS levels are required, it will be necessary to provide the needed digital or analog buffers. Several CMOS-to-digital-level buffers are available from many of the suppliers listed in the advertisements in this magazine; additionally, all parts called for in this article are available from Surplus Electronics, 9600 Baltimore Blvd. (rear), College Park MD 20740. The CMOS-to-analog-level buffer is not available as a single chip, but may be constructed in the form of a one- or two-transistor amplifier to allow the oscillator to be used in just about any circuit configuration you can imagine. These can include local oscillators, QRP transmitters, frequency counters, and so on. Note that the output

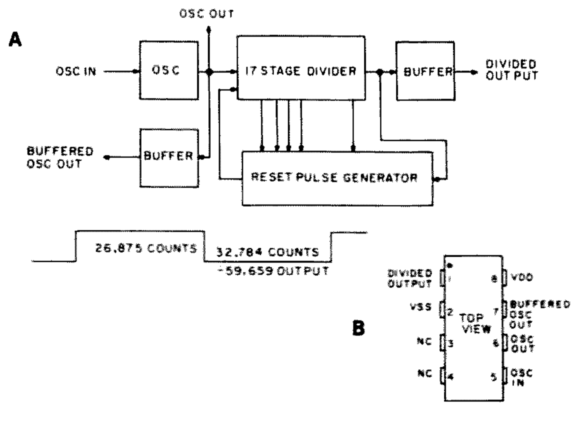

Fig. 1. (a) MM5369N block diagram and timing.[1] (b) MM5369N pinout.[1]

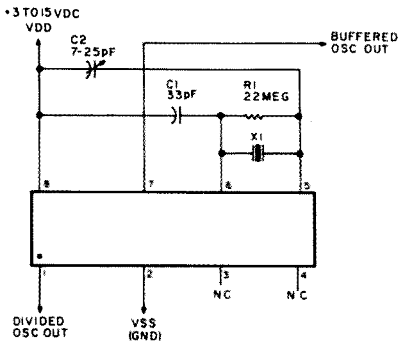

Fig. 2. Basic operating circuit.

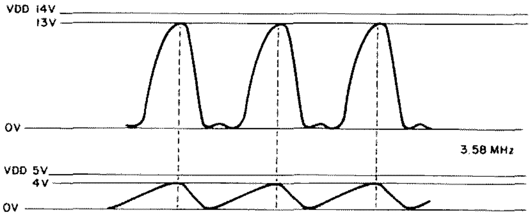

Fig. 3. Output waveforms taken at 3.58 MHz from pin 7. (Note loss of rise and fall times at very reduced Vdd.)

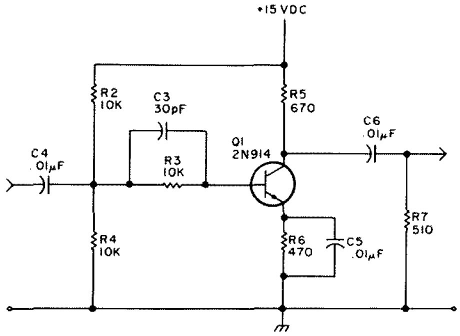

Fig. 4. Modified buffer amplifier for CMOS-to-analog level translation.[3]

load on the buffered oscillators output must be kept below 500 uA to avoid exceeding the manufacturer's specifications.

The divider section in the standard MM5369N is a mask-programmed, 17-stage divider set to divide the input frequency by 59659. This is accomplished in conjunction with a six-input reset pulse generator which, by virtue of its mask programming, sets the internal divisor length. The MM5369 is also available with custom mask programming. Should you have the need and the bucks (kilo, no doubt), National Semiconductor would, most likely, happily mask-program a few thousand for you with any divisor from 10000 to 98000. The divided output duty cycle stays very close to 50% for a Vss of 8-15 volts and can drop as low as 20% for a Vss of 3 volts at the same frequency. The current drain is nominally 2-4 mA for frequencies of 500 kHz to about 6 MHz, with up to 20 mA drawn for frequencies up to 16 MHz.

Operational Considerations

The MM5369N is a versatile crystal oscillator chip requiring a bare minimum of supporting parts for proper operation. The oscillator is very tolerent of supply voltage variations, and the only noticeable effect of an abnormal voltage change is a possible loss of duty cycle and a degradation of the rise and fall times of the output waveform (see Fig. 3). Although the MM5369N is specified to operate from dc to 2 MHz at 6 V dc and dc to 4 MHz at 10 V dc, I have found that the oscillator will run reliably in excess of 16 MHz at 10-15 V dc with a very good sine-type output.[1] Also, if you are inclined to experiment, you will find that the crystal can be replaced by an inductor and the circuit operating range extended to about 40 MHz. But you will pay the price—not too exorbitant—in the loss of crystal stability and output voltage level.

Although the output of the oscillator is already buffered, I feel it is advisable when using this circuit in any application to add at least an additional stage of isolation, whether it is digital or analog, to avoid undue loading of the oscillator. The output load should be limited to less than 500 uA and be as low as possible for best stability. This is not difficult to obtain with a one- or two-transistor buffer amplifier (Fig. 4). The amplifier was adapted from "Brew Up a Signal Generator" (*73*, January, 1978). The circuit as shown has been tested from 500 kHz to 16.5 MHz, operates quite reliably, and adds only an additional 20-25 mA to your power supply requirements. If you are planning to operate this buffer amplifier exclusively under 5 MHz, you can omit the 30 pF capacitor across R3.

Stand-Alone Crystal-Controlled Calibrator

So far you have been presented with a bunch of theory and "how to" and little else. Here's your chance to include all of the above plus a little more and have a reliable test instrument standard for your lab. First dig out that old 1- or 10-MHz rock you bought at the last hamfest. We're going to combine it with the MM5369N, a TTL buffer amp, a few ICs, and end up with a crystal calibrator with multiple divided outputs. It will serve you well when the time comes to calibrate your scope, and, in between, serve as the timebase for a frequency counter, if you wish. The output of pin 7 on the MM5369N (Fig. 5) is fed to the TTL buffer amp and then to the first 7490; each

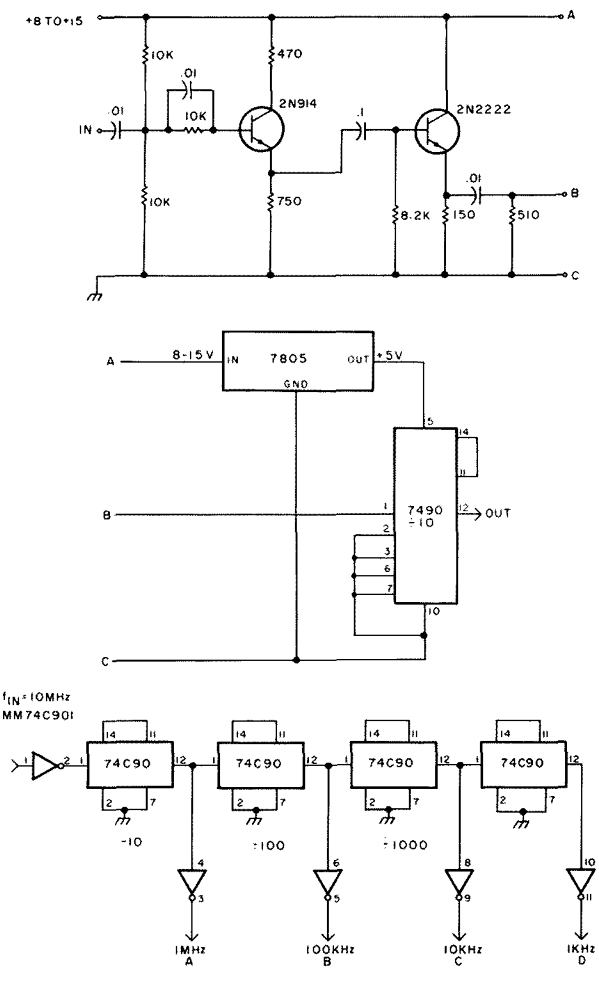

Fig 5. TTL digital interface and divider chain.

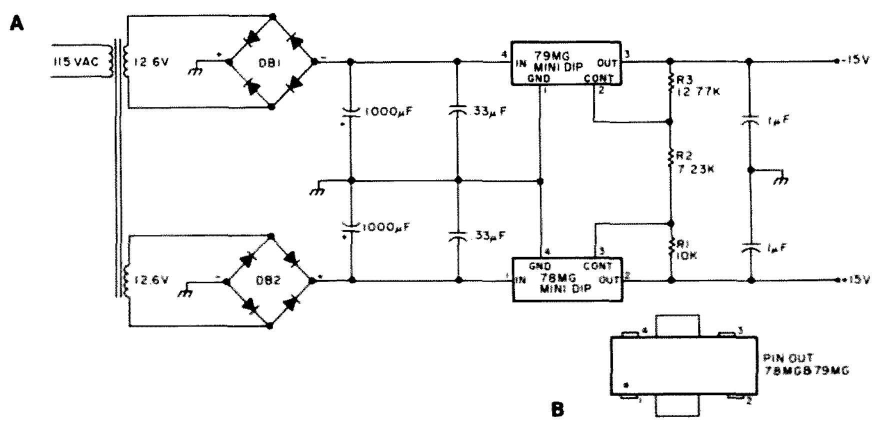

Fig. 6. (a) UA78MG and UA79MG power supply. The negative portion of the supply is not required for this project. It is provided to allow the user greater latitude in using the power supply in other projects as well. (b) UA78MG and UA79MG pinout.

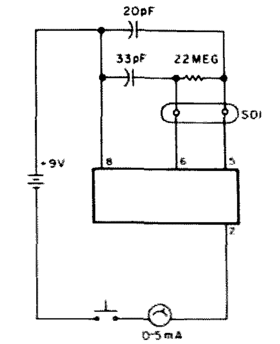

Fig. 7. Crystal checker schematic.

divided signal is then fed to the following IC stage in turn. At each 7490 output, the signal is brought out to a TTL buffer chip where it is available for use as you please. At approximately 100 kHz you may wish to substitute 74C90s for the 7490s to keep the current drain to a minimum.

If you choose this route you should use 74C901 or 74C902 CMOS-to-TTL buffers. These outputs are fed, in turn, to a rotary switch and from there to the output. There is also a signal provided that has been divided by 59659 that is available at pin 1 of the MM5369N. This also can be buffered and used as a known signal *source for a* press-to-test function if you use this circuit for a frequency counter timebase. You will note that the TTL buffer is a two-stage amplifier driving a conventional 7490÷10 IC. This is necessary as it still is difficult to find 74C90s that operate at 16 MHz. So far we have touched on the parts required to have a crystal oscillator but we don't have a source of power to run it—yet.

The Power Source

The power source—see Fig. 6(a) and (b)—is a simple voltage-regulated source that will help eliminate the aforementioned "abnormal voltage drop." It consists of the usual transformer, full-wave diode bridge, and capacitor arrangement followed by a really neat voltage regulator chip, the UA78MG, made by Fairchild Semiconductor. The UA78MG is a 4-terminal positive voltage regulator (UA79MG is the negative version) which is adjustable from 5 to 30 volts at a current of 500 mA. This versatile device can be used with a series pass transistor for higher output currents when needed.[2] For those who are interested in the gory details of how to design power supplies with this chip, a few of the basic rules I have found to be useful are set forth below:

1) Set the control current through R1, R2, and R3 to 1 mA.

2) The UA78MG control voltage is 5 V, the UA79MG is 2.23 V. R2=7.23/1 mA=7.23k Ohms. If the power supply is just plus or just minus, then that respective leg is referenced to ground, and R2 is the control voltage divided by the control current.

3) The value of R1 and R3 is found by Rx=Vout (desired)−Vcontrol/Icontrol.

4) If you prefer an adjustable supply, R1 and R3 can be replaced by trim pots and their respective voltages set independently.

5) Include a .33-uF input and a .1-uF output capacitor for each circuit to improve the circuit's output transient response time.

If you wish, a 25-volt center-tapped transformer may be modified to provide the dual output voltages called for by Fig. 6. Take a *sharp* knife and carefully follow the c-t lead through the paper until you find the point where the lead is soldered to the output winding. When you find this point, carefully unsolder and split the two winding wires, attach separate output wires, and cover the connections with the proper size heat shrink or tape. Re-wrap the transformer with tape, *check for shorts*—and you're done.

Other Nonstandard Uses

Other nonconventional uses include a portable crystal checker (Fig. 7). Just add a 0-5-mA meter, and replace the power supply with a 9-volt transistor battery. Note and mark the

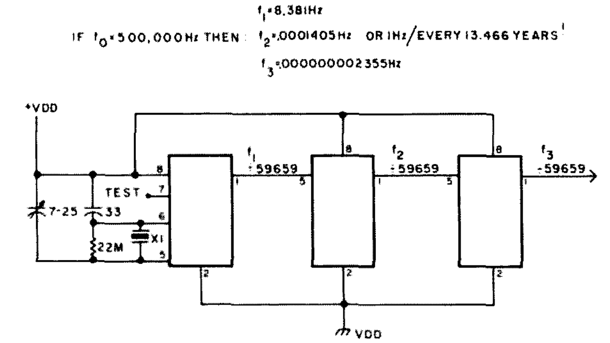

Fig. 8. Long-interval timer-option schematic.

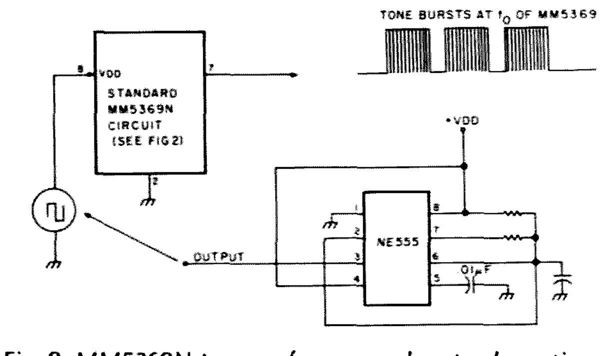

Fig. 9. MM5369N tone or frequency burst schematic and block diagram.

current drawn without a crystal in the circuit and mark this on the face of the meter. Crystals that operate at 5 MHz and below will cause a current drop from the mark, while 7 MHz and above will cause the current to increase. If there is no charge in the amount of current drawn, then the crystal is open, or very close to 6 MHz.

The MM5369N also can be used as a long-interval timer. You can cascade the MM5369N without using the active oscillator part of the IC by feeding the output of the first oscillator (pin 1) to the input of the next oscillator (pin 5). (See Fig. 8.) By this scheme, you select the desired output period and multiply by 59659 or multiple thereof, and find the inverse to get the operating frequency needed. If you wish to have 1 Hz every 1.88 years you have to use an operating frequency of 3.579545 MHz and divide it through 3 MM5369N dividers to obtain the desired output.

Another option is to use the MM5369N as part of a tone or frequency burst oscillator (Fig. 9). The NE555 timer provides a low frequency square wave that is used to supply power to the Vdd pin of the MM5369N. Every time the square wave goes positive, the oscillator is gated on for the duration of the positive portion of the pulse. The oscillator will produce whatever frequency has been selected for it by its crystal.

Construction

These circuits can be wired either point-to-point or by printed circuits. Although my circuit debugging is started on perfboard or breadboarding strips, I have always found it more enjoyable, in the long run, to make all my test equipment on printed circuit board. Not only does it make assembly easier, but when properly accomplished, can add to the usefulness and longevity of a circuit. Should you also find this to be the case, PC layouts have been included (Fig. 10).

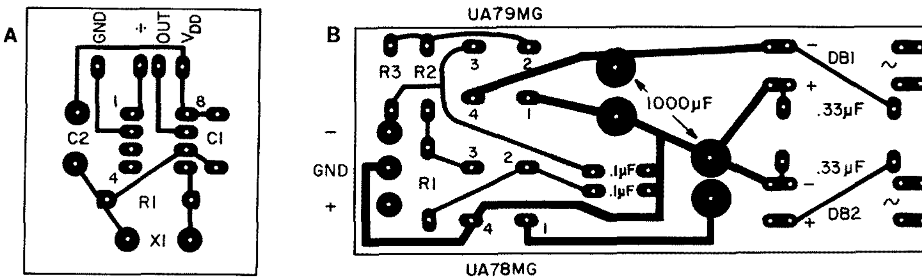

Fig. 10. (a) MM5369N PC board layout for basic circuit and crystal checker. (b) UA78MG and UA79MG power supply PC board layout. Both PC board layouts are shown from the component side.

Calibration

Calibration of the MM5369N output frequency is a relatively simple matter and can be accomplished with a bare minimum of fuss. Hook the output of pin 7 on the MM5369N to an oscilloscope or frequency counter and trim C2 until the desired frequency is obtained. Do this slowly as the trim cap is small and it's easy to overshoot the desired frequency. If you opt for the counter method of calibration and your counter drifts very little, you can record the oscillator output over a period of time while recording the ambient temperature, and make a frequency vs. temperature chart that will allow you to temperature-compensate your oscillator. This is done by finding the rate of frequency drift with temperature and selecting a replacement capacitor for C1 that has the opposite coefficient of the temperature curve. To select the proper capacitor, note the frequency and temperature at several points. Divide the difference in frequencies (desired and actual) by the desired frequency, then divide the result by the number of degrees that have changed from your ambient setting and you should have your temperature coefficient in parts per million/degree. This is what capacitor temperature coefficients are expressed in. Simply choose the one that is closest to the opposite of your recorded findings and you will be on your way to maximum stability.

Conclusion

This article is intended to present the experimenter with a versatile, crystal-controlled building block that proves to be useful in a wide range of circuits and is functional as a general-purpose crystal-controlled frequency standard that is not limited to such a mundane chore as a digital clock timebase. ■

Digital Readout Rotator Control

—can the microcomputer connection be far behind?

Modernize your TR-44.

Randy Kaeding K8TMK
222 Jamesway
Benton Harbor MI 49022

With almost everything switching to digital readout these days, I decided to design a new control box for my TR-44 rotator. For my own personal use, the new control box would have to: use LED displays, be relatively simple, interface directly to the rotator with no internal modifications, remain accurate during ac line variations, and match my other station equipment.

Photograph of the new control box. (The display was enhanced so that it would stand out better.)

Research

Fig. 1 shows the schematic of the TR-44's unmodified sensing circuit. This circuit is a simple voltage divider, which causes more or less current to flow through the meter as the sensing potentiometer (inside the rotator) changes position. When the potentiometer is at the bottom end of its range (rotator fully counterclockwise, as viewed from the top of the rotator), no current flows through the meter, and the meter needle remains in the resting position. When the rotator is at the top end of its range (rotator fully

clockwise), approximately one milliampere flows through the meter, and the needle indicates full scale.

With the above ideas in mind, I decided that a simple dc voltmeter, with proper voltage scaling, could be used to indicate the position of the rotator potentiometer. If you apply a voltage to the potentiometer so the wiper-voltage changes from 0 to 3.6 volts during a complete revolution, you have a voltage which changes at the rate of .01 volts per degree.

A preliminary data sheet for the Motorola MC14433 integrated circuit, which is

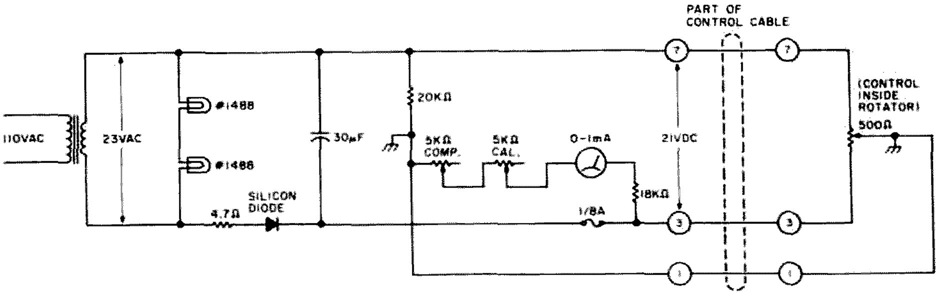

Fig. 1. Unmodified sensing circuit for the TR-44 rotator.

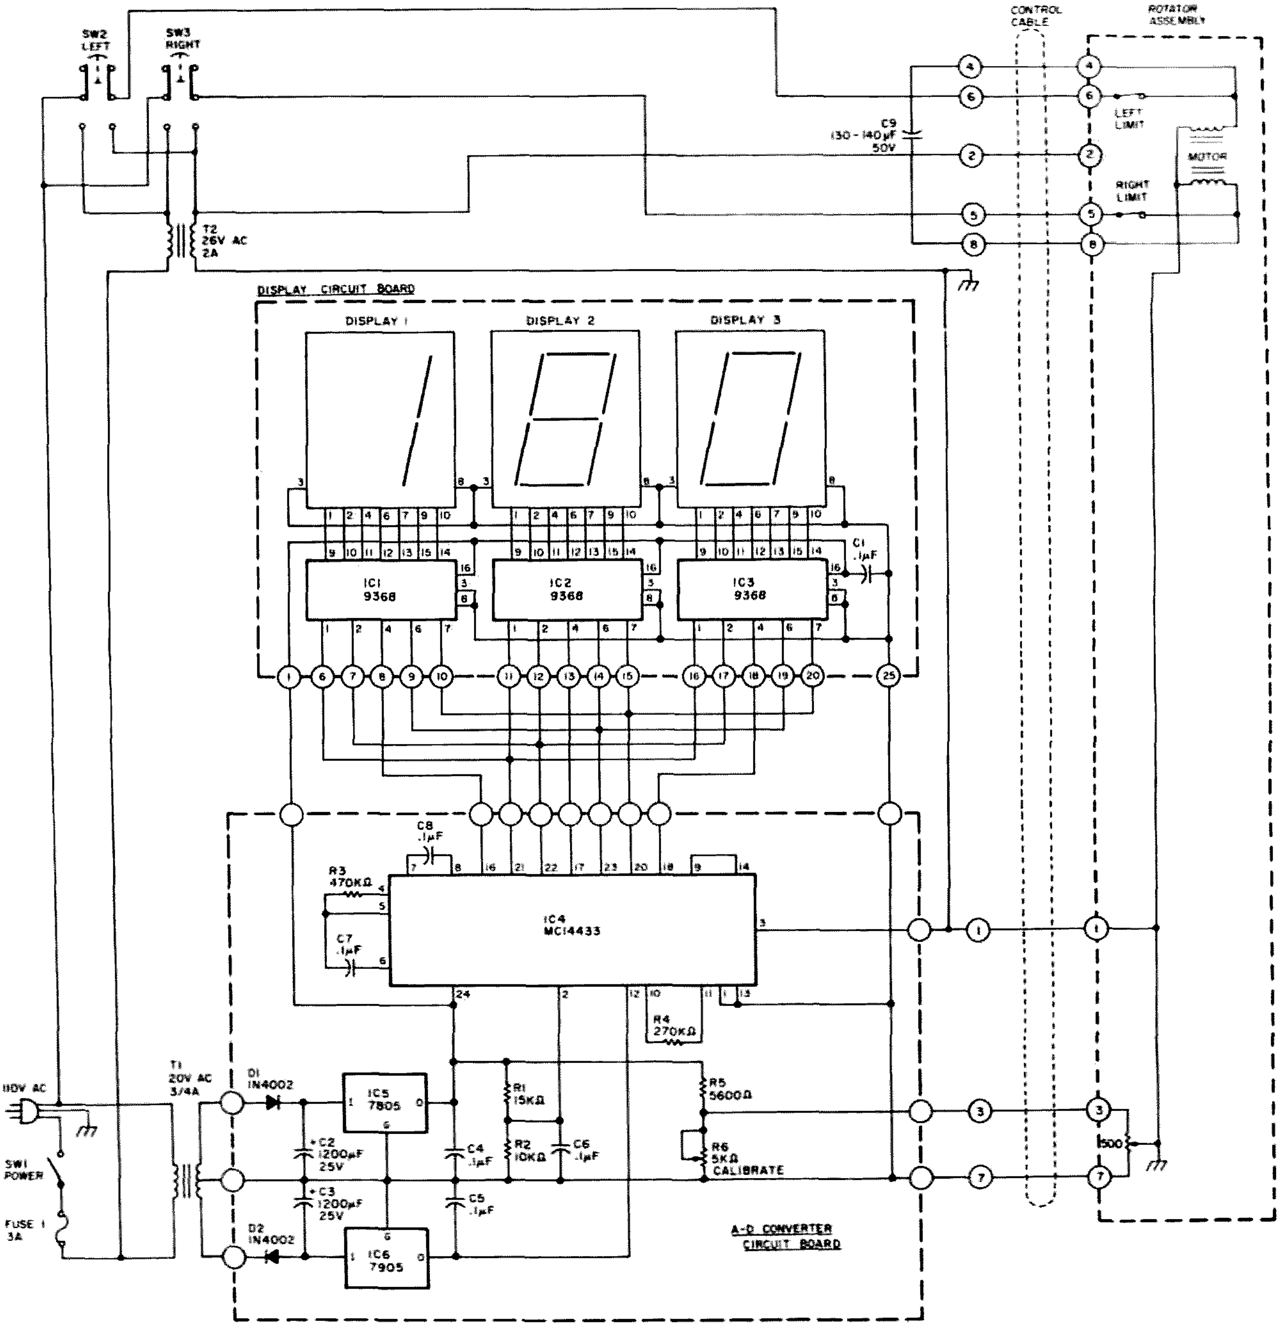

Fig. 2. Schematic diagram of the new control box (shown connected to the original rotator assembly).

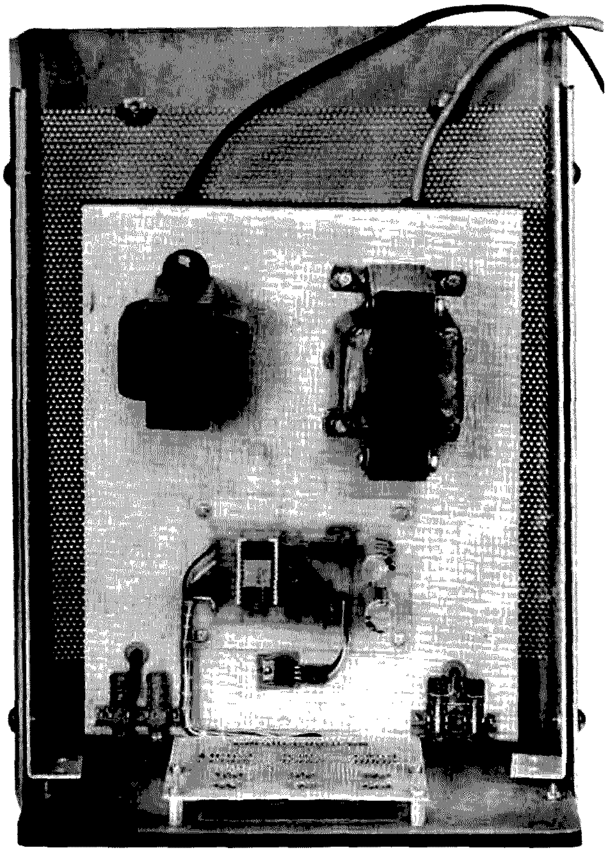
a 3½-digit analog-to-digital converter, contained the schematic of a simple 3½-digit digital voltmeter. To suit my particular requirements, I deleted the overrange and polarity sensing circuitry to further simplify the circuit. I then modified the circuit to work with some decoder-driver ICs and LED displays that I already had. Fig. 2 is the schematic diagram of the completely redesigned rotor control box (shown connected to the rotator assembly).



Internal layout of the new control box.

Construction

With one minor exception, construction of the control box is not critical. Since the potentiometer wiper inside the rotator is mechanically grounded to the case (control cable wire #1), you must take care to keep all other circuit points isolated from ground.

If you use the same +5-volt regulator as I did, heat-sink it to the chassis. Be sure to use an insulator between the IC and the chassis to keep it electrically isolated from the chassis. The −5-volt regulator IC does not need a heat sink and may be mounted on the circuit board.

Figs. 3, 4, 5, and 6 show the foil and component layout of the two circuit boards. Although the two circuit boards could have been combined into one, I used separate boards so that they could be used on future projects.

Be sure the power transformer you use in the sensing circuit has at least an 18-volt, center-tapped, secondary winding. This will allow the regulator ICs to remain within acceptable operating parameters with varying ac line voltages. With a 20-volt, center-tapped transformer, you should be able to keep an accurate display indication while the ac line voltage varies between 90 and at least 130 volts.

I mounted an extra pushbutton switch on the left side of the front panel to help balance the appearance of the panel. You

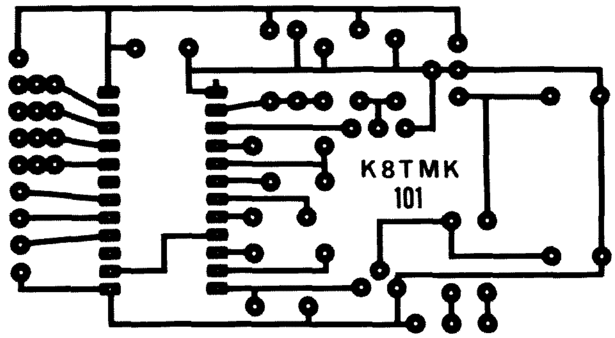


Fig. 3. Actual size foil pattern for the A-D converter circuit board (shown from the foil side).

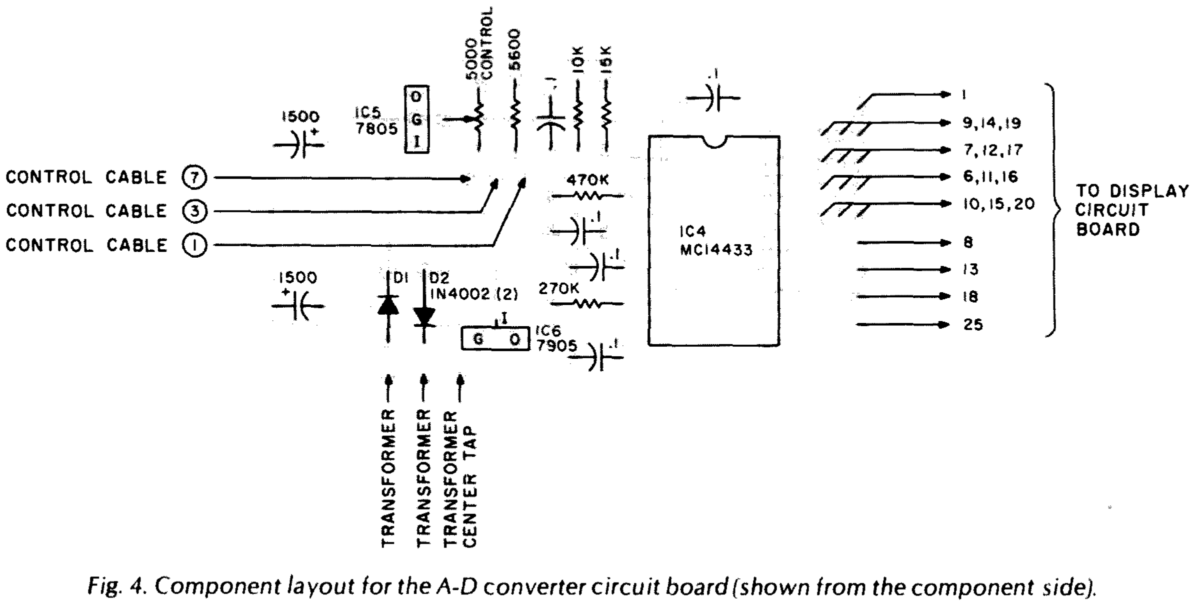

Fig. 4. Component layout for the A-D converter circuit board (shown from the component side).

could use this switch for brake release, if you use the control box with the Ham-M rotator.

Calibration

Calibration of the new control box is quite simple. You should not have to repeat it unless the ac line voltage changes drastically or the length of the control cable changes.

Connect the new control box to your rotator control cable and depress the POWER button. Use the RIGHT push-button to turn the rotator to its fully-clockwise position. The display will stop changing when you come to the end of travel. *Note:* If the display goes toward zero as you turn the rotator in a clockwise direction, interchange control cable wires 3 and 7. Now adjust the control on the A-D converter circuit board until the display indicates 360. The display should automatically indicate 0 when you turn the rotator to the left end of travel.

Operation

To determine the position of your antenna, simply depress the POWER button. The display will indicate the position in degrees. If you desire, you can leave the POWER button depressed for a continuous indication.

If you wish to turn the rotator to a new position, simply push the LEFT or RIGHT button until the display indicates the desired position.

Conclusion

I have been using the new control box for a few months with no noticeable problems. It is a great pleasure to hear a DX station, look up his bearing in a table, and turn the rotator to the exact position without having to interpolate between the lines on an analog meter.

In the future, I plan to redesign the control box for use with a microprocessor. This will allow me to punch in a prefix on a keyboard, for example, and then simply wait for the rotator to reach the correct position automatically. ■

Parts List

Component Number	Description
C1, C4, C5, C6, C8	.1 uF disc ceramic capacitors
C2, C3	1200 uF, 25-V electrolytic capacitors
C7	.1 uF mylar™ capacitor
C9	130-140 uF, 50 V, non-polarized capacitor
D1, D2	1N4002 silicon diode
DISP 1, DISP 2, DISP 3	FND-500 LED displays
F1	3-Ampere, 3AG fuse
IC1, IC2, IC3	9368 7-segment decoder-driver-latch ICs
IC4	MC14433 3½ digit A-D converter IC
R1	15k Ohm, ¼-Watt, 5% resistor
R2	10k Ohm, ¼-Watt, 5% resistor
R3	470k Ohm, ¼-Watt, 5% resistor
R4	270k Ohm, ¼-Watt, 5% resistor
R5	5600 Ohm, ¼-Watt, 5% resistor
R6	5k Ohm linear control
SW1	DPDT locking push-button switch
SW2, SW3	DPDT momentary-contact push-button switch
T1	Power transformer (20 V ac center-tapped, ¾-Ampere secondary)
T2	Power transformer (26 V ac, 2-Ampere secondary)

Build the KIM Keyer

—with a 3-message memory

Marvin L. De Jong KØEI
Dept. of Math-Physics
The School of the Ozarks
Pt. Lookout MO 65726

The short application program listed in Table 1 allows the KIM-1 to send any of three messages by pressing one of three keys (A, B, or C) on the KIM-1 keyboard, and, with the interface circuit shown in Fig. 1, the KIM-1 becomes an electronic keyer as well. Any microcomputer with a 650X microprocessor and one of the MOS Technology PIA or VIA chips may be used with only minor modifications to the program. An important feature of the program is the ability to precisely set the code speed between 5 and 99 words per minute by entering the speed, in decimal, at storage location 0000 in memory. The program converts this decimal number to hexadecimal, then does a division routine to convert the speed to a time duration of the basic dot element, and the interval timers on the 6530 PIA do the rest.

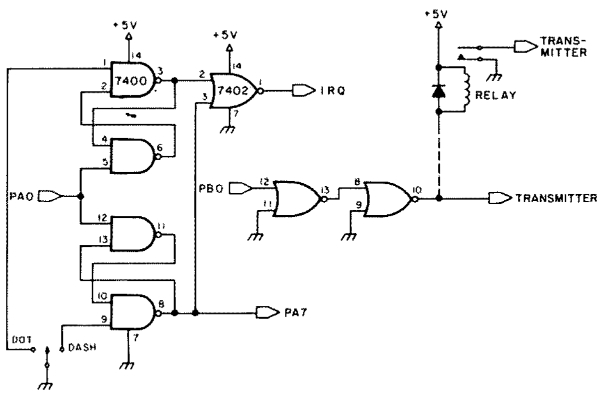

Fig. 1. Interface circuit. Some transmitters may require the optional relay for keying, with a 1N914 diode across the coil for protection against transient voltages. The Triton IV may be keyed directly from pin 10 of the 7402. All grounds should be the same as the KIM-1 ground, and the 5 volts may be stolen from the KIM-1 power supply.

Anyone who does much contest operating will realize how useful an automatic message sender is. Even the casual CW operator can use it for sending CQ or other routine messages. Code tests for Novices can be programmed and sent at precisely 5 wpm by storing the entire test in memory. At 5 wpm, at least 5 minutes of code may be sent. For Field Day (1977), we used a similar program to send CQ CQ CQ FD DE KØEI KØEI K as message A, then when a station responded, we sent (   ) DE KØEI UR 599 MO 599 MO K, where the blank was the call of the station to be keyed by the operator, after which he hit key B to give the remainder of the message. It worked very smoothly with no discernible pause between the call letters and the message. (Don't try to look up our score, because KØEI was not the call we used.) The operation of the keyer is exactly like most electronic keyers; holding the paddle in the dot position will cause a series of dots and spaces to be sent. Dashes occur with the paddle in the dash position, and the timing of all the characters is controlled by the program and the crystal on the microcomputer.

Operation

Assuming the program has been loaded and the interface circuit connected, operation proceeds as follows. The code speed at which you wish to operate is loaded into storage location 0000. Any decimal number from 05 to 99 may be put into this location. Next, the starting and ending addresses of each message must be loaded into memory. Since all three messages are in page 2 of memory, only the low-order bytes of the starting and ending addresses need be given. Suppose message A starts at 0200 and ends at 0251, message B starts at 0252 and ends at 0265, while message C starts at 0266 and ends at 0278. (These are completely weird numbers chosen at random from my skull and have absolutely no other significance.) Then one would load 00, the starting address of message A, at location 0001; 52, the starting address of message B goes in at 0002; and 66 is entered at 0003. The respective ending addresses go into memory locations 0004 to 0006, that is, 51 into 0004, 65 into 0005, and 78 into 0006.

How do you load the messages themselves? For each character you want to send, you must load the corresponding hex number shown in Table 2. Suppose, for no reason whatsoever, message A is to be "DE KØEI K" and is to start at 0200. You then load the hex numbers 90 40 00 B0 FC 40 20 00 B0 from locations 0200 through 0208; 00 goes into 0001 and 08 into 0004.

Probably the best way to proceed is to first load the three messages including spaces, noting the starting and ending addresses of each message on a piece of paper. Then go back to page 0 and put the starting and ending addresses in their proper locations. Go to location 0300 and hit the GO button to start the program running. Test to make sure everything is working before you put the thing on the air.

Programming Details

The flowchart shown in Fig. 2 and the comments in the program should give the reader a good feeling for the structure of the program. It consists of three principle parts: the main program, subroutine SEND, and the interrupt routine, all of which have individual flowcharts shown. Minor components are subroutine DIT (which holds PBØ at logic 0 for the dot length followed by a logic 1 for the space length), subroutine DAH (which holds PBØ at logic 0 for three dot lengths—1 dah = 3 dits—followed by a space), and subroutine TIMER (which loads the timer on the KIM-1 with the precise length of 1 dot and then waits for this time to elapse).

We now look at some specific details of the program. The speed in words per minute must be converted to hex before the computer can do any further calculations with it. This conversion may best be explained with an example. Suppose we wish to operate at 20 wpm, so 20 is entered into location 0000. What we mean by 20 is 2 in the tens place and 0 in the ones place, but what the computer thinks this means is 2 in the sixteens place and 0 in the ones place. At least we agree on the ones place, so initially we mask the ones place out with an AND statement; later we retrieve it and simply add it to the result of our decimal-to-hex conversion of the 2. To trick the computer into thinking the 2 in the sixteens place is the 2 in the tens place we intended it to be, we change the sixteen to a ten with this trick: $10 = 16/2 + 16/8$. The sixteens place divided by two is accomplished by one shift-right statement (LSR), while the sixteens place divided by 8 is accomplished by three shift-right statements. So, the 2 in the sixteens place is shifted right once, stored, shifted right two more times, and these two results are added. We now have 2×10 in the computer (in hex, of course) rather than 2×16. Adding the results from the ones place completes the conversion.

Using the keying speed definitions from *The Radio Amateur's Handbook*, one can calculate that the dot length in milliseconds is 1200/S, where S is the code speed in words per minute. If the divide-by-1024 timer on the KIM-1 is used, 1 count corresponds to 1.024 milliseconds. Converting the dot length to timer counts gives TIME = (1172/S) base 10 = (494/S) hex, where TIME is the number to be loaded into the divide-by-1024 timer to give a code speed of S wpm. So, the computer must divide S into 494. This is determined by successively subtracting S from 494 until the result becomes negative. The number of subtractions is the quotient of 494/S.

Pin PBØ on the KIM-1 is used as the keying output from the computer. When power is applied to the computer and the reset button is depressed, PBØ comes up in a logic 1 state. This dictates that logic 1 corresponds to the transmitter being off. Consequently, PBØ is buffered and inverted twice by the NOR gates. Inverters such as the 7404 would work, but since I needed a NOR gate in the keyer interface, I simply used the other NOR gates on the same

chip. If PBØ could sink enough current, it might drive the relay directly, but I preferred the buffering shown in Fig. 1. Mark elements of the Morse code are sent by decrementing (DEC) PBØ for the appropriate length of time, while space elements are sent by leaving PBØ at logic 1.

The program idles in the loop starting with JSR GETKEY and ending with BNE RPT, testing each of three keys (A, B, and C) to see if they were depressed. If no key is depressed, the program remains in this loop. If a key is depressed, register Y is set to 0, 1, or 2 depending on which key was struck. Y is then used as an index to look up the starting address (low-order byte of page two of memory) of the message (STRT,Y) and later the ending address (END,Y) of the message. The starting address is used as an index to find the first code element of the message (MEM,X), and it is incremented until the ending address is en-

Table 3. Storage locations to be loaded by the operator.

countered.

The conversion of an 8-bit word of memory to a Morse code character has been described in other references in detail and will not be repeated here. There are a number of schemes available,[1,2] but the most efficient schemes appear to be those in references 3 and 4, and those were the techniques used here.

The keyer is implemented by the interrupt routine, which in turn uses subroutines DIT, DAH, and TIMER. It will send at exactly the same speed as the messages. The keyer interface circuit is simply debouncers which are reset at the end of an interrupt. If the key is still in the dot or dash position, the reset has no effect and another interrupt occurs. The flowchart indicates that the state of PA7 determines which element is to be sent.

One last thought: If you want to be able to key in a few characters in the middle of a message, just load a few word spaces there and key the characters in when the blank occurs. This is handy for giving signal reports and also in some contests where the number of contacts is updated after each QSO. ■

No More TRS-80 Cassette Woes

—E-Z Loader does the trick

Paul L. Goelz WA9PUL
2228 Madison Place
Evanston IL 60202

David F. Miller K9POX
7462 Lawler Ave.
Niles IL 60648

You can eliminate most of your Level II TRS-80 cassette-loading problems once and for all! It's true, the circuit described in this article will go a long way toward eliminating your CLOAD problems. If all of the data is there on the cassette, this gadget will find it and load it into your TRS-80 Level II machine . . . it's the greatest thing since the Level I manual!

If you've worked with Level II for any time at all, you know that it is somewhat sensitive to playback volume on a CLOAD command (what an understatement!). Playing back a *good* recording through this circuit—let's call it the E-Z Loader—will allow you to set the playback volume on the Radio Shack CTR-41 recorder anywhere from 2 to 10! A *not-so-good* recording will have somewhat less range, but it will still be quite broad, and you *will* be able to load it. Even the head azimuth (vertical alignment of the record vs the playback head if not the same machine) becomes fairly noncritical, and you can even vary the playback volume up and down while loading with no adverse effect.

Sound too good to be true? It seems that in this day and age we're besieged with all manner of claims and counterclaims, but E-Z Loader really works . . . try it and see for yourself!

The Problem

When you type CSAVE and ENTER, the TRS-80 puts out a positive- and negative-going square wave at the cassette port. However, when the audio recorder "processes" this square wave and lays it down on tape, it isn't exactly square any longer. Take a peek at Fig. 1 and see what we mean!

The output of the cassette recorder as depicted in Fig. 1(b) is more like a mostly negative-going spike, broadened out, with a small (in ratio) positive dimple on either side. This is what a *good* recording looks like; a *bad* one is downhill from that! Somehow, the TRS-80 will accept that waveform and load the data it contains into RAM, if the recorder/playback head azimuth is quite close and the playback level is just right!

This is where the circuit of Fig. 2 comes into action. The root of the problem lies in the TRS-80's resident software. After the computer recognizes a sync pulse, it waits a short time and then looks at the input once again. If there is a pulse present, the computer interprets it as a 1 and goes through the cycle all over again. If there is no pulse present, the computer assumes this to be a 0 and repeats the cycle.

This sequence occurs until all of the data has been loaded from the tape, at which time the READY prompt reappears. The problem in all of this, however, is in the *amount of time* that the TRS-80 waits after recognizing a pulse, before it looks for the next pulse, and *not* in the input level, as many believe!

Currently, a Level II TRS-80 waits only about 250 microseconds before testing for a pulse, and therein lies the problem. A *good* tape will produce a pulse that is much narrower than 250 microseconds—see Fig. 1(b)—but a *bad* tape, or one in which the head azimuth of the record machine differs from the playback machine, can easily produce pulse widths in excess of that magical 250 microsecond figure! When that happens, the computer interprets the tail end of the initial pulse as a new pulse, and there goes your CLOAD!

The E-Z Loader corrects this by waiting for a sync pulse, triggering and producing an output pulse 150 microseconds wide and then locking-out for 750 microseconds (2/3 of the time between a sync and data pulse), triggering again if a data pulse (logic 1) is present, and outputting it as a 150-microsecond-wide pulse. Thus, no matter how wide your input pulses are, they can produce only 150-microsecond-wide output pulses.

In a nutshell, the E-Z Loader circuitry takes the rather poorly defined spike of Fig. 1(b) and regenerates it back into a nice square, narrow pulse again. Your computer will really love that narrow pulse and will

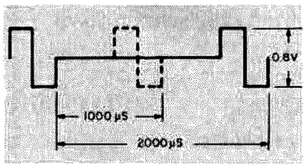

Fig. 1(a). Output directly from the cassette port of the computer. Sync pulses are solid lines; data pulses are dotted lines.

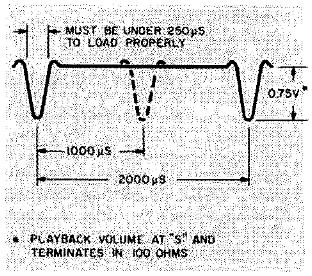

Fig. 1(b). The output from a good cassette tape after being recorded by the CTR-41 recorder. Sync pulses, solid; data pulses, dotted.

continue to reward you for your effort.

How the Circuit Works

Following the schematic diagram (Fig. 2) from the cassette player output (which is the input to the E-Z Loader), you'll notice that we transformer-couple in order to make the bridge rectifier behave properly and to eliminate the ground loop condition that exists in the Radio Shack CTR-41 recorder (in case you haven't eliminated it already by other means).

The input signal to the transformer first passes through a high-pass filter (C5 and R10) and is stepped up by a factor of at least 10. It is then applied to the bridge rectifier whose output consists of only positive-going pulses. These positive pulses are sent to the base of transistor Q1, but with a slight twist.

Locate R7 and C4 on the schematic and notice that Q1's base current must pass through C4. As pulses are rectified by the bridge, C4 charges to a voltage equal to the output of the bridge (less 0.6 V) and at the same time supplies a current spike to Q1's base, triggering the transistor. By the next time a pulse arrives, C4 has discharged slightly through R7, and again supplies a triggering current spike to Q1's base.

The net effect of all of this is that Q1, C4, and R7 form a passive level detector and trigger the rest of the circuitry only on pulse peaks, regardless of the level arriving from the recorder. The amplified and peak-detected pulses are fed to the first inverting input of the 74LS123 IC, which is a dual low-power Schottky retriggerable monostable multivibrator chip (say that three times!).

The two multivibrators in this package are connected in such a way that the output is taken from the Q output of section one, which also feeds the non-inverting input of section two. The $\overline{Q}$ output of section two is fed back to the non-inverting input of section one, which has the effect of disabling the output of section one for a 750-microsecond duration.

The total effect of all of this can be observed on an oscilloscope at pin 13 (or pin 10) of the IC: a positive-going square pulse, 150-microseconds wide, for every sync and data pulse leaving the tape, regardless of the width of the pulse on the tape. No hum, no noise, no miscellaneous crud to fool the TRS-80 into loading erroneous data . . . just nice, clean pulses. The buffer amplifier is an emitter-follower with a voltage gain somewhat less than unity, but it does a nice job of isolating and matching the 100-Ohm input impedance of the TRS-80 computer.

TRS-80 performance won't be affected by positive, negative or square waves (both transitions), so we chose positive pulses to keep the circuit parts count down. The pulses output to the computer are between 1 and 2 volts peak-to-peak (viewed on a scope with a 100-Ohm termination), regardless of where the CTR-41 recorder volume control is set, as long as there is at least enough volume to detect the pulses and trigger the E-Z Loader's circuitry. If the playback volume is too low, there simply will be no output (or possibly, sporadic output).

The point of minimum output for each cassette is easy to determine, however, and as long as you stay above that point, you'll get a good load. On a decent tape, this minimum can be 2 or 3 on the CTR-41's graduated volume control knob, and there

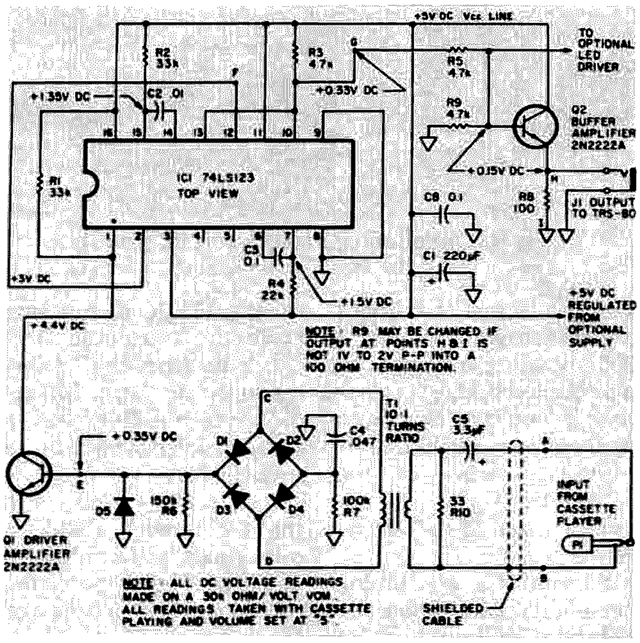

Fig. 2. TRS-80 E-Z Loader schematic diagram.

usually is *no maximum level*.

Precautions

One potential pitfall to properly loading with the E-Z Loader in-line (other than tape dropouts and/or bad data on the tape) would be insufficient level into the E-Z Loader, thus the optional LED driver shown in Fig. 3. The LED visually shows the operator that point at which the E-Z Loader is not receiving enough level from the recorder on playback. As long as the LED is lit and slightly flickering, the recorder output level control (volume) is set above this threshold. It also adds a nice touch in impressing visiting dignitaries.

It's an option because it has no effect on the rest of the circuitry and is for operator convenience only. To prevent occasional drops in level on the tape from causing a bad CLOAD, keep the recorder's output at least two divisions above the point at which the LED extinguishes.

Requirements

OK, we've talked you into building the E-Z Loader, now you probably think that there will be some sort of catch such as specially selected parts, critical circuit layout, and/or fancy test equipment needed for alignment. No! All of the parts are available from Radio Shack with the possible exception of the input transformer, which is actually an output transformer with a turns ratio of approximately 10:1. You can probably scrounge one from that defunct $9.95 portable transistor radio you've been putting off fixing. That's called recycling and it's the "in" thing to do.

The transformer is hooked up backwards so that the low impedance (speaker) winding is accepting the audio out of the cassette recorder. Resistors are all 1/4 or 1/2

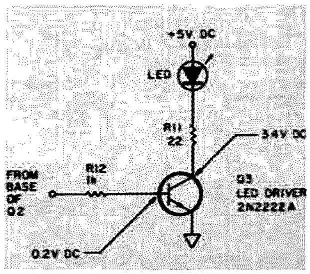

Fig. 3. Optional LED driver circuit.

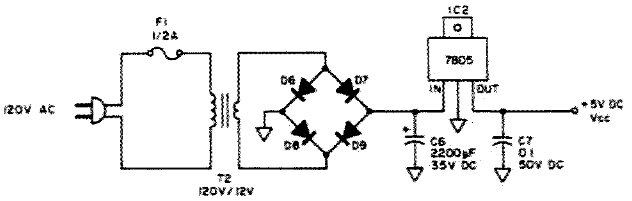

Fig. 4. Optional regulated 5-volt dc supply.

Watt units, and the diodes are silicon with at least a 200 piv rating. You can use a packaged bridge rectifier unit, or you may choose to wire up four individual rectifiers as shown on the schematic (Fig. 2). All capacitors are 35-to-50-V dc rating.

C2 and C3 are timing capacitors and should be polyester or tantalum for stability and accuracy of value. The 2N2222A transistors are medium-gain devices and also are not critical. Whether you use perfboard layout (as shown in the photo) or a printed circuit board, it would be advisable to consider using a socket for the 74LS123 IC (I just hate unsoldering 16 pins all at once).

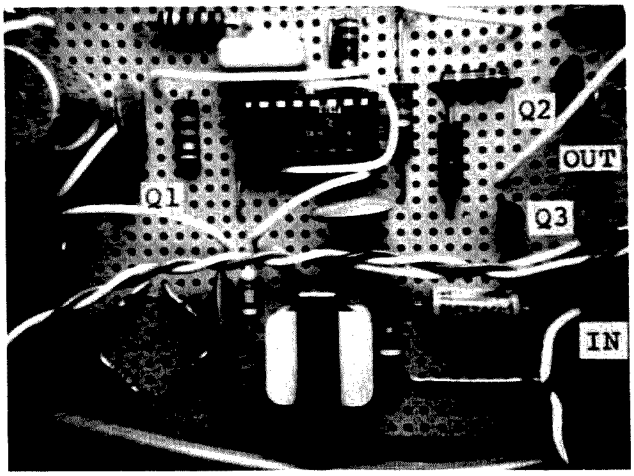
As you may have noticed, the E-Z Loader requires +5 V dc (at about 25 mA), and it should be quite close to that figure for the TTL IC to function correctly. You could steal +6 V dc from the CTR-41 through an appropriate dropping resistor, but a better choice would be to incorporate the supply shown in Fig. 4, along with the E-Z Loader board, in one neat self-contained package. The parts for the optional power supply and the optional LED driver are also available from Radio Shack. Now you don't have any excuse for putting off building the gadget!

Putting E-Z Loader to Use

There is no alignment or parts selection required. Voltage readings and oscilloscope waveforms at various points are shown to assist in verifying that the unit is functioning properly. Simply hook up the E-Z Loader between your CTR-41 recorder's "ear" output and the TRS-80's audio input and you're all set. Incorporating a 1/8-inch phone jack on its output and a 1/8-inch phone plug on its input will permit you to remove the E-Z Loader at any time and normalize your setup. But we honestly don't think that you'll be inclined to do that very often, not once you've seen how easy it is to CLOAD with the E-Z Loader in-line (except, perhaps, to demonstrate the difference to skeptical friends).

One other use for the E-Z Loader would be to clean up poor quality tapes. Using a second recorder, play the bad tape through the E-Z Loader and plug the E-Z Loader's output into the second recorder's aux input. The recording on the second machine will then be first quality, and should load on anyone's unmodified computer with ease.

Exceptionally high hum level on the tape being played back and wow (frequency instability) in the record or playback machines are other potential sources of CLOADing errors. The E-Z Loader helps in all cases, but obviously there are limits beyond



The perfboard layout used in one of the units that has been constructed.

Parts List

C1—220-uF electrolytic, R.S. #272-1029
C2—.01-uF printed circuit capacitor, R.S. #272-1065
C3—.1-uF tantalum capacitor, R.S. #272-1401
C4—.047-uF printed circuit capacitor, R.S. #272-1068
C5—3.3-uF tantalum capacitor, R.S. #272-1408
C6—2200-uF electrolytic, R.S. #272-1020
C7, C8—.1-uF ceramic disc, R.S. #272-135
D1 to D9—200-volt silicon rectifiers, R.S. #276-1102
F1—1/2-Amp, 1/4 x 1-1/4 inch fuse, R.S. #270-1271 mounted in R.S. #270-364 holder
IC1—74LS123 integrated circuit, R.S. #276-1926
IC2—7805 integrated circuit, R.S. #276-1770
J1—1/8-inch phone jack, R.S. #274-251
P1—1/8-inch phone plug, R.S. #274-286
Q1 to Q3—2N2222A transistor, R.S. #276-1617
R1, R2—33k, 1/2-W, 10 percent resistor, R.S. #271-040
R3, R5, R9—4.7k, 1/2-W, 10 percent resistor, R.S. #271-030
R4—22k, 1/2-W, 10 percent resistor, R.S. #271-038
R6—150k, 1/2-W, 10 percent resistor, R.S. #271-047
R7—100k, 1/2-W, 10 percent resistor, R.S. #271-045
R8—100-Ohm, 1/2-W, 10 percent resistor, R.S. #271-012
R10—33-Ohm, 1/2-W, 10% resistor, R.S. #271-007
R11—22-Ohm, 1/2-W, 10% resistor, R.S. #271-005
R12—1k, 1/2-W, 10% resistor, R.S. #271-023
T1—audio output transformer, 10:1 ratio or greater, such as Calectro #D1-729 (200-Ohm c-t to 8 Ohm)
T2—120 V ac to 12 V ac @ 300-mA transformer, R.S. #273-1385

Miscellaneous

Socket for IC1—16-pin DIP, R.S. #276-1998
LED—light emitting diode, R.S. #276-1622
Solder, hook-up wire, shielded cable, perfboard and cabinet
Note: C2 and C3 are timing capacitors and as such must be of good quality such as those listed above. Do not use disc types for this purpose.
A circuit board for the E-Z Loader and power supply is available from the authors. Send $6 and an SASE to Paul Goelz, 2228 Madison Pl., Evanston IL 60202.

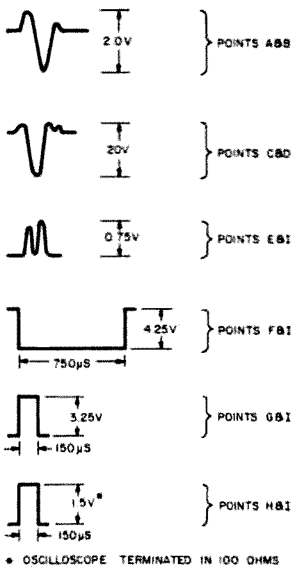


Fig. 5. Peak-to-peak oscilloscope measurement within the E-Z Loader's circuitry.

which very little can be done.

Keeping your recorder's head, pinch roller, capstan and tape guides clean will go a long way toward helping the E-Z Loader do its job. Using fairly decent cassettes without wrinkles on the tape, fixing sticking reels and poorly placed pressure pads, and watching out for nonuniform oxide coating are also your responsibilities toward good loading. As stated in the beginning of the article, as long as the data is on the tape, the E-Z Loader will go a long way toward digging it out and loading it into your TRS-80, but you will have to give it a fair shake at least!

It has been our intent to make public a circuit that is genuinely needed within the TRS-80 community. We intend no infringement on the rights of others, and reproduction of the circuit is granted on a not-for-profit basis only. I will answer all inquiries if the writers would be kind enough to enclose an SASE. ■

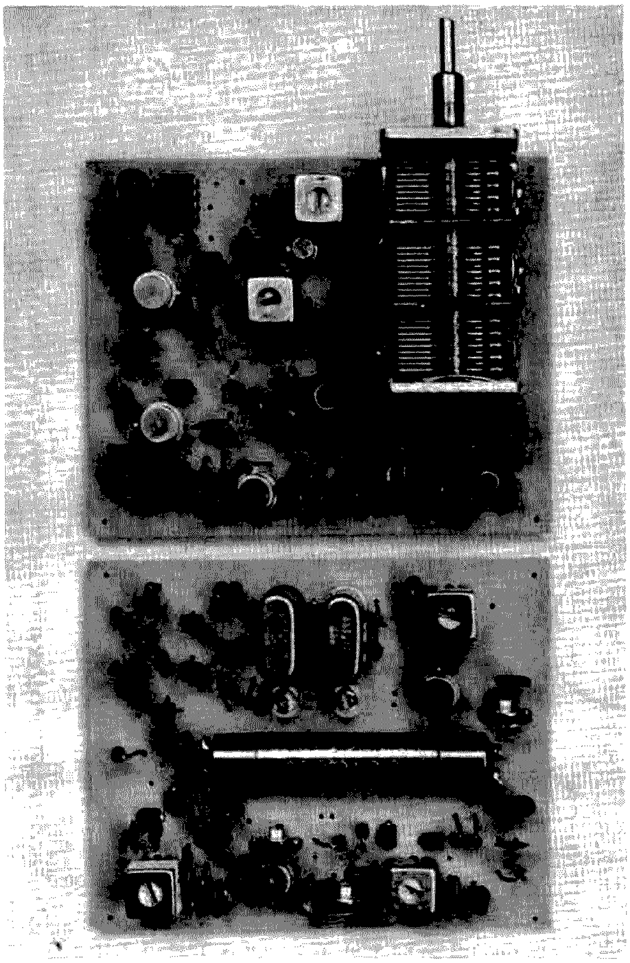
The Incredible Shrinking Transceiver

—build it on two tiny PC boards



Both boards fully assembled.

Ray Megirian K4DHC
606 SE 6 Avenue
Deerfield Beach FL 33441

Over the years, a ham's junk box can sport a pretty wild assortment of goodies, and mine is no exception. Many of the items are treasured for their sentimental value, some because they are of the often-needed variety, and the remainder simply because they cost a bunch. In this last category, I had stored away several Collins mechanical filters which by now had been with me so long that I couldn't remember how I had acquired them in the first place. On several occasions I had tried to sell or swap them, but no takers had appeared, so I decided I might just as well put them to use.

A Miniature Transceiver

If you are familiar with my Minicom series of receivers, you know I have a passion for miniaturization and it would seem logical that the filters be used in something small. The final choice was an SSB generator and receiver combination which would ultimately form the major portion of a transceiver. The entire project occupies 2 PC boards of identical size. Both boards are 3.7" x 3" and can be stacked if desired. The receiver portion is a simplified version of the Minicom MK V and covers 3.5 to 4.0 MHz. The transmitting exciter section output is also 3.5 to 4.0 MHz. By adding a suitable amplifier, the rig could be used as is on 75 meters. For use on other bands, additional mixers and a crystal oscillator would be used to heterodyne up to the desired frequencies.

Circuit Description

The Collins filters from my junk box are all housed

in the Y-style case which is cylindrical and for which the PC layout is designed. Of the 2 filters from the collection which were suitable for this application, one had a bandwidth of 2 kHz and the other 3.1 kHz. Both worked well in this circuit.

A complement of 6 integrated circuits and 8 transistors provide all the needed functions. One i-f stage, the vfo, and the bfo are common to both receive and transmit modes. The input to the mechanical filter and the output from the common i-f stage are transferred from receive to transmit by means of diode switches. The upper- and lower-sideband crystals in the bfo are also switched by diodes.

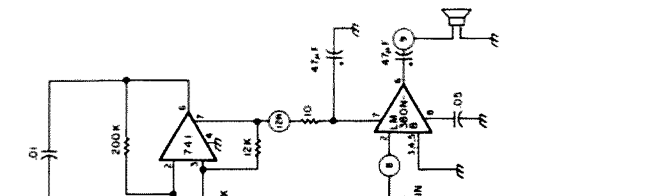
All the frills such as VOX, noise blanker, CW filter, S-meter, and other goodies were left out in the interest of miniaturization. When assembled sandwich fashion, the whole rig fits in the palm of your hand.

Speech Amplifier and Balanced Mixer

A CA3020 integrated circuit performs as both speech amplifier and balanced mixer, thus contributing substantially to our miniaturization efforts. This device, though designed for class B audio amplifier service, has a bandwidth of 8 MHz and lends itself to rf applications such as this. The chip houses an emitter-follower input stage, a differential amplifier, 2 emitter-follower drivers, and 2 output transistors. The output transistors have uncommitted collectors and emitters, which makes the device suitable for use in our circuit.

The mike feeds into pin 10 which is the base of the input emitter-follower. Input impedance is over 50k Ohms. R2 is a preset trimmer used to adjust the audio gain for the mike being used and, once set, can be left alone. The 455-kHz carrier is introduced across the emitters of the output transistors and a 50-Ohm preset pot is used to balance the signal. In some cases, cancellation of the carrier from the output may not be complete and capacitive balancing may be necessary. The PC board has provision for a small capacitor on either side of the balance pot to ground.

A modified transistor i-f transformer is used to couple the collectors of the output transistors to the mechanical filter. The winding data for this and other transformers will be covered later.



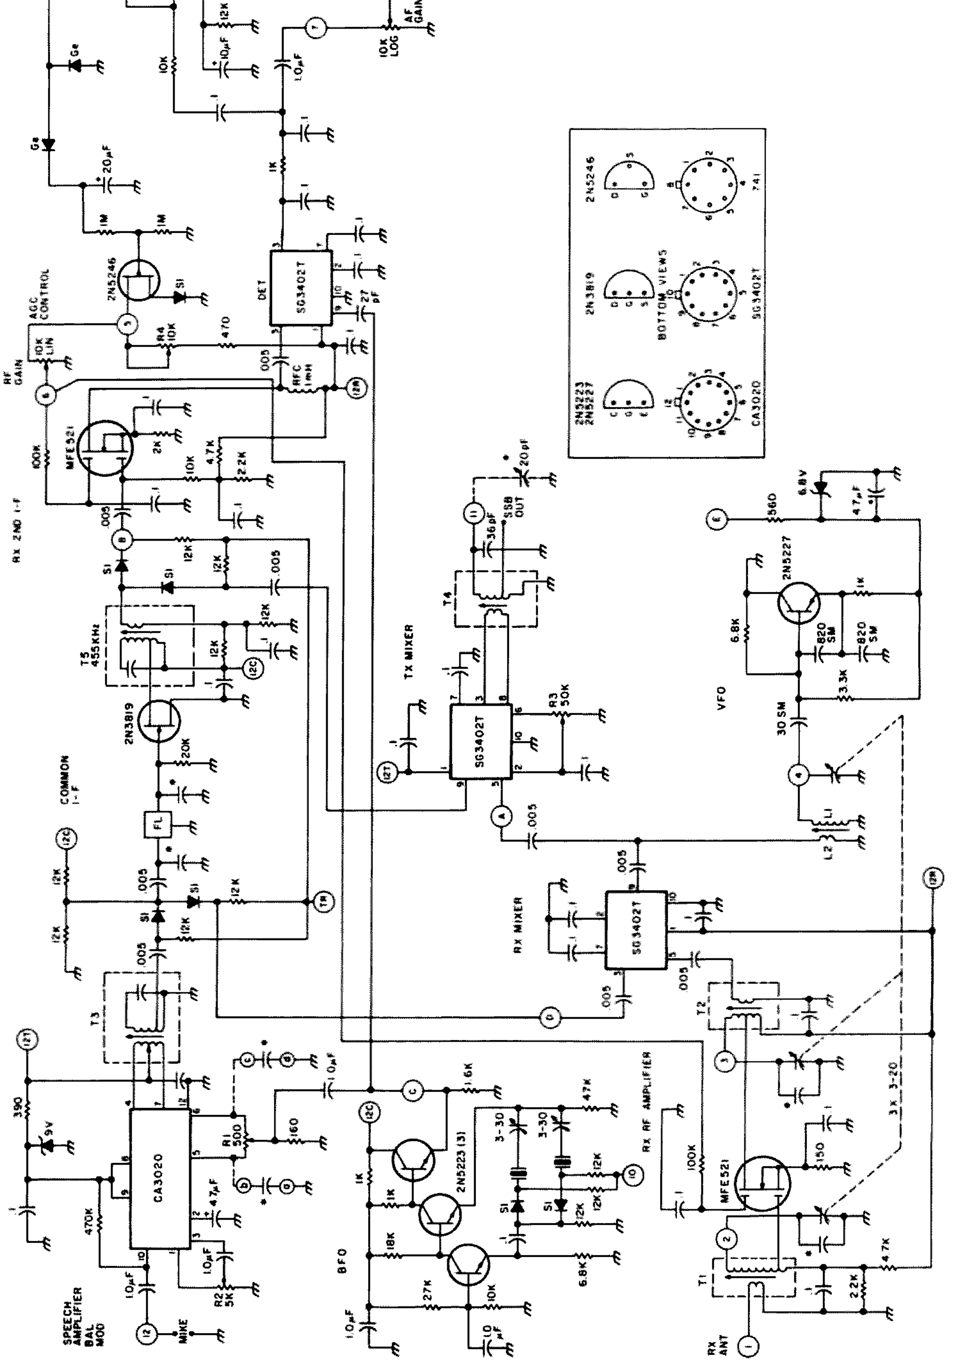


*Fig. 1. Complete schematic for the transceiver. Circled letters and numbers refer to pads on the PC boards. *See text. Si = silicon diode. Ge = germanium diode.*

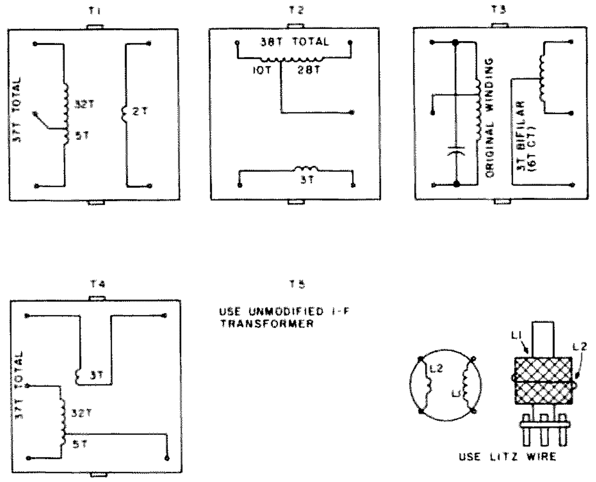

Fig. 2. Coil winding table. All bottom views.

I-f Amplifier

The SPDT diode switch at the input to the Collins filter connects it either to the transmitter mixer or to the receiver mixer output. Following the filter is a JFET amplifier that stays in the circuit for both transmitting and receiving. Then comes a second SPDT diode switch that routes the output to a second i-f stage for receiving or to a mixer for transmitting. The second i-f stage uses a dual gate FET with agc applied to gate 2.

Bfo, Vfo, and Transmitting Mixer

The bfo is crystal controlled and operates continuously since it is common to both receive and transmit modes. An SPDT diode switch selects the desired crystal for either upper- or lower-sideband operation.

The vfo tunes from 3.045 to 3.545 MHz. It is also a common circuit and operates continuously. It is actually a part of the receiver section and is the same circuit that has been used in the Minicom. The common vfo and bfo ensure that both transmitter and receiver will be on the same frequency. Since very little energy is required by the mixers, no buffers are used after the vfo. Output is taken from a 1-turn link wound over the tank coil.

The 455-kHz signal and the output from the vfo are mixed in an SG3402T IC balanced mixer. A 3.5-to-4.0-MHz output is produced and the vfo signal is nulled by means of the 50k preset trimmer, R3. The output transformer, T4, is fabricated from a standard transistor i-f transformer. A PC pad is provided for connecting a small variable capacitor of 20 to 30 pF across the coil for front-panel peaking at any frequency. A tiny solid dielectric type from a transistor FM radio is ideal for this purpose.

Receiver

All the circuits used in the receiver section are the same as the Minicom MK V. For those not familiar with the DMOS transistors, such as the Motorola MFE521 used in the rf and i-f stages, they require a fixed bias of around 4 volts on gate 1. This is provided by the 2.2k and 4.7k resistors which form a divider across the 12-volt supply. Gate 2 is controlled by agc voltage but, unlike the regular MOSFETs, need not go negative to attenuate the signal. The DMOS transistor works with all positive bias which simplifies the agc. R4 is adjusted so that the no-signal level on the agc line is 6 volts. The transistors will be working at close to maximum gain at this value of bias and a strong signal will drive this voltage down to 3.5 to 4 volts. A manual rf gain control is provided and would normally be mounted on the front panel.

The mixer is an SG3402T IC which provides substantial gain and, as mentioned before, places a very light load on the vfo. Output from the mixer is routed to the filter via the diode switch.

A third SG3402T is used as a product detector and feeds the LM380N-8 audio IC directly. Some of the audio output from the detector is fed to a 741 op amp where it is amplified and rectified to provide a positive dc voltage which charges the 20-uF tantalum capacitor across its output. Part of this charge is bled off by means of the two 1-meg resistors and applied to the gate of the 2N5246 agc control transistor. As the dc level increases due to strong signals, the transistor conducts more heavily and causes the voltage at the drain to drop. Since the drain is connected directly to the agc line, receiver gain is decreased and the purpose accomplished.

Filling in the Details

There are some numbered pads on the boards and some with letter designations. These notations also appear on the schematic and should aid in keeping the external wiring straight. The pads marked capital A, B, C, D, and E on both boards have to be connected together in pairs, that is, A to A, B to B, etc. Mating pads are directly above one another with the boards properly oriented and component side up. This allows stacking if desired. Pad A is vfo output. B is output from the common i-f, and C is bfo output. Pad D is input to the filter, while E connects 12 volts to the vfo from the other board's constant 12-volt supply connected to pads marked 12C.

Pads to accommodate a balancing capacitor if it should be needed as mentioned earlier are marked with small letters. One pair is a and b, the other c and d.

Pads marked 12R are for 12 volts applied during receive mode, and 12T designates a connection for 12 volts applied during transmit. Only one pad is needed; others are spares. There is a separate pad (12C) for the bfo, however, and it should be connected to a constant source of 12 volts along with one of the other 12C pads.

The pad marked TR is used to control the diode switches in the i-f strip. A 12-volt level is used for transmit and a ground level for receive. A TR relay would normally control this line as well as the 12R and 12T connections. The bfo crystals are similarly controlled by application of either 12 volts or ground to pad 10.

Of the other numbered pads, none needs individual explanation since the schematic clearly indicates their locations and the function becomes obvious.

Coils and Transformers

All the transformers are fabricated from regular 10-mm 455-kHz transistor i-f transformers. T1, T2, and T4 require the bare parts only, which means removing the tuning capacitor and all wire from the bobbin. Carefully salvage all the wire as it will be used to wind the new transformers.

The large winding goes on first and the link is then wound over the top. T1, T2, and T4 should be wound as per the table, making sure

the pinout is correct. Views are looking at the pin end or bottom of the assembly.

For T3, carefully break off the secondary leads where they enter the bobbin. This is the side with 2 pins. Unsolder the remaining wire from the pins and clean off excess solder. Since the new winding is center-tapped, you'll have to steal a pin from a spare assembly and push it into the existing hole in the base. The new link is bifilar wound over the top of the existing winding and connected as per the table. Identify the winding in some way so you won't have trouble orienting the transformer when mounting it on the board. The new winding goes to the CA3020 output.

The vfo tank coil, L1, is pie-wound on a slug-tuned PC coil form. I used a Gowanda series 7 Velvetork form which is .209" in diameter by .625" long. A carbonyl E (red) core was used for the slug. Impregnate the winding with hot coil wax and put a single turn link over the top of the pie for L2.

Construction

I doubt that there will be any mad rush to duplicate this rig exactly as it stands, but parts of it may be of interest to some readers. I even debated the need to supply PC layouts, but decided they might prove helpful in some way. Just in case you do wish to copy the layout as much as possible, the following information may be useful.

All resistors, diodes, and rf chokes were mounted hairpin fashion to conserve space. Miniature low-voltage ceramic capacitors were used for coupling and bypass applications. Polarized capacitors are dipped tantalum and resistors are ¼ Watt.

Before mounting the SG3402T used as the receiver mixer, cut off pin 6. Likewise cut off pin 4 of the product detector. The same goes for pin 11 on the CA3020.

The 2 trimmer capacitors in series with the bfo crystals are subminiature (5-mm) units in case you were wondering how they squeezed into the space allotted to them. Incidentally, the exact operating frequency for the crystals will depend on the particular filter used, but this circuit will pull quite a bit and allow appreciable leeway in crystal accuracy.

Note that there are 2 silver mica capacitors across the ends of the mechanical filter whose purpose it is to tune the two transducer coils. Values will depend on the type of filter used. For the F455 Q2 that I used, I had to install a 91-pF capacitor at one end and a 110-pF capacitor at the other end.

The 3-gang tuning capacitor is the same one used in the Minicom receivers and has a range of approximately 3 to 20 pF per section. An additional padding capacitor is required across each of the first 2 gangs. Use 20- to 22-pF silver micas and solder directly to the frame before installation. When mounting this item, use #4-40 screws ¼" long. Put a toothed washer under the head to allow good contact with the copper. Place 2 flat washers over each screw on the component side before mounting the capacitor. This will leave enough space to clear the rivets that hold the compression trimmers for the first 2 gangs.

I used MPN3401 (Motorola) diodes to do the switching since they were in my junk box and are made especially for this use. Regular silicon diodes should work okay, so don't panic. No other remarks come to mind regarding components, so I'll get on with the checkout.

Tune-Up and Checkout

A DPDT toggle switch can be used for TR switching by using one section to apply 0 or 12 volts to the

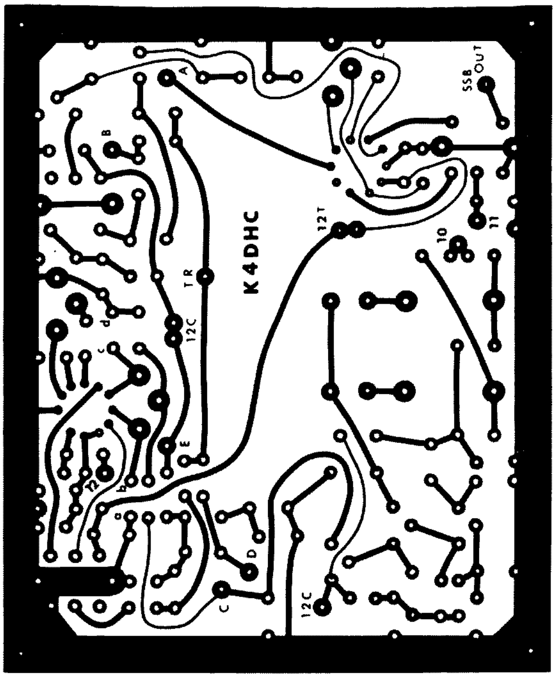

Fig. 3. PC board for transmitter.

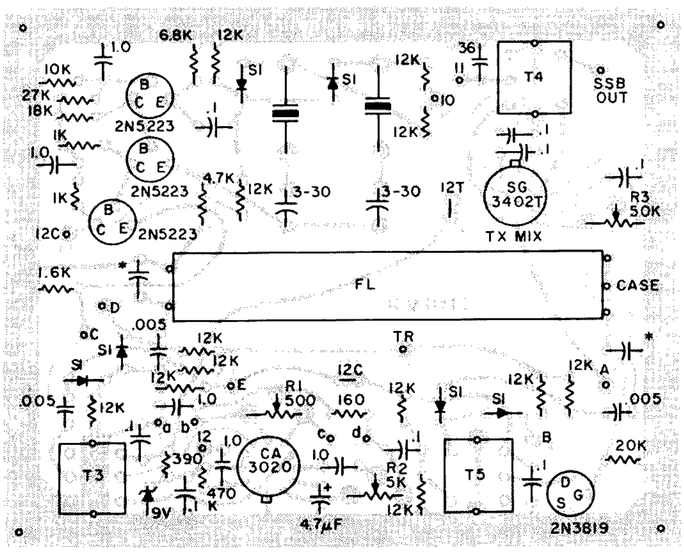

Fig. 4. Component layout for transmitter board.

TR line and the other half to transfer 12 volts between the receive and transmit circuits. An SPDT toggle can be used to switch the bfo crystals. A 10k audio gain control with log taper and a 10k rf gain control with linear taper are the only other items needed at this time. With the boards lying on the bench, make the jumpers between boards long enough so that each board can be handled freely while making adjustments. The copper border around each PC is ground and should be made common with all other grounds and power-supply return.

Connect an 8-Ohm speaker and 12-volt power supply to the rig. Set all trimmers to midpoint. Run the screws on the 2 compression trimmers on the 3-gang capacitor up snug but not tight. Turn the variable to full mesh. Connect a dc scope or high-impedance voltmeter between the top of the rf gain control pot and ground. Switch to receive and apply power. Current drain should be between 55 and 65 mils. Turn the rf gain control all the way down and adjust R4 for a reading of 6 volts. Disconnect the meter and turn the rf gain to maximum. Turn up the audio gain and feed in some signal at 3.5 MHz. Adjust the slug in the vfo tank coil until the signal is picked up. Adjust the cores in T1 and T2 for maximum output. Run the variable capacitor up to the high end and feed in signal at 4.0 MHz. Peak the response by means of the 2 compression trimmers on gangs 1 and 2. Repeat these 2 procedures as many times as needed to achieve good tracking. T5 can be peaked on the noise present. If the band is active, you can connect an antenna and listen on the air to verify proper operation of the receiver. Also make sure both bfo crystals are working. This concludes receiver checkout.

An audio generator should be connected to the mike input during tune-up of the transmitter. Turn R2 to minimum and switch to transmit mode. Current drain should be 40 to 50 mils. Connect a scope to the output side of T3. A piece of discarded pigtail can be temporarily soldered to the pad if necessary to make the scope connections. With no audio input, adjust R1 to null out the carrier. If there is still some trace of rf, tack a mica trimmer across pads a and b and then c and d to see where improvement can be made. Measure the value of the trimmer at the best setting and substitute a silver mica fixed capacitor.

Once the carrier has been nulled, turn up R2 and feed in some audio signal at around 1500 Hz. Adjust the level to a point just below where distortion occurs as observed on the scope. Transfer the scope to the output side of T5. Determine the values for the capacitors that tune the filter and install them at this time. Turn the tuning capacitor up to the high end of the band just below 4.0 MHz and transfer the scope to the transmitter output at T4. Shut off the signal generator and null the vfo signal by adjusting R3. Turn on the generator and adjust the core in T4 for maximum output. Later on, a tuning capacitor can be mounted on the front panel to allow peaking of the output as frequency is changed. That concludes tune-up of the transmitter.

I've listened to the signal from this little rig on some of my Minicoms and can report that it sounds excellent.

If you write, please remember to enclose an SASE if you expect an answer. ■

In Quest of Perfect Break-In

—well . . . almost perfect

PROLOGUE: About twenty years ago—no, more—it was the year the Russians blew our minds and our national ego by putting up their *Sputnik 1*—I found an article in an encyclopedia in the library at my high school.[1] The essence of the piece was that just anybody could have his own private radio station and communicate with other anybodies who had *their* own private radio stations. It gave detailed instructions for building a one-tube receiver. It hinted at a simple transmitter and even let on that one should get a license before transmitting.

I sent off for a hundred-pound grab-box of electronic goodies. I used only one thing: a filament transformer to heat the single filament of that single tube in my first home-brew receiver. I wound one of the coils a few turns too much (using a cardboard core from a roll of paper towels), and, behold! The local broadcast stations could be tuned in. A veritable miracle on a masonite frame.

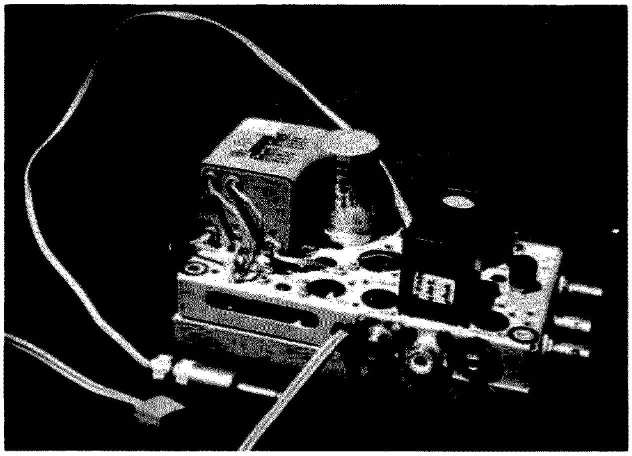
Next, from another article, I built a simple transmitter. No, I didn't get the license, and I didn't even learn the code. But I didn't break the law, either, although I intended to. This little widow-maker, I later learned, was high-voltage keyed. When I fired it up, it knocked me across the room as soon as I touched the key. I took it apart and let my yen for a personal radio communications station cool for fifteen or twenty years.

After I got out of the Army,[2] the yen returned. My wife drilled me in the code without ever learning it herself. I bought the first commercially-manufactured amateur transmitter I had ever seen or heard of: an Eico Model 720, for $25.

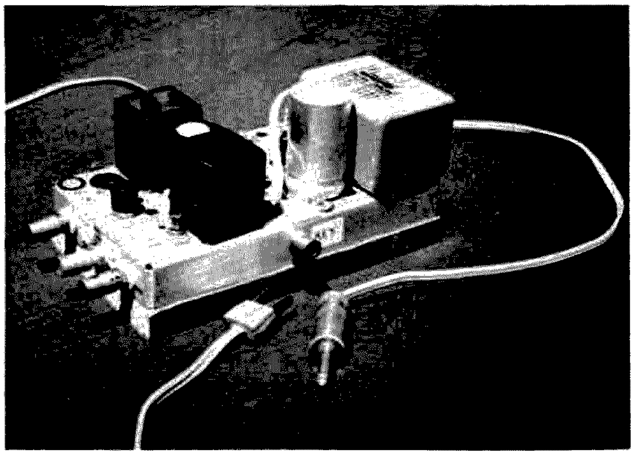
"What will they think of next?" I asked myself. "Somebody is saving us new amateurs a lot of trouble by building our transmitters for us."

That little jewel didn't work and it didn't have a manual or a schematic, and I didn't have a license yet, but I went right out and bought a nice brass key and a pair of coax connectors. A few days later I laid out thirty-five dollars for an Army surplus BC-348-Q receiver at a local swap meet. (Not a hamfest. I hadn't even heard of such a thing.)

WA7UKB was my "Elmer," my encourager,



This is the finished QSK unit, showing antenna jacks, ugly holes, and wooden base.



The finished QSK unit from its good side, showing mute adjustment, mute-defeat switch (the push-button), and mute and sidetone binding posts.

my teacher. I became WN7CMZ. I was legal. I could transmit. At last. And with such modern, up-to-date, ready-made equipment as I could not have imagined to exist a short time before.

Look out, world! WN7CMZ is about to transmit! Plug in the crystal. Fill out the logbook headings. Warm up the tubes. Transfabulate the franistan. Borrow W7KWJ's swr meter. Prune the dipole to the last half inch. Pull up a chair. Throw the knife switch to "receive." Listen. Throw the knife switch back to "transmit." 4 . . . 3 . . . 2 . . . 1 . . . TRANSMIT!!

YEEOOUUP YIP YAARRK YIP—WOOOP YEAAAP YIP WAAAZHP . . .

"Mercy sakes, good buddy! My nice new receiver has gone to the happy hunting ground." It hadn't. When I threw the antenna switch back to "receive," the WWII surplus receiver made those beautiful sea-double-you sounds again.

I asked a lot of questions and listened to a lot of answers and bought a book about amateur radio and studied it. I built an electronic transmit-receive switch right inside the transmitter and thought I was the only ham in the world smart enough to do this, seeing that my cookbook-type instruction sheet showed it on a separate chassis with a separate power supply.

I bought another receiver. It was bigger and prettier than the BC-348, but it had no markings at all, so I could never tell anyone just what I had. Anyway, with this handy combination I could transmit by pushing the key down and listen by letting it up again. The receiver overloaded very nicely and merely woofed and grunted when I transmitted, and I actually made a few contacts—some of them out-of-state.

The next summer I found out about hamfests, and I went to the one at Flagstaff. I bought a Johnson Viking Ranger because it had a built-in vfo. This transmitter didn't work, either, but it had a manual and schematic. In fact, it had two manuals—both for the Ranger II. I took out the modulator and built in a T-R switch just like the other T-R switch. It didn't work quite like the other. In fact, it didn't work at all. I built two or three different kinds, following magazine articles and friendly advice. They didn't work either.

Back to the old knife switch. Back to turning the receiver gain way down to transmit and turning it back up again to receive. Back to lost QSOs.

Back to reading about ham instead of doing ham. I bought a big pile of *73*s and other amateur magazines second-hand and spent a lot of time reading them.[3] There are a lot of articles in the back issues that are worth reading. Some of them tell how to change from transmit to receive without having to throw half a dozen switches. Some of them tell how to do it without using noisy, old-fashioned relays. I laid out about a day's wages for PNP transistors in blister packs and proceeded to gather the other components. The day before the transistors came in the mail, I finally found what I was looking for all along: How to do it *with* those noisy, old-fashioned relays.

Now, I had never lost the love of surprises ever since that hundred-pound grab-box twenty years before, and sometime along then I started buying two-ton grab-piles from Department of Defense Surplus Sales.[4] Therefore, I had a very respectable junk box. It's about four feet deep in not-so-neat rows all across my back yard. There are lots and lots of noisy, old-fashioned relays in MY junk box.

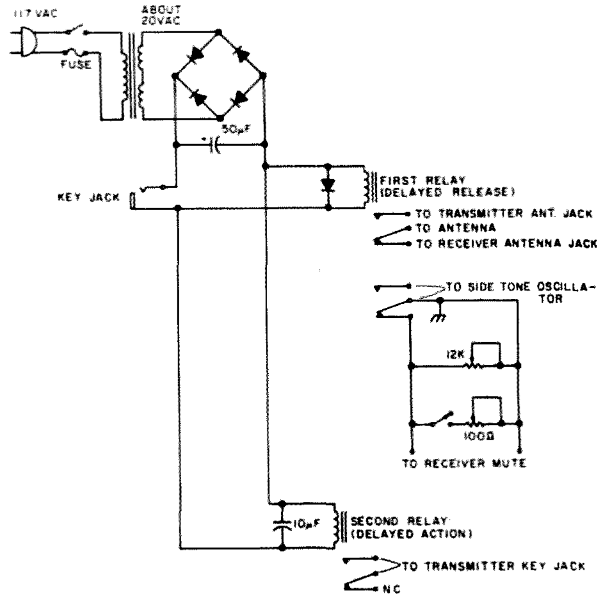


Fig. 1. Schematic diagram of break-in unit. The diode across the first relay delays its release; the capacitor across the second relay delays its action. Parts values are not critical. Contacts are shown with relays not energized.

It seems the problem with relays is that the contacts cannot handle nearly as much current when they are opening and closing as when they are already closed. Sparks fly. Metal melts, or even vaporizes. The contacts get rough, pitted, oxidized, non-conductive. They may even weld themselves together. But if the current does not flow except while the contacts stay closed, those nasty things don't happen. (Unless, of course, you have a *lot* of current flowing.)

If you key the energizing coil of a DPDT relay and have one set of contacts key the transmitter and the other set change the antenna over from the receiver to the transmitter, pretty soon you fry the antenna change-over contacts because the finals are still putting out when the antenna connection opens at the end of each dit or dah. Sparks fly, etc.

You really need two relays set to operate a very small fraction of a second apart. When you close the key, the first relay should change the antenna from receive to transmit and *then* the second relay should key the transmitter. When you open the key, the second relay should unkey the transmitter and *then* the first relay should change the antenna from transmit to receive. This way, there is no rf flowing in the relay contacts while they are opening and closing.

Here is the precious secret the Guru up on the high mountain peak in Northern India imparted to me, and now I disclose it to the world. (Actually, it has been disclosed to the world many times before, in amateur radio magazines, engineering texts, electronics magazines, the *Toymakers Journal*, handbooks, letters to the editor, over the air, and under the counter.)

You can *delay the opening* of a relay by putting a diode across the coil so that the inductive 'kick' when the current is shut off has a place to go; it goes

through the diode and back around the coil, and around and around it goes until it gets tired of going around and just lies down and quits due to the resistance of the circuit. This holds the relay closed a long time—maybe a thousandth of a second. When it finally, at long last, opens, a millisecond or so later, one hopes that there is no current left at the contacts to burn them up and weld them together. If your relay opens too slowly to suit your purpose, put in a few Ohms of resistance.

You can *delay the closing* of a relay by putting a capacitor across the energizing coil. When the current comes to close the relay, it has to charge the capacitor to a certain extent before it can close the relay. The delay is controlled by the capacity. This delay lets the other relay close and change the antenna over to "transmit" before the transmitter is even keyed. (See Fig. 1.)

This is not a secret, not a new breakthrough. But it was new to me. And very interesting. I went looking through my rows of surplus electronic scrap.

There was an aluminum chassis, about the right size, and it took me only half an evening to get the goverment parts off it so that I could put my parts on it. There were the relays, of course, and a filament transformer with enough winding to put in series to get enough volts. There was a solid-state rectifier bridge, a diode, and lotsa connectors. No two parts came off any one chassis in my junkyard; oops, pardon me. I mean junk box. Never bought a thing for this project.

Well, yes, it looks kinda funny, and there are holes in the chassis with no parts in them and circuit labels for circuits that aren't there any more. The labels that count are just stick-ons, and there's that big capacitor that's merely taped onto the side of a relay. There's no panel, and wires stick out of every side except the bottom. But it works. And I did it my way. No one else ever had a QSK unit just like this one.

You're smart. You're careful. You can make a better, prettier one.

About those noisy, old-fashioned relays: They clack, clack, clack. Transistors don't. When my super-stable antique transmitter vfo drifts so far that I cannot hear my own sending on my super-stable antique receiver, I can still hear my sending, after a limited fashion, in the clacking of the relays.

These good government relays have extra sets of contacts and they are useful, too. Hook up one set as a mute and sidetone control. (See Fig. 1.) This thing worked the first time around. (That should prove there is nothing critical about it.) The receiver was silent when the transmitter was keyed, and it came back to life instantly when the key was raised. I actually made a contact or two that way before I tore into it to make improvements.

In order to hear the signal on the receiver, it cannot be altogether muted. (That's because I never got around to building that sidetone oscillator.) The diagram shows a variable resistor across the receiver-mute contacts of the first relay.[5] It is there to adjust the loudness of the transmitter as heard in the receiver. Now I could hear myself send, but could not zero-beat the transmitter to the incoming signal without sending out a full-strength signal. It is a "no-no" to twiddle the vfo dial around with the finals turned on. It aggravates a lot of people to hear that horrid WAH-YOOP sound when they are copying code, especially when they're copying the DX ham's callsign. The last thing I've done (so far) to this thingie is to add the "spot" switch and a second variable resistor across the receiver-mute contacts of the first relay.[5] By closing that switch, I can hear the transmitter vfo and zero-beat the guy who's calling CQ before turning on the finals. By opening it, I can hear myself send without ripping my speaker cone and my eardrums. And the relays take care of changing the antenna from the transmitter to the receiver and back and turning the gain up and down as fast as I can key.

No. I haven't achieved Nirvana. Pardon me, I mean perfect break-in. But I have had many relaxed, satisfactory communications since I built this thing. Now that I write this, it occurs to me that it is too complicated, too ugly . . . maybe a single relay would do—an open frame relay where I could get at the contacts and just bend them a little so that one contact makes before another. Let's see, a triple-pole, double-throw relay . . . and build it right into the transmitter . . . quiet it with sponge rubber, maybe . . . hmmm . . .

I can see now that this is not the final chapter of "Quest." In fact, it is *all* prologue. ■

The Amazing Audio Elixir

—this limiting amp is a cure-all

Back in the days of the Old West, there were groups of traveling salesmen who sold snake oil and other cure-alls. The claims made by these people and their medicine shows were that if you bought this wonder elixir, it would cure anything that ailed you. Here is a modern-day electronic circuit which will "cure all that ails you." The circuit presented here is a general-purpose amplifier which can be used to solve many problems and increase the performance of many audio circuits. The unique feature of this amplifier is that it will take an input of 100 mV to 10 V while the output level stays the same. The output is adjustable from no output up to about 8 volts peak-to-peak. You are, no doubt, asking what it is used for. Let me describe a few uses which will get your mind working and then you can take it from there.

In a repeater system, a tone decoder is used for control. The tone decoder works best with some precise input level, and the users are always tweaking the pad levels to make their pads work the system reliably. Drop an audio limiting amplifier between the receiver and the tone decoder and the problem is gone. Another use is in an autopatch system. Put one of these little units between the phone line and the transmitter and you will always be able to hear the person on the phone at the normal level.

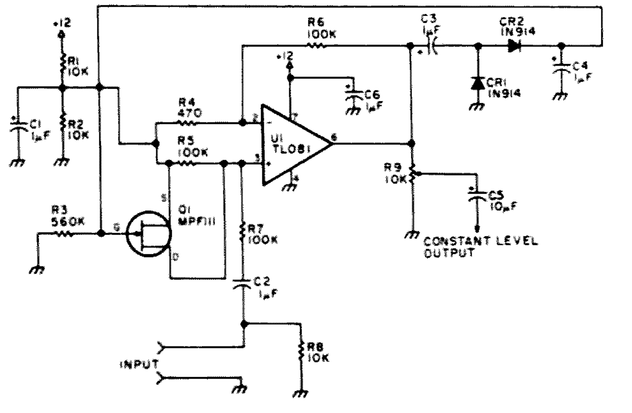

Fig. 1. Audio-limiting amplifier diagram. (This diagram is supplied with printed circuit boards.)

For you computer buffs, take this unit and put it between the output of the tape recorder and the tone input to your interface unit and get constant levels even as the tapes age. My 2-meter SSB rig does not have agc in it. When I have the volume high enough to hear a DX station and a local comes on, the level change inverts my speaker cone and my chair (with me in it). I lifted the wire from the top of the volume control and placed one of these units between it and the volume control. Now all the stations come out at the same level, at whatever level the volume control is set, and there is no more ear damage for me.

I know of one person who set up a room microphone and used this unit to record anyone talking in the room without moving the microphone or having to ride the tape recorder's input control. With touchtone™-type signals, place a group splitting filter in front of two of these units and independently level each tone group to remove any twist or imbalance in the tones. How about a speech processor? Use this unit in a fast-agc mode and drive the input to your SSB rig at full level all the time. Another use might be as a "linear clipper" in a modulator. Drive the unit below the point where the output limits, and if the signal through it gets too high, the limiter cuts back and won't allow excess audio to pass. The advantage of this unit over normal clipping methods Is that this unit does not clip, and thus it does not add clipping distortion. Enough of these ideas. Let's go on to see how it works.

How It Works

See Fig. 1. U1 is an op amp and is simply a gain block. The gain of U1 is set by the values of R4 and R6. As shown, the amplifier is set for a gain of about 200. The output is sampled by C3, CR1, CR2, and C4. This network produces a dc voltage directly related to the ac (audio) output of the amplifier. This dc level is fed to the gate of FET Q1, which is an inexpensive Motorola MPF111. This FET is not critical and any

equivalent FET will do. R1 and R2 form a voltage divider which is used to bias the FET source and the op amp inputs at a point exactly one-half way between the power supply voltage and ground. C1 ensures that the bias point is at ac ground. With no detected voltage from C4 to the gate of Q1, the gate of Q1 is at ground, which is negative to the source, and the FET is in a "pinched-off," or nonconducting, condition.

The incoming signal comes in through R7 and is amplified by U1. The output is detected and the dc voltage is fed back, which lifts the gate of Q1 from ground and Q1 starts to conduct. As Q1 conducts more and more, it shunts the input signal away from the op amp input. R7 and R5 act as a voltage divider and, with the FET, R5 acts as a variable resistor. The combination acts as an electronically-operated pot, with the "wiper" connected to the input of the amplifier. Once the detected output reaches a certain level, it will cut back the input signal and not allow the output to go any higher.

The purpose of C2 is to block the bias voltage from going out the input. R8 is used only to terminate the input and should be a value that the driving circuit wants to see. It can be any value because it has no effect on the operation of the circuit. Since U1 is a closed-loop amplifier with a fixed gain, the output will drive anything as long as the output capabilities of the op amp are not exceeded. Even though there is some circuit loading, I have even driven small speakers with this unit and obtained output volume which was usable for testing purposes. The amplifier is protected so you do not need to worry about damage.

This unit is designed for 12-volt operation, which is near its lower operating voltage limits. The voltage is not critical, and as long as the voltage limits of the capacitors are not exceeded, it will work over a wide range of voltage. The lower limit is 12 volts and the upper limit is greater than 30 volts. If different agc release times are desired, the value of R3 may be changed. The larger the value of R3, the longer, or slower, the recovery time of the amplifier. When used as an agc, it has a fast attack time and a fast decay with the values shown.

In conclusion, this article was meant to be mostly an idea article and describes a building block which I have found to be very useful. Circuit boards may be obtained from the author for $3.50 each and are top-quality glass-filled, drilled boards with silk-screened parts layouts on the surface. ■

Parts List

Designation	Description	Qty.
U1	TL081 BiFET op amp	1
Q1	MPF111 FET	1
CR1, CR2	1N914 signal diode	2
R4	470-Ohm, ¼-Watt, 5% resistor	1
R1, R2, R8	10k, ¼-Watt, 5% resistor	3
R5, R6, R7	100k, ¼-Watt, 5% resistor	3
R3	560k, ¼-Watt, 5% resistor	1
R9	10k pot, multi-turn variable resistor	1
C2	.1-uF mylar™ capacitor	1
C1, C3, C4, C6	1-uF electrolytic capacitor	4
C5	10-uF electrolytic capacitor	1
	PCB	1

No More Rotary Switches!

—gadget freaks will love these solid-state replacements

D. N. Ellis WA2FPT
R. D. 1, Box 108A
Ulster Park NY 12487

Are your bored with rotary switches in your projects? Even if by some slim chance you are not, here are a few simple remedies for replacing those tiresome rotaries with a sequentially-stepping counter that lights one of a string of LEDs each time a pushbutton momentary switch is pushed.

The cost of such a system is about as much as you would pay for a new rotary switch, but the main attraction is that it makes that "electronic wombat finder" of yours a real eye-catcher that is fun to use.

The devices described here are primarily CMOS, because I am a devoted CMOS fanatic. With proper attention to the pertinent peculiarities, however, any other logic family will work well.

A two-position, two-deck rotary switch eliminator is shown in Fig. 1. The switch portion of the circuit is a set-reset flip-flop that gives clean, bounceless low-to-high transitions to clock the counter. The counter is a 4013 D-type flip-flop wired as a toggle. It divides the incoming clock frequency by two and transfers data from the D input to the Q output on the positive edge of the clock pulse. Each push of the button puts a low to high signal at the clock input. With CMOS, these levels are essentially ground and the supply voltage. We will call these low and high levels "0" and "1" for clarity.

The characteristics of a D-type flip-flop wired as a toggle, with the $\overline{Q}_1$ output fed back into the D input, is that for every 0 to 1 transition on the clock input, the Q output changes, and then remains at that value until the next positive going clock pulse comes along. This means that it has two stable conditions. If the Q output was at a 1 level, then a single push of the button would change it to a 0. The next push would send it back to a 1. The $\overline{Q}$ output does the same, but, of course, is of the opposite polarity.

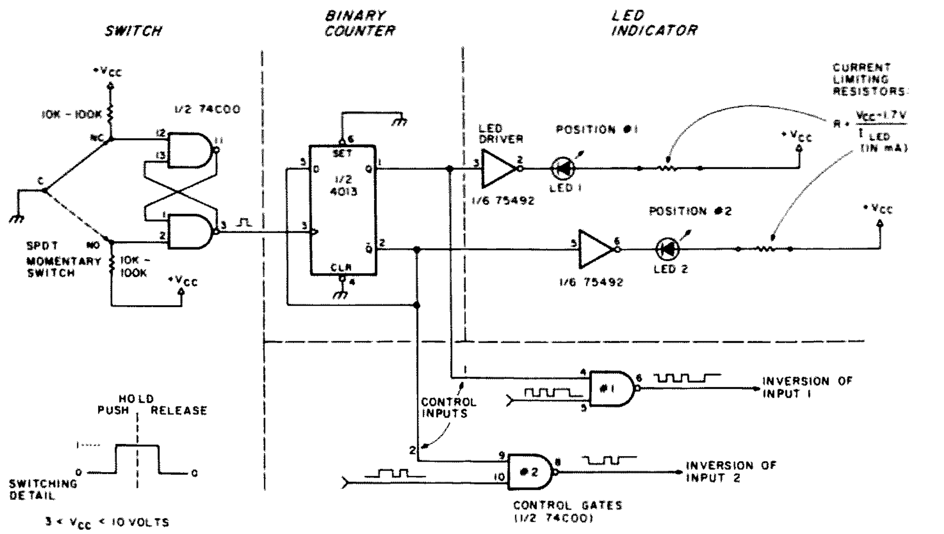

Fig. 1. Two-position rotary switch eliminator.

As each of these outputs assumes a 1 level, it will turn on its LED driver, the 75492. The 75492, which has six drivers per package, is a power amplifier to supply the current requirements of the LED. The LEDs current is limited by a resistor whose value will be determined by the supply voltage and the desired current. A reasonable formula for such calculations is given in Fig. 1.

Speaking of power, CMOS works fine on 3-15 volts, but the 75492, a bipolar device with CMOS compatible inputs, is limited to 10 volts. Anyway, whichever one of the outputs, Q or $\overline{Q}$, is at a 1 level will cause the 75492 driver

to go low, which will forward bias the LED, turning it on.

So much for the indicator, but what will it indicate? We need our switch to control something. This is accomplished by the remaining 74C00 2-input NAND gates labeled Control Gates. This section of the circuit is the second "deck" of our two-deck switch eliminator.

A 1 from either the Q or $\overline{Q}$ flip-flop at one input of the 74C00 will allow an inverted replica of a signal at the other input to pass through the device. A 0 at the control input will keep the output at a 1 level regardless of the condition at the other input. As the button is pushed again, the control is shifted to Control Gate 2 and Control Gate 1 is disabled, remaining at a 1 level.

Because of the binary nature of toggle flip-flops, any number of switch positions that is a power of two can be readily made by cascading these binary dividers until the desired number of stages is reached.[1]

A four-position rotary switch eliminator is shown in Fig. 2. With these two flip-flops come a possible four combinations of the Q outputs, Q_A and Q_B. They are 0,0; 1,0; 0,1; 1,1. The next sequences are only repetitions of the first. The sequence is as follows: Assume both Q_A and Q_B are at a 0 level. After the button is pushed once, Q_A goes to a 1, but Q_B is still at a 0 level. So far the count sequence is 0,0; 1,0. The next push gives a 0 at Q_A, but now Q_B goes to a 1. The sequence is now 0,0; 1,0; 0,1. The third push of the button flips Q_A to a 1, but because Q_B changes only half as often, it remains a 1. The sequence is now complete: 0,0; 1,0; 0,1; 1,1. The next push would cause Q_A and Q_B to become 0,1.

Now we have to decode

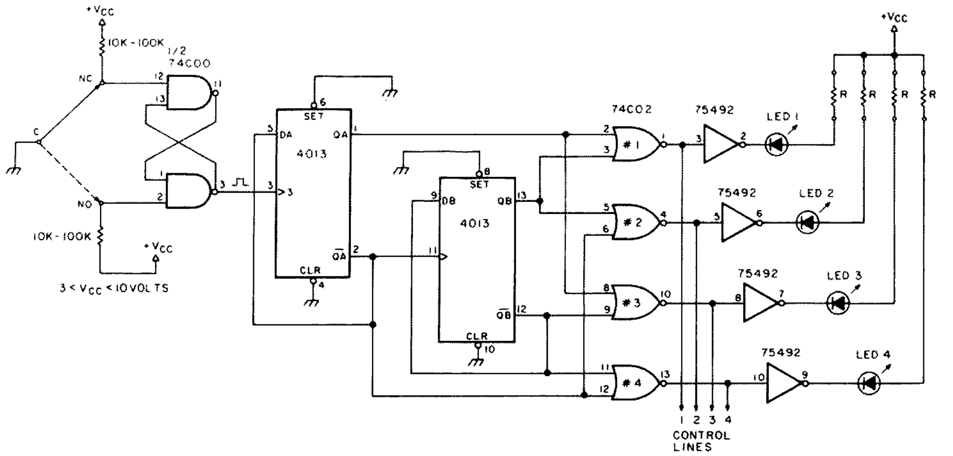

Fig. 2. Four-position rotary switch eliminator.

each of these pairs of outputs to light four LEDs in sequence, one at a time. The 74C02 quad 2-input NOR gates do this trick neatly.

The NOR gate is a great "zero detector" because it will give a 1 output only when all of its inputs are at a 0 level. The NOR gate fed directly with Q_A and Q_B would output a 1 level only when the count of 0,0 was reached, turning on the 75492 LED driver, illuminating LED 1. The next state in the count sequence is 1,0. This will extinguish LED 1 because the 74C02 no longer has the conditions required to turn on LED 1.

For LED 2 to turn on, we can use Q_B directly because it is a 0 level. Instead of Q_A, though, we'll use $\overline{Q}_A$, which is a 0 when Q_A is a 1. Now 74C02 #2 has the proper zeros on the inputs to give a 1 output to turn on LED #2. The next state of the counter results in a Q_A of 0 and a Q_B equal to a 1 level. 74C02 #3 will be activated by using Q_A and $\overline{Q}_B$, the exact opposite from the requirements for 74C02 #2.

The final push gives a 1,1 condition, which needs both $\overline{Q}_A$ and $\overline{Q}_B$ to be used as 0 inputs to 74C02 #4 to turn on LED #4.

So much for a four-position switch, but how about an odd number like three? What we'll do is to start with a four-position switch and use the fourth state of 1,1 to reset the circuit back to 0,0. The counter will think it is still a four-position counter, and only we will know the difference.

The three-position rotary switch eliminator is shown in Fig. 3. The significant difference between it and the four-position counter in Fig. 2 is that the 74C02 #4, which detects and decodes the 1,1 condition, is used to reset both halves of the 4013 to zero, giving a count sequence of 0,0; 1,0; 0,1, and back to 0,0.

The point of this decoding business is to ensure that each and every combination of counter outputs results in only one LED on at a time. Otherwise, we will have the equivalent of a rotary switch with shorted contacts.

If you are interested in readable, useful information on counters, try one or more of Don Lancaster's *Cookbooks*. The "reci-

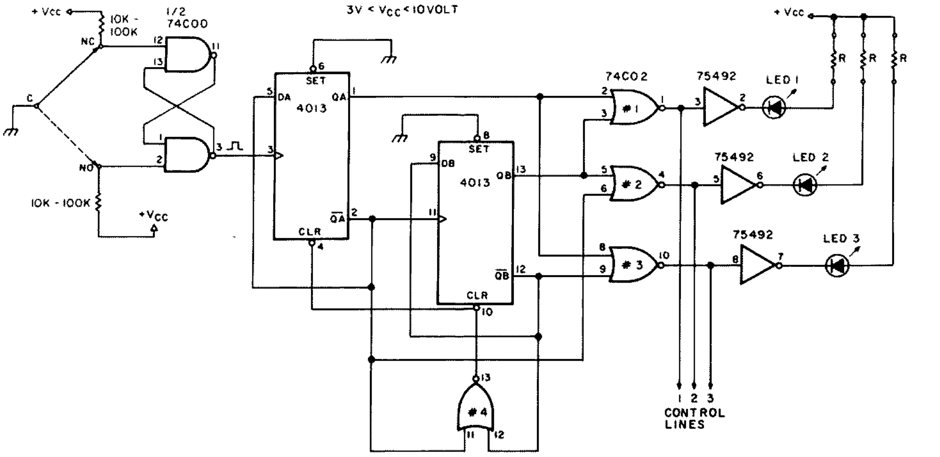

Fig. 3. Three-position rotary switch eliminator.

pes" satisfy most digital appetites without overstuffing.[2]

Simulating any number of switch positions is possible by remembering two basic guides. One is to be certain of the *sequence of the outputs of the flip-flops* as you push the button. This knowledge will allow you to properly decode the outputs to control the LED lighting and whatever else you have in mind. Equally important is to be sure that *all the output combinations are accounted for*, either for proper decoding, or for resetting the counters, as shown in the three-position counter. Any combination you miss will at best give the effect of a dead switch position, or, as previously mentioned, a shorted switch.[3]

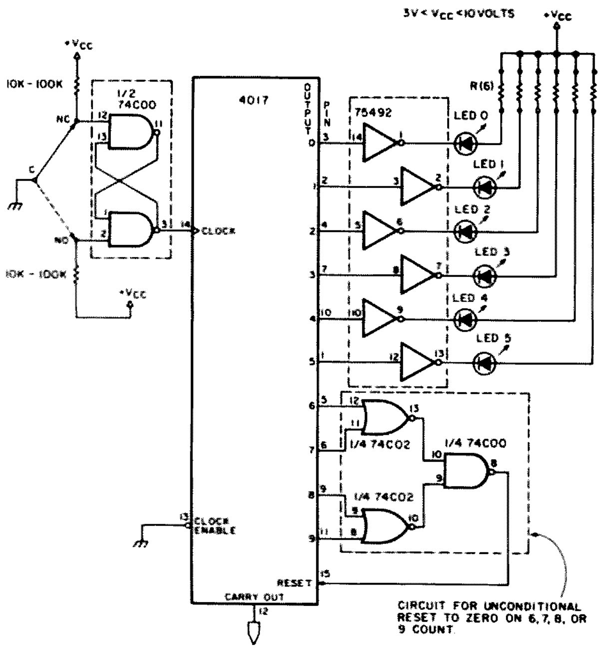

Fig. 4. Six-position rotary switch eliminator using a 4017 decade counter.

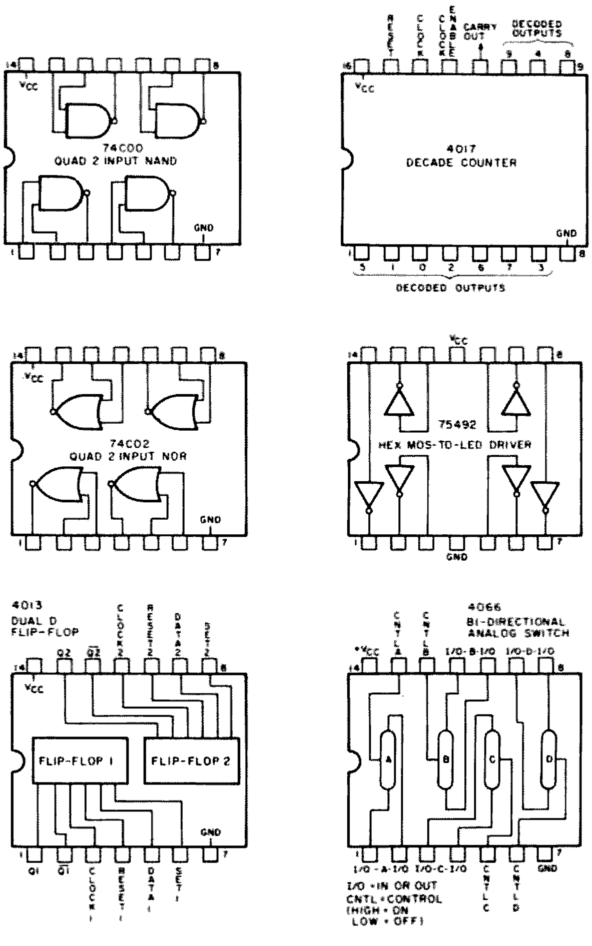

Fig. 5. Pinouts of the ICs used (top view).

An easy way to avoid concerning yourself with much of the above trouble is to use a resettable counter like a 4017. Any number of switch postions from 1 to 10 can directly be implemented. The 4017 is a five-stage divide-by-ten Johnson counter with ten unique decoded outputs. Johnson must have been clairvoyant, because this sixteen-pin package is just what we need.

The example in Fig. 4 is a six-position rotary switch eliminator. This circuit will count from 0 to 5, then start over again with successive pushes of the button. The two 74C02 gates and the 74C00 gates eliminate any hazard of unwanted outputs, in this case, a 6, 7, 8, or 9 count. You'll recall that the NOR gate gives a 1 output if all inputs are 0. Well, any active 6, 7, 8, or 9 output will give a 0 at the output of the one of the NORs, and this 0 will drive the 74C00 NAND's output to a 1 level, which will just happen to reset the counter to 0. Now at any count from 0 to 5 the 6, 7, 8, and 9 outputs are all 0. Following these through the NOR and NAND logic gives a 0 on the reset line, which is just what we want, that is, no reset until a 6, 7, 8, or 9 appears. The 0 through 5 outputs control the lighting of their respective LEDs through the six gates of 75492 package. These lines can also be used to control other functions, as in Fig. 1. Easy enough. The 4017 also has a carry out, which allows cascading 4017s together for long count sequences. More components, a little imagination and a calloused index finger are the only requirements.

So far, only digital controls have been discussed. By using 4066 bi-directional analog transmission gates, low level analog (or digital) signals up to 40 MHz can be faithfully controlled with minute distortion. Just substitute 4066s for the 74C00 Control Gates as in Fig. 1. Pinouts for all the devices mentioned are shown for reference in Fig. 5.[4,5]

As an extra attraction, these circuits also have built-in service aids. The LED indicators can act as diagnostic pointers by "illuminating" your logic and/or wiring errors. With all this in mind, "switch" to these rotary eliminators for your current and future projects. If you have the capacity, I'm sure you'll get a charge from designing and building them. You, too, can be the envy of friends and rivals alike! If I have etched them into your memory, then they will certainly be difficult to resist. ■

Confessions of a Teenage HFer

—the world between channel 40 and 28 MHz

"Breaker, lawbreaker!"

Hans Peter
c/o 73 Magazine

In August of 1975, while I was a long-term patient in the hospital, I received an AM mobile transceiver. This was before the FCC changed the Part 95 regulations to allow idle chitchat one month later. I did not receive my FCC call letters until October, two months later, but of course I transmitted before then.

Roll Your Own

On all crystal-synthesized 23-channel CB rigs, there was a blank spot between channels 22 and 23. It was normally an inoperable channel that, I thought at the time, was the position to use when using the PA function. After meeting a few other CBers and discussing equipment, I learned that on a few rigs, by setting the dial between the blank spot and channel 23, it was possible to "roll in" a non-CB channel, commonly called 22A. There was also another channel called 22B, but this channel could only be installed by adding at least one crystal to the rig. No one really knew what these channels were for, but supposedly they were business channels.

I could not roll this channel in on my particular rig, so I wired in 2 switches to connect where the rotary switch was not making contact. It worked, and I was very excited to discover this modification. It seemed that most people thought that if you could not roll it in, then it was not possible to get this channel. At that time it was a quiet channel and at first only a few "elite CBers" had it.

I did read in an advertisement for an 11 meter vfo that 22A and B were for business traffic, but I never did hear any, and I could not find anything about this in FCC rules and regulations.

I also started modifying other CBers' radios to get this channel. It could be done by cutting a ground wire, or adding a jumper wire, or installing a toggle switch if the manufacturer had gone to great lengths to internally defeat this channel. I charged five dollars to do this modification, although I knew of someone else with a First Class license who charged twenty dollars.

When people would get on frequency, they generally would say "break A" or "break 22A." Now this frequency has become channel 24. If you hear someone on the air saying "break A," they probably are using a 23-channel transceiver.

I met another fellow on 22A who was also interested in the electronic aspect of CB, and we became good friends. We both learned as much as we could about radio modification. We also did radio work for other CBers.

Moving Up

I eventually moved on to bigger and better things, namely getting into the HF aspect of 11 meters.

I studied my crystal synthesizer and eventually figured out that by changing two master crystals I would get 23 channels just above the class D channels. At first I had no idea where to get these crystals made. Finally, in a CB catalogue, I saw I could order crystal certificates and have the crystals made. I thought perhaps the company I sent the certificates to would not grind the crystals for me because they would result in out-of-band operations, but this did not happen.

After about 3 months of waiting, the crystals arrived. I thought that by just unplugging the original master crystals and plugging in the new ones, I would be all set. However, only the transmitter would work. The receiver was dead. I eventually found out I had to retune the synthesizer cans for each set of master crystals. But it did work and I got HF capabilities. Later, I tuned the receiver for a happy medium so both sets of crystals worked, but the receiver performance suffered and I got all kinds of receiver images.

CB shops eventually

started selling HF synthesizer crystals. These would give 4 or 5 new channels per crystal. They were hot items and sold out quickly. Very few CBers even knew how to wire in these crystals, and here I was of service. The crystals sold for five dollars. I would install a 2-pole toggle switch with one empty socket and an HF crystal for twenty dollars.

Gadgets

CBers are almost helpless when it comes to doing even simple modifications or repairs. Even when a microphone cord needs to be resoldered or a CBer buys a preamplified mike, he has to pay someone to fix or install it. This lack of technical knowledge leaves CBers open to many rip-off artists. I have seen standing-wave meters advertised as 40-channel standing-wave meters, as if the ones manufactured during the days of the 23-channel sets were inferior.

I have seen an item called a crystal vfo. What is it? It's a little box with a twelve-position rotary switch connected to twelve crystal sockets with a trimmer cap for each socket. Theoretically, one of these could give a crystal-synthesized transceiver 60 new channels. All this for only $100, less the crystals.

Other items in demand are tweety birds and pingers. The pinger produces a short feedback-like squeal of short duration when the microphone is keyed. The Browning Golden Eagle had this built in. Because of pressure from the FCC, the new 40-channel Brownings do not have this feature. It can easily be added because the pinger is still in the radio but is not connected when the set comes from the factory. Pingers are now sold as add-on units by an independent firm for about $18. These can be attached to any radio.

The tweety bird produces a chirping sound. They are often used to attract attention, but can cause severe bleed-over on adjacent channels. Prices for tweety birds are around $15 to $20. There are full page ads for both of these noisemakers in CB magazines, even though they are prohibited by Part 95 of the FCC rules and regulations.

Regular tunable 11 meter vfos are made which plug into one of the crystal sockets in the transceiver's synthesizer. There are two very popular models.

One, made by Siltronix, has a simple two-transistor LC circuit and is inclined to drift unless the unit is left on continuously. Few CBers know that these can be adapted to any transceiver by adding or subtracting some capacitance to or from the LC circuit. The other popular model is made by PAL. These are rather complex and use a crystal-controlled reference oscillator.

I have seen used units at hamfests going for $175 to $200, which is the same as the retail price. The funny part about eleven meter vfos is that in advertisements it specifically states that it is illegal to transmit with vfos, as if that will stop anyone. I charged $20 to install a vfo. I arranged it so the vfo could be disconnected from the transceiver, for obvious reasons.

The clarifier on a single sideband set could be modified into a quasi-vfo by changing some components or readjusting trimmer resistors. This increased the sliding range from ±500 Hz to about plus 2 kHz and minus about 13 or 14 kHz. Now the clarifier could slide into RC channels which are between class D channels.

In the world of CB, if something is illegal, it is even more desirable to have, and the CB consumer will pay an arm and a leg to have it.

Having a transmitter "peaked up" is another service in demand. Rarely can more than 1 extra Watt be squeezed out of an average CB transceiver and still have just a touch of upward modulation. Overdesign is not common. But a CBer usually thinks, "It may help me get out an extra mile." I usually charged $5 to peak the transmitter, but a licensed repairman could get $20 to $25. Of course, he had to do this under the counter. The big money in CB is in modification, not repair.

HF Lingo

How do HFers refer to illegal channels? They think of the frequency in megahertz and use the first three digits after the decimal point. So 27.415 would be just 415. This is the first channel above channel 40. From channel 26 through 40, the frequency can be determined by just adding a 5 to the end of these digits. Channel 40 is actually 27.405, channel 34 is 27.345. By extrapolation then, 27.505 would be channel 50. Many AM HFers use this method of nomenclature, and you will hear "Break channel 43" on 27.435.

Eleven meter single sideband is a rather new and very different development. Almost all CB sideband is on the lower side. Upper-side users are looked down upon and sometimes even harassed when on the air.

Sideband conversations are formalized. They are very similar to ham QSOs, which they are intended to mimic. No ten codes are used as on AM—only Q codes are used. There are no AM handles either; everyone uses first names. If you are an AMer new to sideband and have picked up the habit of saying 10-4, you will often be politely asked to try not to say it. "Roger" replaces 10-4 on sideband. There is very little of the stereotyped channel 19 lingo on sideband. But when skip starts, it is funny to hear sidebanders call out "CQ DX" over and over.

To replace handles, sideband operators have club call letters. The first CB sideband clubs formed used the number designating their state's place in the order of all states' admittance to the Union, followed by a W, which stands for World. For example, California would be a 31W state because it was the thirty-first state to be admitted to the Union. Newer clubs are using an N prefix, for National, so Georgia would be a 5N state. Other abbreviations include A for America and X for X-ray. It seems like the whole alphabet is being used.

An AM operator will generally get mad when someone else uses the same handle. Sidebanders will also get disturbed when someone else has the same club call letters. How can this happen? Well, 36A3536 could be the 36 Alpha or the 36 America club (Nevada) when written down on paper.

Many sidebanders get a number from every club in the area so they can use call letters to match the person on the other end of the QSO. The use of club letters makes a neater and more efficient operation on the crowded Citizens Band.

When the DX is in, it is easy to figure out what states other operators are in. Club call letters replace FCC call letters on the HF band. During local QSOs on class D frequencies, both FCC and club call letters are generally used.

An AMer might say, "This is the Hill Billy, KABC 1234, going 10-7 for the night."

A sidebander might say, "This is 36-National-1234, KXYZ 9876, QRT and QSY to bed."

Using Ham Gear

Most HF gear is modified CB gear with possibly a linear amplifier, but converted amateur gear is most popular among sidebanders. It may not be apparent, but amateur equipment has distinct advantages and actually makes sense. An amateur transceiver has a dynamite receiver. Its sensitivity and selectivity will beat any piece of CB equipment hands down.

Citizens Band is far more crowded than any ham band. In the evening, signals abound as people turn on their radios to have a conversation. Adjacent channel interference is unbelievable. Look around an average suburban area sometime, and see how many CB base station antennas are on the rooftops. Citizens Band has truly become radio communications for the people.

Before CB expanded to 40 channels, FCC type acceptance rules were very lax. Very inexpensive 23-channel transceivers were junk. Not only were they severe generators of TVI, but when a preamplified microphone was added, the transmitted signal was 15 or 20 kHz wide.

And think about this: The Cadillac of CB radios is the Browning Golden Eagle. This 40-channel set now retails for about $1000. A Drake or Yaesu has a transmitter that can be tuned and has complete range over the 11 meter band after relatively simple modification. The price is also several hundred dollars less. The cost of a moderately priced CB transceiver, external vfo, and linear amplifier is about the same as that of a piece of amateur gear.

Amateur transceivers put out a clean signal. There is very little spurious radiation and harmonic content. If everyone ran ham equipment on eleven meters, there would be virtually no TVI and far less adjacent channel interference.

There seems to be little interference to licensed users of the HF band, mainly because the business band is FM and usually 5 kHz off from most HF traffic. Business-band licenses are not being renewed because of expansion to 40 channels, and their signals are getting fewer all the time. There are a few business-band stations between the newly allocated CB channels, but few CBers realize what the buzz from the FM signal is. As far as government use of the HF band goes, it probably exists, but I have never heard any government transmissions.

Practically no one worries about being caught by the FCC. There may be a scare now and then that the FCC is in town, but I have yet to hear of someone I know being apprehended. With so many people into CB, it just cannot be controlled easily.

HFers are generally the CBers who go for ham tickets. After obtaining a ham ticket, they generally stop HFing or curtail their activity greatly. Getting a ham license fills their DX appetite and their HFing is done less and less after that. But most never leave CB for good because they still have too many friends there.

There are some CBers operating amateur gear who will not use a non-class D frequency. Most of these people are sidebanders. When CB had only 23 channels, only one of those channels came to be known as a sideband frequency. This was channel 16. As the popularity of CB began to rise, so did the crowding. Occasionally, AMers strayed onto this frequency. Because of the hassle, many people held their conversations about 60 kHz or more above 23. After 40-channel expansion took place, the top 60 kHz of the present class D frequencies, channels 35 through 40, became unofficial sideband-only frequencies, mainly because they were beforehand. Because these frequencies were legalized, some sideband operators, including those running ham gear, quit operating out of band because they felt they now had a place and did not want to lose the new frequencies to AMers.

As a rough estimate, about ⅓ to ½ of the total CB population has probably at one time operated on illegal frequencies. Most of these operators do so when DX is in. When conditions are quiet, there is little non-Class D activity. In fact, there is more illegal AM activity when conditions are quiet. The sidebanders seem to stay put.

Special Activities

There are a few unusual activities that take place in sideband HFing. Slow scan television is around 27.985, just 15 kHz below 10 meters. I have personally never viewed an SSTV signal when the DX is running.

Round table conversations happen frequently. Three or more stations from different parts of North America link up and talk for an hour or more. Virtually all of these HFers use amateur gear and beam antennas.

Phone patches are popular. If an HFer QSOs with another whose location is near his relatives, he will dial up a phone patch without a second thought.

Perhaps one of the most unusual HF clubs is the Eleven M Club. To join, you must own and operate your own business and run all Collins equipment. The club's standby frequency is 27.765, and they only want their members to use this frequency. They generally appear only when DX is running. And the Eleven M is not what you think. The club was supposedly started by eleven millionaires. A rumor circulating about them is that most of these guys are hams who want something a little different to do.

There is also illegal activity below channel 1. For some unexplainable reason, it is all AM activity. When skip starts, this spectrum of frequencies gets filled with traffic. It extends about 300 kHz or more below channel 1. The frequency 26.800 is a popular one because it is exactly 455 kHz below channel 23. A receive crystal for channel 23 put in the transmit crystal socket is a common way to get this frequency.

CB's Popularity

Because CB became so popular in a short period of time, the FCC had to legalize idle chitchat. I really do not think it affected CB's growth. Psychiatrists have come up with many reasons why CB has become so popular so quickly, but I do not agree with any of these.

I think there is a little bit of a ham in everyone. Most CBers do not know how their radio works, but why is that so bad? A lot of people, including some hams, do not understand how a Polaroid camera works or understand every part of a car, but this does not prevent them from using these items and getting good results.

What attracts people to CB is the fact that they can push a button on a microphone and talk to someone

else across town or further away. All this can be done without interconnecting wires. This is what attracted me to radio and this is what initially attracts every ham to amateur radio.

CB has proven there is strength in numbers. As more license applications came in, the FCC relaxed the rules. They allowed higher antenna placement, permitted idle conversation, changed the rules so that only the sender needed to use his call letters, and expanded the number of channels. Most of these changes happened in a relatively short period of time. No one really worked together as a group to achieve these ends, although I will admit that the EIA lobbies wield quite a bit of force.

Yet 350,000 hams, who generally know radio well and work in unison for the most part, cannot persuade the FCC to allow phone operations in a large segment of the 20 meter band now allocated to CW.

Many CBers would like even more expansion on 27 MHz, but the FCC will not expand any further because of intermodulated products resulting from 455 kHz i-fs. Now that 220 MHz is not available, CB will probably end up around 800 or 900 MHz if there is any further expansion. Antennas with huge amounts of gain would be possible, and so would moonbounce. It would be an ideal hobby band. Skip would be all but totally eliminated, and so would interference to other devices. Skip on 11 meters is the main reason HFing exists. HF activity just is not there unless skip is present. ■

70-Watt Shoes for the IC-502

—put some punch in that 6m signal

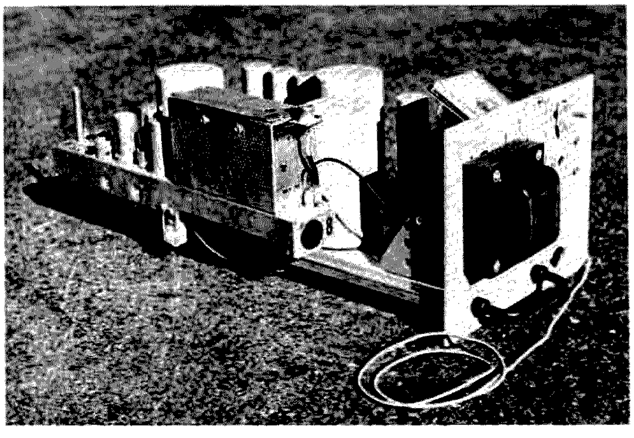
George Hovorka WA1PDY
John Hovorka, Jr.
674 Brush Hill Rd.
Milton MA 02186

The IC-502 is an excellent 6 meter transceiver for the money, but sometimes a little more power is very useful, especially during skip openings. Here is a linear amplifier that you can build at little or no cost, which runs about seventy Watts input. The heart of this amplifier is a surplus tube-type low-band Motorola FM transmitter strip. I bought mine for $1.00 at a local hamfest. Only the final amplifier of the transmitter strip is actually used, so the condition of the strip is unimportant. The advantage of my scheme is that the critical VHF wiring, neutralizing, and shielding, as well as the procurement of rf components is all taken care of for you. Essentially, this project consists of modifying the transmitter strip, building a power supply, and creating the relay switching for the amplifier.

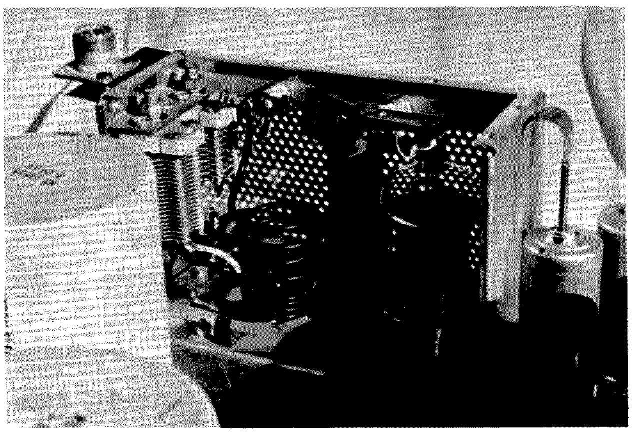
This amplifier will also work well with low-power AM transceivers, such as the Heathkit Sixer and the Lafayette HA-650.

Selecting a Transmitter Strip

This conversion is based on a Motorola TA104 series low-band transmitter strip. These can be easily recognized by their long, thin appearance, and a large multi-turn tank coil. This transmitter series covers the 25-to-54-MHz range in 5-MHz segments. To find the



Completed amplifier. The power transformer is in the foreground, and C1 can be seen attached below the transmitter strip.



Power amplifier coil. Note cut-down tank coil.

frequency range of a particular transmitter, first locate its identification numbers which are stamped in black ink, usually around the final amplifier compartment. These numbers should either be TU113 or TU113-C2. After the identification number, there is a one- or two-letter suffix. This denotes the frequency range of the transmitter. Before you go out shopping for your transmitter strip, make a copy of the suffix frequency code shown in Fig. 1's caption and keep it handy.

The unit covered by this article is an MM-type (35-40 MHz). This type often shows up at low prices because it requires a major conversion job to move it up to 6 meters or down to 10 meters. This poses no problem for its use in this project, since only the final amplifier is employed and only two coils need to be modified.

One final note: If your transmitter strip is other than the HH (50-54) type, be sure to remove the T-section harmonic filter. This filter is located next to the antenna relay which is directly underneath the final amplifier compartment. It consists of two air-wound coils and three capacitors mounted on a tie lug strip. Remove this filter and run a wire directly from the output coupling coil, L2, to the antenna relay.

Construction

A heavy chassis should be used for the base. In my prototype, I used an old dc power supply as a starting point. The main power transformer is not critical. One from an old TV set will work fine. The bias transformer is a six-volt filament transformer connected in backwards. The high-voltage diodes are from Poly Paks and cost $1.00 for five. Be sure to use diode-protection resistor-capacitor networks across each diode. Also, be sure to use bleeder resistors across the filter capacitors. The plate milliamp meter is noncritical, but be sure that it is well insulated above ground.

To convert the transmitter final amplifier, it is necessary to use a grid-dip meter. If you don't own one, check with your local repeater group. You will probably find a ham who will loan you one.

To modify the transmitter strip, first cut the tank coil down four turns. Check for resonance at 50 megahertz by rotating the plate tune control. The resonance dip should occur with the plate tune capacitor half meshed. Next, remove T3, and take off seven turns from the top winding. With T3's top slug halfway in, connect capacitor C1 in parallel with the top winding of T3, and check for resonance at 50 megahertz. I used a variable capacitor for C1 because T3's slug is hard to tune without a special tuning tool. Now replace T3, and complete the wiring. I mounted C1 on a piece of scrap plastic, but any suitable insulation will do.

Since there are no external relay contacts provided with the IC-502, I used a simple hand switch arrangement to key the amplifier. I connected a microswitch to a ten-foot cord which runs to the amplifier. When I am using the amplifier, I hold the push-to-talk mike in one hand, and the microswitch in the other. Alternatively, a foot switch could be used for this function. During standby periods, the bottom of the bias pot is lifted above ground by opening a pair of contacts on relay RLY1. This biases the grid of the 6146 into the cutoff region, which results in cooler operation of the final tube. Relay RLY1 is a twelve-volt DPDT type,

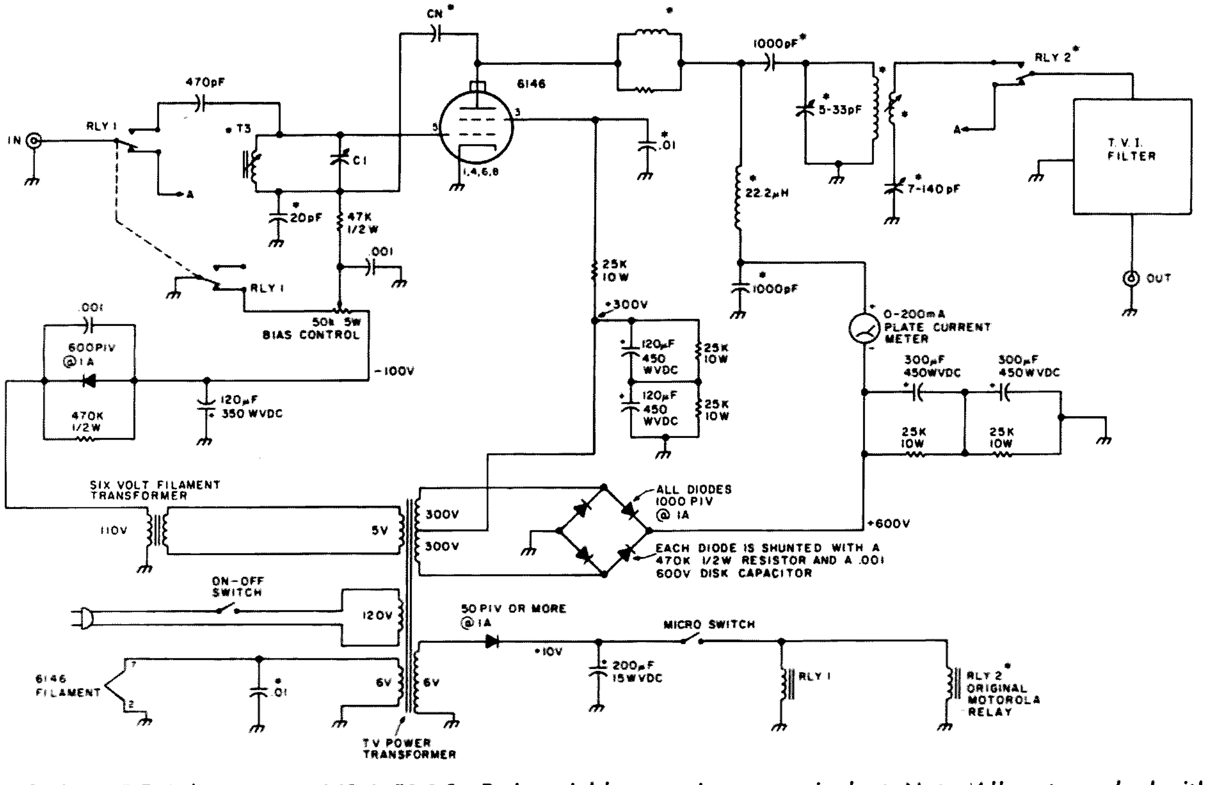


Fig. 1. C1 is an E.F. Johnson-type 148-4, 50-3.2-pF air-variable capacitor or equivalent. Note: All parts marked with an asterisk are from the Motorola transmitter strip which is a TA234 series. The relays are shown in the receive position. L—25-30 MHz; ML—30-35 MHz; MM—35-40 MHz; HL,—40-45 MHz; HM—45-50 MHz; HH—50-54 MHz.

and RLY2 is the original antenna changeover relay in the transmitter strip. All of the rf wiring should be done with RG-58/U coaxial cable. Except for insulating the high-voltage filter capacitors, the rest of the wiring is noncritical.

Some sort of 6 meter TVI filter should be placed on the output side of the amplifier to ensure that it meets FCC harmonic suppression requirements.

Tune-Up

Without any rf drive applied to the amplifier, adjust the grid bias control so that the plate idle current is about twenty milliamps. Next, connect an swr bridge between the amplifier and the exciter. Adjust the exciter to the frequency you most commonly use (such as 50.11 MHz), and place it in the tune position. In the case of the IC-502, place the transceiver in the CW position, and put the key down. Then with the amplifier off, adjust C1 for the lowest swr. With the amplifier peaked for 50.11 MHz, I am able to QSY up to 50.4 MHz without any substantial drop in power.

Over the past few months, the on-the-air reports which I have gotten while using the amplifier have been gratifying. Stations that I have contacted on a regular basis report about a 4 S-unit improvement when the amplifier is turned on. Often, over long tropospheric bending paths of 400 miles or more, the amplifier has made the difference between whether I was able to make a contact or not. If you construct one of these 6 meter amplifiers, I am sure you will find it a valuable asset to your station. ■

NOTE to 73 Subscribers

From time to time 73 Magazine makes its subscriber lists available to carefully-screened companies and organizations whose products, services or information may be of interest to you. In every case, we must approve all organizations wishing to mail to our subscribers. In every case they receive a list of names and addresses only—no other information we may have is divulged. Each organization may use the list only once and agrees never to make any personal or telephone solicitations from it.

The overwhelming majority of our subscribers appreciate this controlled use of our mailing lists—it helps them shop conveniently by mail for products and services they need, often at substantial savings. A few people prefer their names not be used. It is to them we address this message.

If you do *not* wish to be a part of this service, please complete the form below . . . your name will not be used in this manner for any reason.

(If you asked us in the past to remove your name from our lists, there is no need to repeat the request.) Please allow about six weeks for your request to take effect.

☐ I wish to have my name removed from the list of subscribers receiving mail other than the regular subscription to 73 Magazine.

The Big Bopper

As an interested amateur, you probably have heard many on-the-air and off-the-air conversations discussing phased antennas. If you have never operated a phased array, you may have wondered—with honest skepticism—whether they really perform well. In particular, are they generally equivalent to other good arrays and do they have any unique advantages? The answer to both questions is yes. Obviously, there are some qualifications. No single approach to an antenna system can ever be the universal solution to every ham's radiation problem. But if what you need is an effective radiation system on multiple bands with a low physical profile and you want it to be relatively inexpensive as well as easy to construct and maintain, then you may want to consider a vertical array.

The two-tower vertical array described here has directional radiation (and reception) characteristics which are easily rotatable. The system is sturdy, attractive, and readily usable on five bands, with no outdoor adjustments required while operating. Standing-wave ratios are

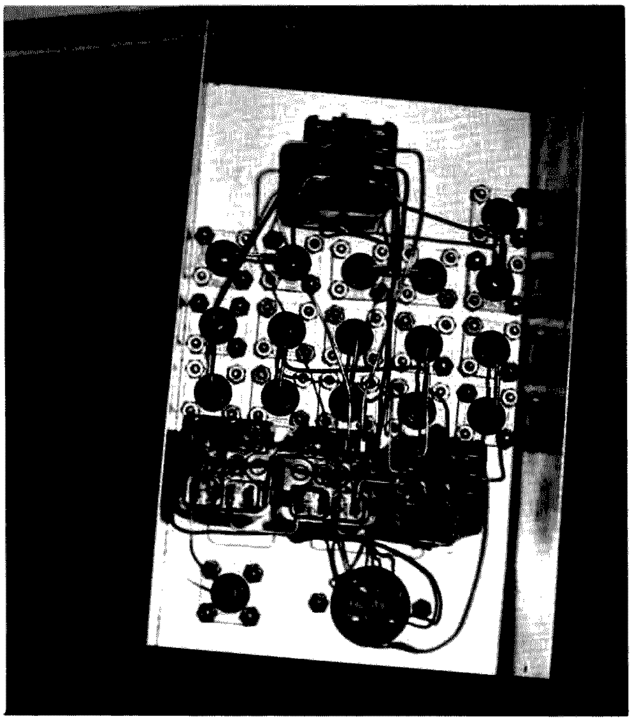

Photo A. Wiring side of the relay switch box.

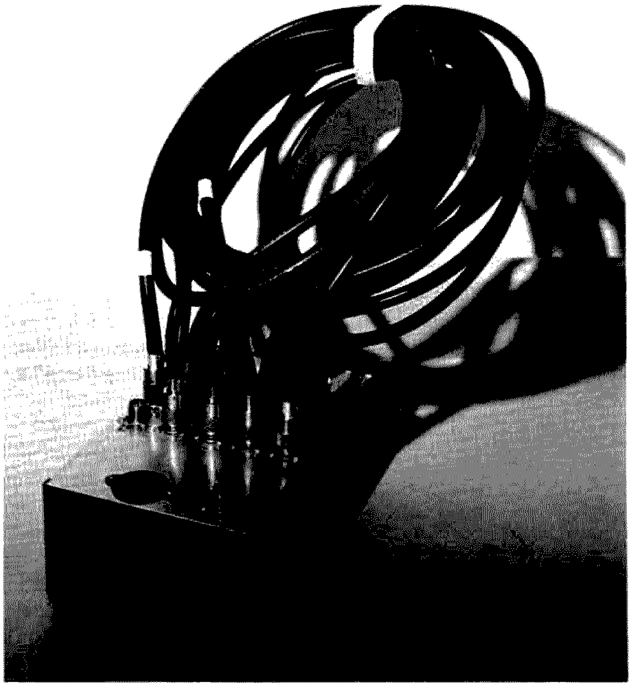

Photo B. Relay switch box "buttoned up" with seven "internal" lines attached.

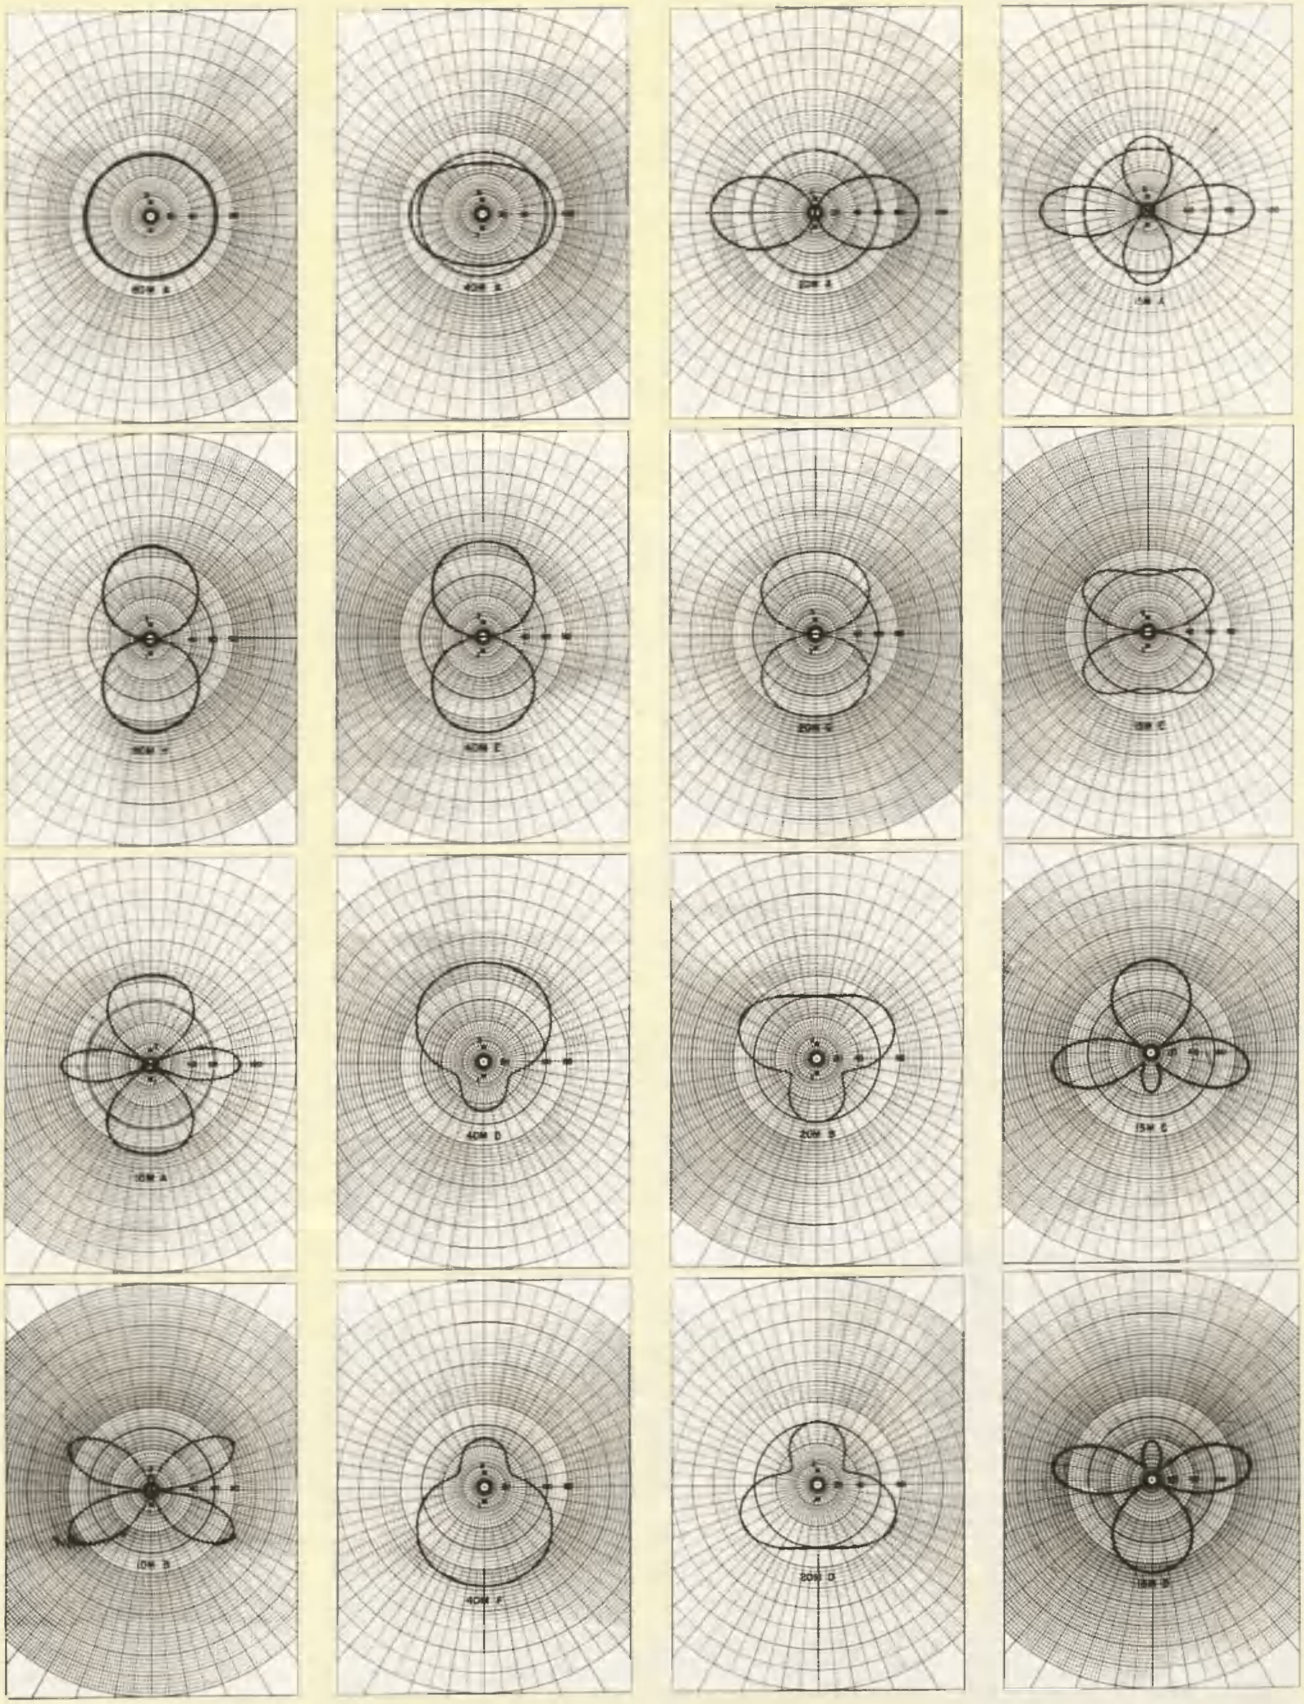

Fig. 1. Idealized radiation patterns. All patterns represent field intensity from 100 radiated Watts. Dots 1 and 2 represent towers 1 and 2. Capital letters represent switch positions. Circles = 61.8 millivolts/meter at one mile. This is the field intensity from a single tower with the same 100 Watts radiated.

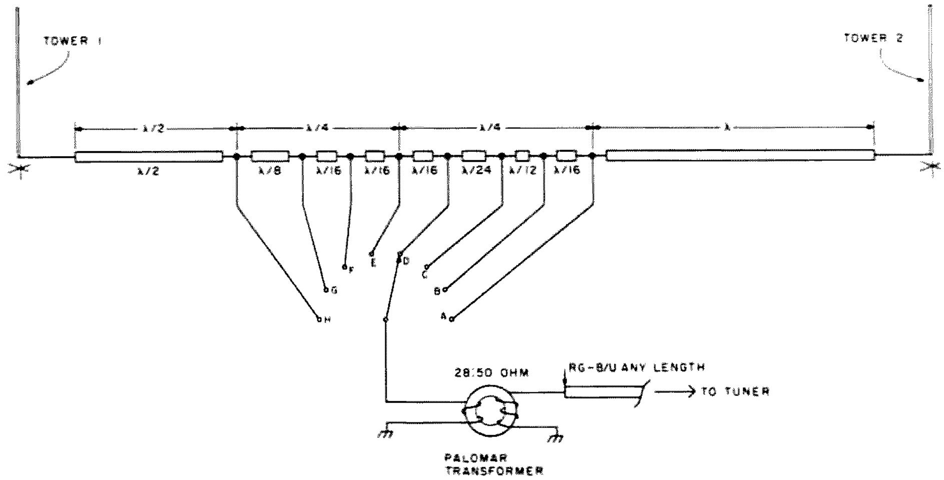

Fig. 2. Block diagram. All notation refers to 40 meters only. All cable and delay lines are RG-8/U or a 50-Ohm equivalent. The transformer is a Palomar Engineers or equivalent (see text). Towers and trapped units on each band are Hustler 4-BTV or equivalent.

moderate under all conditions of operation. The transmission line can be any convenient length. An antenna tuner or matching network is recommended between the transmitter and the antenna system.

The effects of mutual impedance on the array operation have been determined. The radiation patterns have been calculated for typical amateur-level field intensities. Importantly, the patterns recognize the effects of any unbalanced tower currents which sometimes result. The construction of the array, and its operation, is completely straightforward and uncomplicated. It does not require great resources, either real estate or budget. It may be especially attractive if you have been denied a more conventional beam because of zoning restrictions, house construction limitations, or general appearance considerations.

Since the tower separation is fixed, the array cannot be equally directional on all five bands. Offsetting this quality is the ability of the system to operate on five bands with the turn of an indoor switch. It is emphasized that this ability to operate on all major bands with variable directional enhancement on each band is a capability that is not a commonplace feature of typical antenna systems. Also, as will be seen, once the system is tuned to a pattern, it is very tolerant of frequency shifts within a band and can be characterized as having quite a flat load response.

There is no special design requirement for the individual trapped towers. For symmetry, it is recommended that they be nearly the same. Commercial units are readily available and are competitively priced. If your machine shop facilities are limited, buying the verticals may be the quickest and least expensive approach. On the other hand, if you are more venturesome, or able, various means of trapping are described in the amateur handbooks and periodicals which most of us have in our ham libraries. Actually, you may have one vertical antenna already. In this situation, the array discussed may offer you an easy extension in operating capability, with only incremental cost or effort.

This array effectively uses all of the basic lobe patterns that are intrinsic to a two-tower system with a common feedline. Intentionally omitted are some familiar two-tower patterns—perfect cardioids, for instance—that can be generated only with an elaborate feed system so as to maintain balanced tower currents.

The Design Approach

Vertical antennas—towers—used as the basis of the design approach have a number of appealing qualities. They are unobtrusive in residential neighborhoods. Vertical towers with tuned traps allow easy band changing and multiband operation.

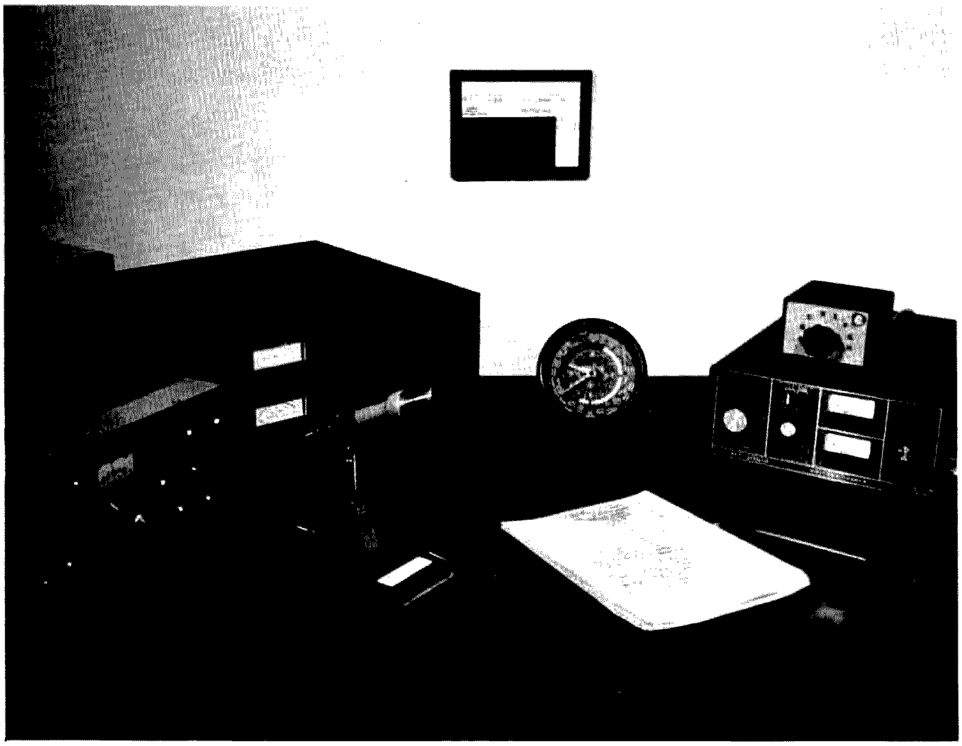

Photo C. The desk control unit in place.

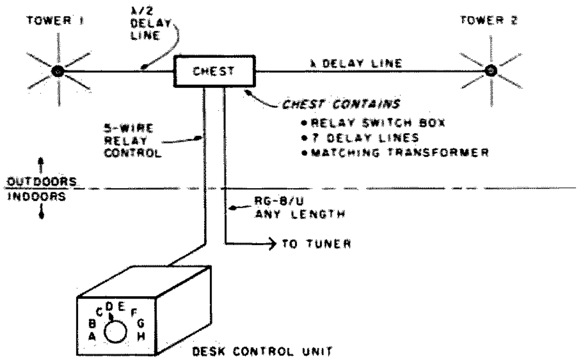

Fig. 3. Bird's-eye view showing the simplicity of the system.

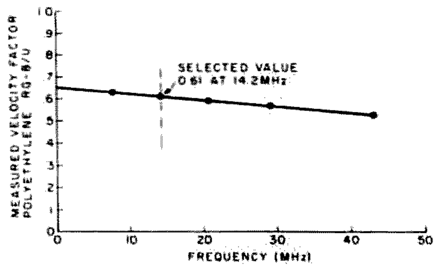

Fig. 4. Velocity factor versus frequency for polyethylene RG-8/U.

The low-angle radiation patterns from verticals enhance DX probabilities for a given transmitter power. The absence of high-angle vertical lobes usually equates to effective use of radiated power. Properly constucted, ground-mounted verticals can have low losses and are structurally sound in almost all weather.

For 40 meter and 80 meter operation, a two-tower vertical system is one of the few practical options that can be used to enhance directivity. This is especially true if rotation of the pattern is desired. Typically, at these frequencies, the beam element lengths in conventional arrays become too ponderous for most hams to cope with.

Finally, in the two-tower system, no mechanism or external rotators are required. The quick switching of the lobe patterns is especially handy for reception when operating in a net or group. Often the compass bearing between received stations is quite wide. Quick optimization of the received signal is a real operating advantage. Sometimes, too, it is helpful to be able to partially null an interfering signal.

How This Antenna System Operates

The two towers are physically separated by λ/4 on 40 meters (34′5″). This is a separation distance that will comfortably fit on many home lots. There is an eight-position switch at the operator's position that selects between the lobe patterns (Fig. 1). For example, switch position D on the 40 meter band selects a paddle-shaped pattern directed off the top end of the axis. Switch position F on the 40 meter band is an identical paddle-shaped pattern, but directed off the bottom end of the axis. The absolute geographic direction is determined by the tower axis orientation.

It is worth noting again that the division of current between the towers affects the pattern generated. Yet the current division between towers, with a common feedline, is a function of the tower self-impedances—including mutual impedance—as transformed through the delay lines to the feed-in point. The individual tower impedances, in turn, for a given current phasing, are a function of the current division between them.[1] Sound circular? For example, it is possible with some patterns and phasings to initiate a multivibrator-type action. As a tower current goes down, the tower impedance goes up, which causes the current to go down further . . . etc. The resulting radiation pattern degenerates toward a single tower pattern or a circle. It can be speculated that such action has discouraged unsuspecting experimenters in the past when actual performance compared poorly with anticipated pattern enhancement.

These degenerative conditions have been avoided in this array. But to avoid them, some two-tower patterns, as shown in a *Radio Engineering Handbook* or similar source, are not available in practice. Uncritical referencing to tables of these patterns is a common error. Such handbook displays are normally predicated on towers which are λ/4 high and which have equal currents in each tower. Maintaining equal currents under all conditions of operation and switching is not an easy trick. Instead, the lobe patterns in Fig. 1 are based on the unequal currents which occur normally. The patterns give good emphasis and direction selection on each band. By orientating the tower axis with care, good world coverage can be obtained.

All patterns as shown in Fig. 1 are "idealized," meaning that they are computed, not measured, and are assumed to be generated over perfectly conducting earth. For most ham installation planning jobs, these assumptions are quite acceptable. The

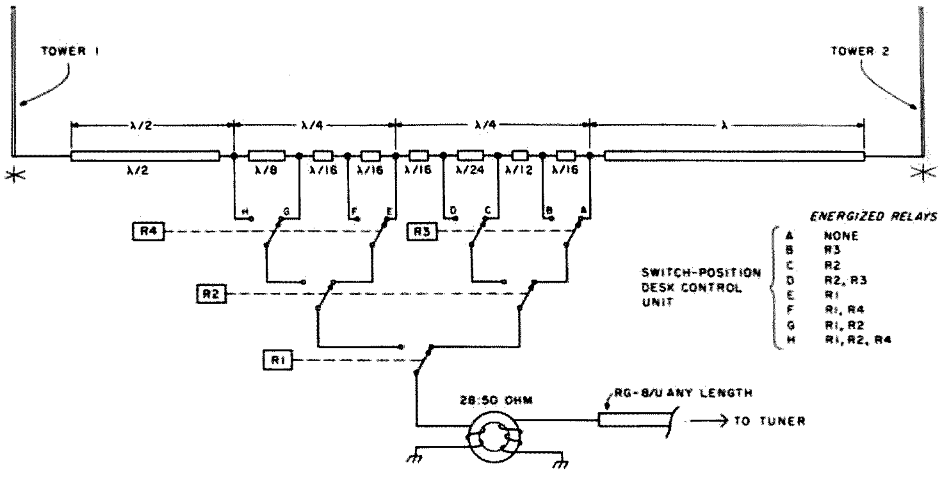

Fig. 5. Relay circuit. All relays are shown at rest. All wavelengths refer to 40 meters only.

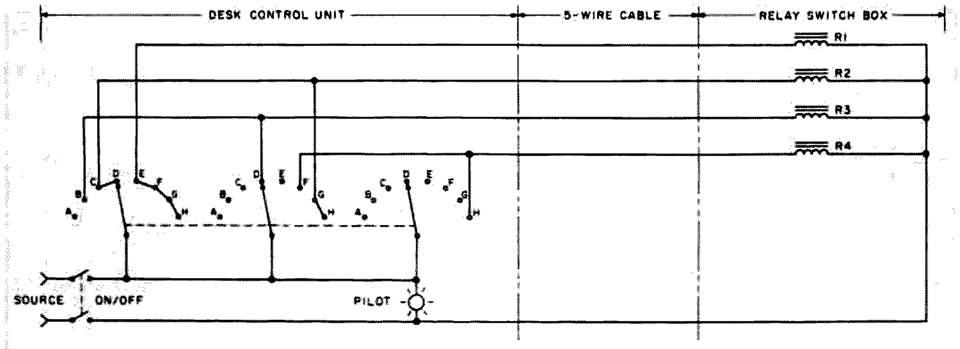

Fig. 6. Relay coil-control circuit.

charts are calibrated in millivolts/meter for a radius of one mile with a total rf radiated power of 100 Watts. To estimate the field strength for a different radiated power, P_2, it is only necessary to multiply the chart reading in the chosen direction by $\sqrt{P_2/P_1}$. In our case, P_1 is 100 Watts. The circles in the charts represent 61.8 millivolts/meter at one mile, which is the field intensity that theoretically would be obtained if the 100 reference Watts were to be radiated from a single vertical tower.

The Block Diagram

The antenna system is shown in block diagram form in Fig. 2. For consistency, all notations in Fig. 2 and throughout this article relating to wavelength or delay degrees will refer to 40 meter operation. Conversion to other bands is then straightforward.

Although the towers are physically λ/4 apart (90°), they are separated electrically by two wavelengths of delay line in nine unequal sections. The electrical centerpoint is at A. The feed-in point of the transmission line is determined by an eight-position switch.

In the D position, as shown, there is a 13/16λ delay to tower 1 and a 19/16λ delay to tower 2. In other words, the current in tower 2 lags the current in tower 1 by the difference in delays, or: 19/16λ − 13/16λ = 6/16λ = 3/8λ = 135°. At the same switch position, consider 20 meter operation. All electrical dimensions are now doubled. The towers are physically separated by 180 electrical degrees. Tower 2 current now lags tower 1 current by twice the amount at 40 meters, or 270°.

The eight-position switch function could be done manually as is illustrated. Such manual switching would be quite awkward in most operating situations, since the switch would necessarily be outdoors. Instead, the equivalent function is done remotely with four relays. The relay circuit and the matching transformer will be discussed in a later section.

The specification of trapped antennas for the towers is important. For predictable radiation pattern generation, it is desirable that each tower be an electrical quarter wavelength high for each operating band (at least no higher than 5/8 λ). Trapping achieves this condition. It may be tempting to try to use untrapped 40 or 80 meter quarter-wavelength towers for all bands. Such untrapped tower heights, when used on high frequency bands such as 10 or 15 meters, can cause confusion and difficulty. In effect, each tower can become a resonant "longwire" with the associated intricate radiation pattern. Lossy high-angle lobes can result. The interaction of these complex patterns in a switchable two-tower array is apt to result in unpredictable and disappointing results without careful analysis.

Electrical wavelength	Physical length (vel. fac. = 0.61)
λ	84'8"*
λ/2	42'4"*
λ/8	10'7"
λ/12	7'.5"
λ/16	5'3.5"
λ/24	3'6.25"

*Table 1. Physical lengths of delay line sections. *Initially cut long and trimmed to final length with a dip meter (see text).*

Construction Features

One real advantage of this array is its easy and straightforward adaptation to construction. For instance, the full λ length of delay line to tower 2 and the λ/2 length of delay line to tower 1 permit the physical grouping of a switch box plus seven of the delay lines conveniently away from both towers. This statement allows for the physical shortening of the delay lines to accommodate transmission line velocity factors. This arrangement flexibility is often useful for appearance or screening considerations (Fig. 3).

While on the subject of velocity factors, it may be helpful to review my own experience. Perhaps I should have known better, but I was unprepared for calibrated dip-meter measurement results, which indicate that the velocity factor in polyethylene RG-8/U varies with frequency (Fig. 4). A review of the technical literature that I have, plus manufacturer's data on hand, discloses no mention of this quality. A single standard "nominal" value for the velocity factor is usually given. Other experimenters may also have this gap in their information. Obviously, knowledge of this variable is significant if the same cable is to be used for generating specific delays, but at different frequencies—as in this array. I selected a velocity factor of 0.61 obtained at 14.2 MHz. This is a compromise value. Errors introduced on other bands are within reasonable limits with this value. Table 1 lists the physical lengths I have used.

It is suggested that the λ length of delay line, and also the λ/2 length of delay line, be cut a little long. Then, with all of the delay lines attached to the switch box but not connected at the towers, balance and trim the lines from midpoint A outward with a dip meter. This balancing will minimize any discontinuity effects in the switched leg due to relay points or coax hardware.

The Relay Switching Circuit

The functional switch in Fig. 2 is replaced by the relay circuit in Fig. 5. The switching relays are conventional medium-power units and need not be the expensive coax type. They should have two sets of SPDT contact points. A compact physical design is suggested. It is important that they have sufficiently heavy-duty contact points

to be able to handle the currents involved. A contact current rating of 10 Amps or better will be adequate in most applications. Obviously, the relays should have good insulation and a low inductance switch path. Contact resistance should not be a problem since full rf current flows through any contacts that are used.

The relay coil-control cable is a five-wire cable. Since the cable runs from the shack to the switch box outside, it is likely to either be buried or at least to touch the earth. As a result, conventional safety precautions require that the relay coils should either be of the low-voltage type or else should be isolated with a suitable transformer arrangement.

In my installation, the relays are housed in an aluminum box, 3½ x 6 x 10 inches (Photos A and B). This box also serves as a mount for the SO-239 panel receptacles which make the connections to the transmission line and delay lines. This arrangement affords good shielding, short connections, and easy assembly and disassembly. Another plus is the ability to make easy substitutions of delay line lengths for experimentation. The layout is not critical and your own design should work well if attention is given to short lead lengths.

Selection of the relays is controlled from a desk control unit which basically consists of a 3-pole, 8-position rotary switch housed in a decorator metal box (Photo C). A pilot light and an on/off switch can be convenient additions. The relay coil-control circuit is detailed in Fig. 6.

Radials and the Ground System

All too frequently, hams underestimate the need for a proper ground system with vertical towers and attempt to skimp by. This is false economy and wastes effort and power. An adequate radial system is a fundamental and necessary component of the total radiation array and should not be neglected. A working rule of thumb is to have a minimum of six radials per band with a minimum length per band of 0.125λ (Photo D).

The Transmission Line, Delay Lines, and Matching Considerations

Although simple in physical appearance, operation, and construction, there are some deceptively involved aspects to the electrical analysis of the array:

- There are two towers with mutual coupling which affects the individual tower impedance.
- Pattern switching affects the load impedance at each tower.
- The towers are not always operated at resonance with the corresponding introduction of reactance of varying magnitude and sign.
- The impedance of the system, viewed from the radial switch, is a resultant of two parallel paths—one to each tower. The length of these paths, their individual impedances, and the current division between them change with switching.

It should be clear that the system—considered as a load—varies under normal operating conditions. For the most part, these operating conditions, while tedious to analyze, are quite solvable with the charts and equations of G. H. Brown, the liberal use of Smith charts, plus the determined application of patience and time with a programmable hand calculator. Fortunately, in practice, the system analysis complexity can largely be ignored while achieving excellent operating results. Anyway, the analysis is mostly needed for determining the pattern shapes when the tower currents are unbalanced. Still, it is realized that most users will want an insight into the operation without the tedium. The following discussion is intended for that purpose.

The range of impedances at the radial switch is such that a broadband transformer can offer very suitable compromise matches to the transmission line. In short, it splits some differences. Two simplified examples will illustrate in principle the general mode of the transformer plus some system features.

Assume that the two towers are physically identical and are operating at resonance in the 20 meter band. Assume further that the resonant resistance of each antenna is a typical 40 Ohms. Assume also for simplicity that there is no mutual impedance! Now let the feed-in point of the transmission line be switch position A, or the midpoint

Band	Tower 1	Tower 2
10	1.30	1.25
15	1.45	1.50
20	1.25	1.15
40	1.20	1.20
80	1.00	1.05

Table 2. Swrs measured at tower base and at tower resonant frequency.

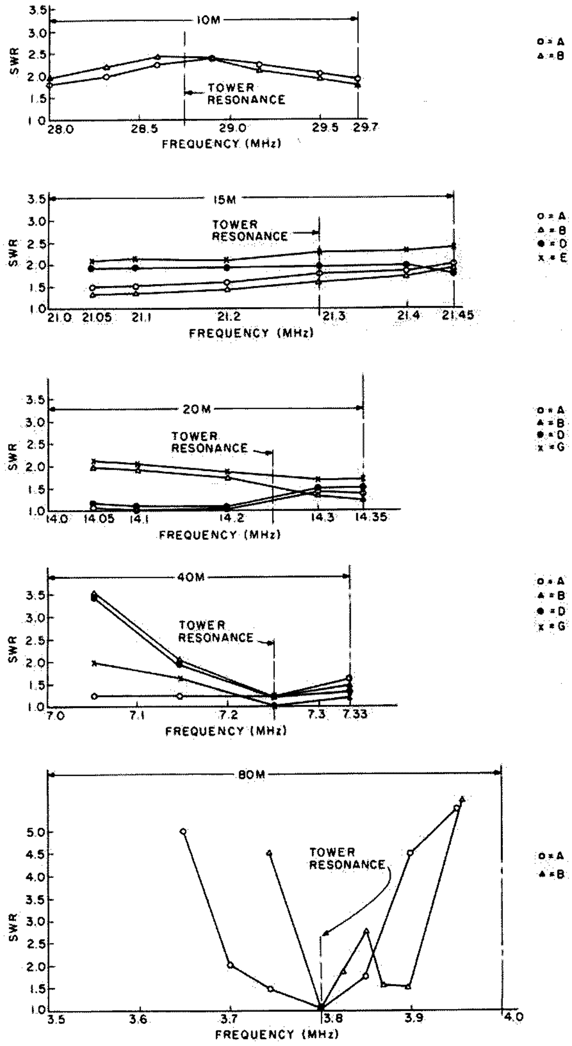

Fig. 7. Swrs versus frequency.

of the delay line. From switch position A, with 20 meter operation, there are two wavelengths of delay line to each tower. Since a half wavelength of transmission line repeats its input at its output, then the resonant resistance of each tower—40 Ohms—will be repeated at A. The two legs are in parallel so that there is a net resistance at A of 20 Ohms. Without a transformer, the 20 Ohms as a load would develop an swr, with the 50-Ohm transmission line of 50/20 = 2.5. However, 20 Ohms through the 1.0:1.8 ratio transformer will appear as 36 Ohms, which will develop an swr of only 1.4—a significant improvement!

For the second example, let the switch tap move to D and keep all other assumptions constant. It may clarify the situation to note that, at 20 meters, there is a half wavelength of line between points E and A. Remembering again that a half wavelength of line repeats its input at its output, the tower 1 resistance is repeated at point H and again at point E. Similarly, tower 2 resistance is repeated at A. The electrical distance from E to D is 1/8λ. The electrical distance from A to D is 3/8λ. The question now becomes what happens at D? Whipping out our handy Smith chart, we find that the resistance of tower 1 will be seen at D as 49 Ohms resistance plus 12.5 Ohms of *inductive* reactance. Likewise, the resistance of tower 2 will be seen at D as 49 Ohms of resistance plus 12.5 Ohms of *capacitive* reactance. Since the reactances are equal and opposite, they will cancel. (This action is true at any tap. Its value will be discussed later.) As in example 1, this leaves us with two resistive legs in parallel. The net parallel resistance is 24.5 Ohms. This resistance, seen through the transformer, will appear as 44.1 Ohms, which, in turn, will generate an swr of only 1.13.

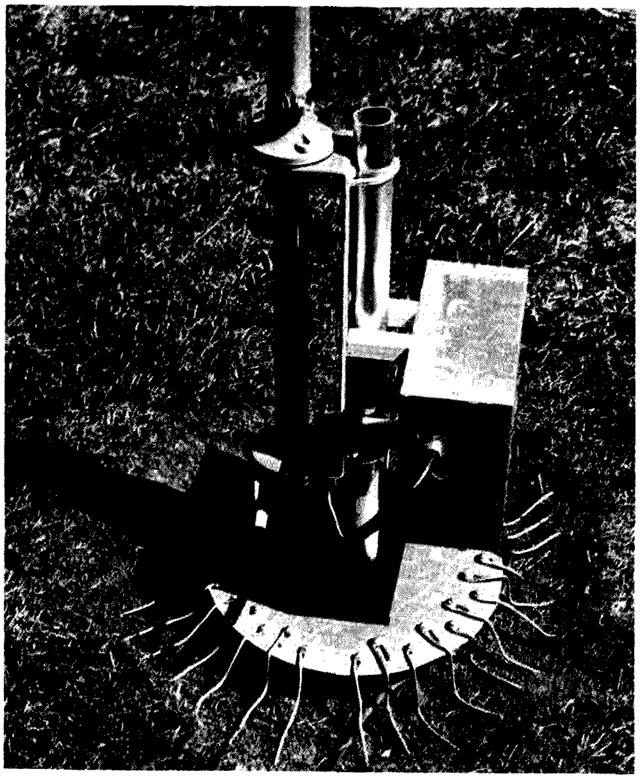

Photo D. The radial system. The aluminum box is handy, but not necessary. It is used to weather protect a PL-239, which was used for cable length experimentation.

Unfortunately, when mutual impedance is reintroduced into our assumptions, the reactive components do not always cancel at all times. Also, the self-resistance of the towers may become different, which would mean that the currents will no longer be the same in each tower. Nevertheless, the function of the transformer can be understood as an impedance leveler and, in fact, practical experimentation is easy.

The transformer itself is a ferrite core unit. I use the Palomar transformer at the nominal ratio of 28:50 Ohms. Roll-your-own transformer winders should have little difficulty achieving the 1.0:1.8 ratio or close to it.[2,3] The turns ratio is not excessively critical, and some experimentation with ratios may be rewarding. It has been my experience that swrs for a favored band can be improved, but usually at some expense to another band.

Adjustments/Tuning

The first operation in adjustment is to tune the towers individually to the same frequency on each band. Other things being equal, a midband resonant frequency will probably give better overall results than a frequency near band edge. Assuming the absence of an rf bridge, probably the most direct alignment technique is to measure the swr at the base of each tower and adjust for minimum. To avoid mutual coupling effects, the other tower should be removed from its standard and placed out of the immediate area.

It will be remembered that an ideal vertical λ/4 tower has a resonant resistance of about 36 Ohms. Thus, with a 50-Ohm transmission line, the swr for an ideal tower would be 50/36 = 1.4. Some hams are confused about this point—probably by advertising claims—and expect an swr of 1.0 or close to it.

The swrs that I measure on the transmission-line side of the matching transformer are shown in Fig. 7. These moderate swrs represent no threat to RG-8/U, even at full legal power. Coax losses at these ratios are insignificant. Most antenna tuners can easily cope with these ratios and will present a perfect load to the transceiver or linear amplifier.

Table 2 lists the swrs I measure at the base of each tower. Superficially, it would appear that I have the best adjustment on 80 meters where the swrs are the lowest. The contrary is the case. My towers are telling me that I have an inadequate radial system on 80 meters. In effect, I have a dissipative ground resistance in series with the radiation resistance, and, therefore, the total resistance is raised. The net resistance at 80 meters nearly matches the transmission line characteristic impedance. Although this raised overall resistance gives a nice low swr, it also indicates that I am wasting some valuable rf power heating the ground!

Perhaps of more interest is the shape of the swr curves in Fig. 7. For the most part, 80 meters excepted, they do not have the familiar lopsided, saucer-shaped, resonant curves. Instead, they tend to be gently curved and be level, or have a slight tilt. That is, *the swr does not change appreciably* with change in operating frequency! This is a feature of the system. Stated another way, once an antenna tuner is adjusted for a par-

ticular lobe pattern, at a particular frequency, it is usually unnecessary to readjust it much while operating across a significant band segment. For emphasis, it should be noted that the chart for the 10 meter band has a 5:1 compression in its frequency scale when compared to the other bands. Its flatness is thus even more impressive.

For an explanation of these unusual swr curve shapes, recall that, in our second example, there was a cancelling of reactance at each switch tap, *providing that there is an integral number of half wavelengths of delay line between towers.* If the operating frequency is moved away from the resonant frequency of the towers, an identical reactive component will be introduced at each tower. These reactive components will tend to cancel at the taps, leaving only resistance. It is like having a built-in compensating tuner!

In addition to matching the antenna system to the output pi network of your transceiver or linear amplifier, an antenna tuner gives added protection against spurious radiation. This antenna system is an excellent radiator on all bands at all times! It will not filter nor inhibit any undesired harmonics. An antenna tuner is an investment in tranquillity. ■

Contests

from page 30

RS(T) and 3-digit serial number starting with 001.

SCORING:

European stations count 1 point per QSO on any band; non-European stations score 1 point per QSO on 20 through 10 meters, and 3 points per 80/40 meter QSO. Count every call area in the above-mentioned countries on every band as a multiplier, e.g., LA1 = LB1 = LJ1 and SM3 = SK3 = SL3. A portable station in Norway or Denmark counts as the 10th call area, e.g., W2XXX/OZ counts for OZ0. Some countries have no geographical call areas, but count this contest as if they had. The sum of all complete QSO points from all bands multiplied by the sum of multipliers from all bands is the final score.

AWARDS:

Certificates awarded to the highest-scoring station in each participating country and US call area in each operating class separately on CW and phone. A special SAC-plaque will be given to the continental winners on both CW and phone. A reasonable score is requested for both certificates and plaques. Depending on the number of contestants in each country, the contest committee will consider more certificates.

ENTRIES:

Write separate logs for CW and phone. The logs are to be filled in in the following order: date and time in GMT, station worked, sent and received message, multiplier, and points. Separate logs for each band are recommended. On the summary sheet the contestant will write his/her callsign, name and address, the final result, the operating class, and a signature that he/she fully agrees to the rules. The logs must be mailed no later than October 15 and sent to: SRAL, SAC Contest Committee, PO Box 306, SF-00101 Helsinki 10, Finland. The decisions of the contest committee are final and definite and they reserve the right to change the rules. Usual disqualification rules.

DELTA QSO PARTY

Starts: 1800 GMT September 29
Ends: 2400 GMT September 30

All amateurs are invited to participate in the 10th annual party which is sponsored by the Delta Division of the ARRL. Amateurs outside of the Delta Division (Arkansas, Louisiana, Mississippi, Tennessee) will attempt to contact as many stations inside of the Delta Division. Delta Division stations will attempt to contact as many stations both inside and outside of the division. Stations may be worked on each band/mode; portables and mobiles may be reworked on the same band/mode if they change counties.

FREQUENCIES:

CW—3550, 7050, 14050, 21050, 28050.

SSB—3990, 7290, 14290, 21390, 28590.

Novice—3725, 7125, 21125, 28125.

EXCHANGE:

QSO number, RST, and QTH (ARRL section for non-Delta Division; county and state for Delta Division).

SCORING:

Delta Division stations score number of QSOs times the number of ARRL sections (75 maximum); outside Delta Division score number of QSOs times the number of counties worked (316 maximum). DX stations may be worked by Delta Division stations but do not count as multipliers.

ENTRIES AND AWARDS:

Logs must include date/time, station worked, exchange, band, emission, and multiplier. Logs must be postmarked no later than October 21 to be eligible for award consideration. Logs will be returned if requested. Send logs to Malcolm P. Keown W5XX, 213 Moonmist, Vicksburg MS 39180. All amateurs contacting 5 different stations in each of the 4 states comprising the Delta Division will receive a certificate. Section awards to the 3 highest-scoring stations in each Delta Division state, 4th and 5th place if warranted; section awards to high-scoring stations in each ARRL section and country outside Delta Division, 2nd and 3rd if warranted. Plaques to high-scoring stations both inside and outside of the division and to high-scoring portable and mobile stations in the division. Another plaque to the high-scoring Delta Division club station (no limit to number of operators or transmitters, but all QSOs must be made from same QTH).

COLLEGE RADIO SCRIMMAGE

Starts: 1900 GMT September 30
Ends: 0100 GMT September 31

Entry classes: 1) alumni and 2) club station. Open to all amateurs; alumni may work other alumni and club stations. Entry may have one or more operators but must have only one transmitter (no distinction between single- and multi-operator).

EXCHANGE:

Name of college, junior college, or university you last attended and the last two digits of the year you graduated, will graduate, or last attended. Club stations substitute the words "Amateur Radio Club" for number. Non-collegians substitute the words "High School" for college name, but are not eligible for awards and may not be counted as a multiplier.

SCORING:

Stations may be worked once per band. Multiply total QSOs by number of different colleges worked (college counts once regardless of band).

FREQUENCIES:

1815, 3895, 7230, 14280, 21355, 28560.

AWARDS AND ENTRIES:

Trophy for top scorer in each entry class. Certificates as well. Logs must be received by November 1 to be eligible. Send an SASE for results to: Penn State Amateur Radio Club, K3CR, 202 Engr. Unit E, University Park PA 16802.

FALL CLASSIC RADIO EXCHANGE

Starts: 2000 GMT Sunday, September 30
Ends: 0300 GMT Monday, October 1

This contest is sponsored by the Southeast Amateur Radio Club, K8EMY, of Cleveland, Ohio, and is open to all. The object is to restore, operate, and enjoy older equipment with like-minded hams. A classic radio is any equipment built since 1945 but at least ten years old (an advantage, but *not required* in the Exchange). The same station may be worked with different equipment combinations and on each mode on each band. General call is "CQ CX" and non-contestants may be worked for credit.

EXCHANGE:

Your name, RST, state/province/country, receiver and transmitter type (home brew send PA tube type, e.g., "6L6").

FREQUENCIES:

CW—up 60 kHz from low band edges.

Phone—3910, 7280, 14280, 21380, 28580.

Novice/Tech—3720, 7120, 21120, 28120.

SCORING:

Multiply total QSOs by number of different receivers, transmitters, states, provinces, and DX countries worked on each band and mode. Multiply that total by your classic multiplier: total years old of all receivers and transmitters used, three QSOs minimum per unit. If equipment is a transceiver, multiply age by two.

ENTRIES AND AWARDS:

Certificates and other appropriate memorabilia are awarded periodically for highest scores, longest DX, best excuse, and other "unusual achievements." Send logs, comments, anecdotes, etc., to Stu Stephens K8SJ, 2386 Queenston Rd., Cleveland Heights OH 44118. Include an **SASE** for a copy of the *Classic Radio Newsletter*.

Ham Help

I would like to correspond with any ham using a Heath HW-18-3 160-meter single sideband transceiver on CW as well as SSB.

William Toben W7JGL
1244 W. Schafer Drive
Tucson AZ 85705

I have been taking *73 Magazine* now for three years. I want my Novice license very much. I am 70 years old and blind—my wife reads the magazine to me. I have *73*'s code tape and know the code very well. However, I can't receive too well, as I don't know Braille and can't read back anything after writing it down.

I believe I could pass my theory test. I need to know just what is required for the blind to pass the test and if there is anything else I could get that might help me. I have radios that I listen to all the time, but I would be happy to talk to someone.

Can anyone give me any help or advice?

Raymond L. White
3341 James Avenue
Fort Worth TX 76110

I am looking for meter rewinding information and/or specifications for a replacement meter for a Johnson Viking Challenger transmitter. Thank you.

George L. Smyth N8AMZ
1316 Eastern Ave.
Morgantown WV 26505

I need any information I can get for a Keithley Milliohmmeter Model 502.

Will buy, copy, or pay to have copied information on batteries, operation, calibration, and schematics.

Dave Hammer K0PCL
610 E. South
King City MO 64463

I would like to form an exchange of solar, alternative energy, and anti-nuclear information with thinking hams.

Los Angeles CA 90042

W2NSD/1 NEVER SAY DIE
editorial by Wayne Green

from page 6

... not just for our own egos, but in order to keep newcomers entering our hobby and thus keeping it alive.

Without the support of a national organization, what can we as individuals or even as clubs do to help the situation? Well, getting publicity is not difficult once you recognize how the system works ... ask your terrorist or other politically active group. No, I'm not suggesting that hams start fire bombing police cars; I'm just pointing out that a realization of how television and newspapers select what they think is news will give us some ideas which can allow us to take advantage of a seriously unbalanced situation.

Take a large parade ... maybe thousands of people and floats. That's not news. But if you add six yelling and screaming agitators in a small group jostling the parade, that's what you'll see on the news that evening ... and not the ten thousand people in the parade. No, we don't want to break up parades either ... we just want to understand what *is* news and what is *not* news.

Our getting publicity should take advantage of amateur radio's possibilities. For instance, suppose we set up a national net to check food prices and report the inequities. Then amateurs could set up cars or vans in front of grocery stores with a big report poster showing the comparison between the prices in that store and other stores around the country ... where large price differences are found.

There are plenty of these price inequities to be found, and the project would make television all over the country. Heck, right here in Peterborough you can find 10% to 20% differences in the prices of identical products just between the Grand Union and A&P stores! As long as stores end prices in a 9, we know that these prices are not honest ones ... at least the chances are 90% against their being honest. We know for darned sure that a price ending in 9 is 90% of the time picked because it seems lower than one which is one cent more. If products were honestly priced, the prices would end in a random selection of numbers ... which should reflect the cost of manufacture and distribution. We also know darned well that if the honest price of a product comes out to be, say, 80¢, it will turn up on the store shelf at 89¢, not at 79¢.

There are fewer and fewer products which are not being priced in 10¢ steps, all ending in a 9. The carpet people go in dollar steps, always managing to end in 99. Bless 'em.

Ham communications could do the job, using two meters for price reports in the immediate area and perhaps 20m for long-range comparisons. And if you don't think something like that wouldn't make every television news broadcast in the country, you have another think coming. Hams working to beat down the artificially high prices on food ... hams working to bring honesty to pricing and show up the price gougers.

The gas shortage may not last very long, but we could take advantage of the tremendous interest in this situation by setting up a ham reporting network on two meters in each area which could let motorists know where gas was to be found, where the gas lines were the shortest, and gas prices ... particularly on weekends. Temporary signboards along the major routes, manned by hams (with coordination by a local ham club), would make the news broadcasts. The gas stations could be checked by telephone for the latest news of their situation or checked out by mobile units. It would be a fun project and would provide a real service. Now that the idea is out, if you don't do it, the CBers will, and you'll have to see them on television and in the newspapers. Your choice.

Those are just a couple of ideas. I'm sure you'll be able to come up with more and possibly better ones. Those came to me while I was taking a shower this morning. Take a shower. Let's get amateur radio known and appreciated.

CQ ... DE LEAVENWORTH

The chap in the middle, between the two police officers, has some serious problems. The photo was taken from a video monitor shortly after the arrest of the unhappy chap in the center for shoplifting.

This fellow had previously been into the store, one of the largest ham stores in the country, and had been suspected of gaining a good deal of weight during his earlier visit. This time they were waiting for him, complete with video monitoring and recording. The police were called and arrived to watch him stuffing his coat with books and parts via the TV monitor.

You see him in the Polaroid above, just after having been read his rights and as he was being carted off to the police station for booking.

The monitoring system has worked well, providing the staff with some rather clear pictures of shoplifters for use during later visits, complete with police in the audience. The tape recorder allows a moment by moment replay of the surveillance at any later time ... which helps in the case of any later claims of innocence.

THE ARRL LINE

Every time I tune from 14,200 on up past 14,275 to where the channels are packed solid with nets and QRM, I tend to think of the dividing line at 14,275 kHz as being the ARRL line. This dividing line is there because the League forced the FCC to take away General frequencies. Before the advent of "incentive licensing," there was no such line and General Class licensees had the use of the entire band. Now they're jammed up into half the phone band, away from 99% of the attractive DX ... certainly away from the relatively open frequencies in the lower part of the band ... and from SSTV experimenting.

This all started in 1963 when the League, being run at the time by some old-timers who wanted the ham bands to be back the way they were before the War, pushed through a disastrous piece of legislation. Amateur reaction to the proposals was so furious that it almost stopped the League, despite their inside help via Herb Hoover, Jr. The amateur reaction brought the sale of amateur equipment almost to a halt and stopped the growth of the hobby for over ten years. Talk about disaster!

This was the time when most of the famous names in ham manufacturing disappeared ... Hallicrafters, National, Hammarlund, Johnson, Harvey Wells, B&W, etc. Tuning past 14,275 brings back these memories of the havoc wrought by the League in the 1960s. *73* was too small then to be more than a cry in the wind, but I think that without the cry the League proposal to remove Generals entirely from the major DX bands would have gone through. The retaining of half of the bands by Generals was better than nothing.

The result of all this? Proof that forcing amateurs to upgrade would not work. Many of us held that the FCC should offer rewards such as better call letters rather than taking away frequencies and then giving them back if you upgraded. If you are locked above 14,275, it's something to think about.

SAROC ZOMBIE

That's what they call the dead brought back to life ... or at least some semblance of life ... and it seems apropos for the SAROC hamfest. This is a strictly commercial venture run for profit by a chap in Nevada and it died a couple years ago of extreme neglect. I see a report that this exploitation of amateur

radio has been announced again for next year in Las Vegas.

The main purpose of SAROC is to provide a legal excuse for a few of the ham manufacturers to go to Las Vegas for a vacation in January. The actual business done is a farce. For instance, one major supplier brought in a truckload of ham gear for his exhibit at the last show and over the three days of the show sold $1,500 worth of gear. That's less than one tenth of the minimum acceptable business for him just to break even.

Now, if the show was that lousy when there was still plenty of gas for the California hams to drive over the desert to come, who will be there when gas is in short supply and a lot more expensive? Ten years ago, when FM and repeaters were firing everyone's imagination, the local Vegas FM club ran a hospitality suite. Art Householder of Spectronics also had a hospitality suite where he made everyone crazy with desire for recycled Motorola HT-220s which he pulled from his pockets and sold in a kind of under-the-table atmosphere. It was heady stuff and FMers were king of the roost.

No more. The last show, two years ago, was held together mainly by itinerant hams in town for the concurrent winter Consumer Electronics Show and who came over to the hamfest for a few minutes to see what their poor relatives were doing. Next year, CES will be January 5-8th. The hamfest will be the 10-12th and the Fifth Annual Ham Industry meeting will be in Aspen, Colorado, on January 12-19th. I'll probably hop out on the 7th for a couple of quick days at CES, visit the Wilson factory on the 9th in Vegas, see who was wealthy enough in the industry to "exhibit" at the hamfest, and then poop on up to Aspen for the yearly industry conference and workshops.

SAROC, being run strictly for a profit, has a tremendous charge for attending . . . I think I paid $17 last time . . . and for that I got to wander around a handful of booths. It took me maybe half an hour to see everything. There was no recognizable program. ARMA held a meeting, but many of the manufacturers were unable to find the meeting room, which was very well hidden.

Now, why is Wayne Green so down on SAROC? Is it that I'm getting even because I haven't been asked to speak? No . . . as a matter of fact, I've been asked to speak and have refused. It's a long story and there is a lot of background. It comes down to a question of supporting what I feel are unsavory elements. I sure wish someone would take the time to write an exposé of the people behind this hamfest.

Anyway, between the gas problem and the CES show ending two days before the hamfest, it seems unlikely that the next SAROC will be any improvement over the last one . . . which had CES to help and no gas problems . . . and still was a disaster. Perhaps this commercial show should be put to rest and remembered for its heyday ten years ago instead of its more recent disappointments.

DXERS AND LISTS

A lot of true-blue DXers are very uptight over list operations. For those of you who have not enjoyed the spice of working serious DX, a list of calls is taken by some intermediary and passed along to the rare DX station, who then works the list and only the list. This can be very upsetting for some operator who comes along after the list has been drawn and finds that while he can hear the DX station easily, he can't work him. Oh, bitter anguish!

The operators of rare DX stations have several choices open to them when they get on the air. First, they know that a normal contact is out of the question because every time they stand by there will be dozens, then hundreds, of stations all calling them simultaneously. The din soon gets so great that it is impossible to hear any call distinctly and the tendency then is to wait out the caterwauling until there is just one station left to come back to him.

The encouraging of "tail-ending" quickly screws up everything. The waiting hordes quickly detect what is happening and there soon develops a two or three operator contest to see who can be the last one to call. None of them can even hear the DX station and none will quit the bedlam, so the calling can go on for several minutes. One W5 I know got steamed up at a certain K6 and the two of them refused to budge or listen on the frequency for well over an hour. The poor DX station had gone to bed long before they stopped jamming each other.

Some DX ops like the system where a DX station operates from just outside the US band and tunes for calls. I like this, too, for it doesn't take long to find out where the chap is tuning and jump in the pileup on that frequency.

Having been on the other end of the pileups, I have some observations from the viewpoint of the rare DX station. Newcomers, I've DXed from the following rare and relatively rare spots: JY, OD, 5Z, YK, YA, VU, 9N, FK, VR2, 5W, KS6, FO8, KW6, KG6, KC4, HH, PJ, 4U, OH0, VP9, VP7, and probably some more that don't come right to mind. The main problem in working a lot of stations from a rare location is not in hearing them—it's in pulling the calls apart and getting the individual calls.

After trying every known system for working 'em as fast as possible, which included working by call districts on my own frequency, working from outside the US band and listening on one frequency in it, tuning a small band of frequencies, and working from lists, there was no question . . . the list could beat everything by far.

Well, let me amend that. The list situation works great if you manage to get hold of some sharp operators to gather the lists for you. I somehow always managed to get one or maybe two good ops and one thoroughgoing idiot. I really hate it when I think I have everything set up for some really fast operating. I've rounded up three chaps with good signals to move off my frequency and copy down call letters for me . . . maybe ten at a time. Then all they have to do is come on my channel and read off the list quickly so I can write the calls down and give each one in turn a report. I can run through ten in one minute if I have the calls. And getting the calls shouldn't take more than one minute at best, right?

So on comes my helper with his list: "Hello, Juliet Yankee Eight Alpha Alpha. Juliet Yankee Eight Alpha Alpha, this is Kilo Baker Zero Xray Quebec Quebec. This is Kilo Baker Zero Xray Quebec Quebec in Washington, Nebraska. That's doubleyou whiskey, aye America, ess Sweden, aich hotel, eye Indiana, enn Nancy, gee George, tee Toronto, oh Oregon, enn Nancy. The name here is Wilbur . . . that's doubleyou whiskey, eye Indiana, ell love, bee bravo, you Uruguay, are radio. You're certainly putting a good signal in here, Wayne, really poking the old S-meter around. I have your list for you. I sure hope everyone on the list is going to come up here and find us. Let me know if you're getting me all okay and I'll pass along the list. Juliet Yankee Eight Alpha Alpha, this is Kilo Bravo Zero Xray Queen Queen standing by."

I grunt out a terse "go ahead, quickly, please," stifling an oath. Good old Wilbur comes back, spelling out both of our calls again, apparently in the belief that I may have forgotten not only his call, but my own, too. Then he starts slowly spelling out each call, one at a time, spelling each one twice for me and standing by after each call has been sent, triumphantly. Wilbur is able to take a one-minute task and escalate it to nerve-shattering lengths for all concerned, stretching it out for maybe ten minutes or more. By this time, the other two chaps who have been scrounging calls for me are on channel wanting to give me their lists and I suddenly have thirty stations to work instead of just ten.

Ten works well. Thirty doesn't. Before I can work my way down through even twenty of the chaps, I have some breakers wanting to know who is on there, how can they get into the contact, where is the list being made . . . plus an Italian calling CQ DX with a 40 over 9 signal. When I ask him to stand by, he gives me my report, spells out his name twice, then the name of his town twice (why do most Italian towns have over twenty letters?), and refuses to get off the frequency until I give him my location and agree to QSL.

It is unfortunate that many lists are run in a much slower style. Hopefully, some of the DX operators will read this or hear about it and get moving faster. I heard YK1AA on the other evening and some OK station was running a list for him. It took maybe five minutes for each damned contact . . . and all Rasheed did was swap signal reports and call letters. But it went on with excruciating slowness and drove me and a few hundred others up the wall. I didn't particularly need a contact with Syria; I just wanted an opportunity to say hello to Rasheed since I had visited him and operated from his station a few years back.

Try the live list system with perhaps three good operators, all with good signals and in separate parts of the country, taking calls for the DX station. If you can't clearly read off ten calls, spelling them out as you go for the DX op to copy, in less than one minute, then you need some practice. Once the DX op has the calls, 95% of the work is over . . . he can then stand by for one, get the report, give a report, and get an okay . . . stand by for the next, etc. He doesn't have to spell any calls out or even give his own call more than once every few minutes.

The purpose of most DXpeditions is to work as many stations as possible in a given time . . . so why horse around with slow and frustrating systems?

unique digit enable code, and then output these eight bits of information to the interface. For instance, the value 01010011 will cause a five to be displayed on the fourth digit from the right on the display. The digit enable code in this example is 0011, and the digit enable code for the right-hand display is 0000.

To display the number 3,163,908,332, register pair H is first loaded with the memory address where the two least-significant digits (LSDs, 32) are stored. In Fig. 4, this address is 004 120. Only five memory locations are required to store the 10-digit number, because the number is stored in a packed BCD format. The D register, which is used to store the digit enable code, is then set to zero. The content of register D, which will eventually be latched by the interface hardware, is used to turn on one and only one digit at a time. At DISPL1, the DIGIT subroutine is called, so that the content of memory addressed by register pair H is moved to the A register. Since the data values are stored in memory as packed BCD digits, this subroutine unpacks them. The digit in the four LSBs of the A register is rotated to the left four times, bit by bit. The first digit to be displayed is now in bits D7 through D4 of the A register when the OUTIT subroutine is called.

At OUTIT, the four LSBs of the A register are set to zero by the ANI instruction (the digit to be displayed is in bits D7 through D4). The digit enable code contained in the D register is then added to the BCD number in the A register and the result is output to the interface (OUT 125). When this word is output, the four LSBs determine which digit is enabled and the four MSBs represent the value to be displayed. The first time the OUTIT subroutine is executed, the A register will contain 00100000, because a two must be displayed on the right-hand digit.

At the end of the OUTIT subroutine, the content of the D register (the digit enable code) is incremented from zero to one, preparing it for the next digit enable code. To "intensify" the digit that has just been turned on, the computer executes a time delay at INTENS. Thus the digit is kept on for a period that allows it to be clearly seen. When the 8080 finishes the OUTIT subroutine, it returns to the MOVAM instruction just before the OUTIT subroutine. The A register is loaded with the content of the same memory location addressed by register pair H, only this time the BCD digit contained in bits D7 through D4 must be displayed. This is the second digit from the right in the number 3,163,908,332. The ANI instruction at OUTIT sets bits D4 through D0 to zero and the digit enable code (one) is added to

Fig. 5. Using a look-up table with the multiplexed LED display.

the number and the result output. After incrementing the digit enable code to two, the 8080 again executes the INTENS delay loop, so that the three on the second digit from the right is displayed for a reasonable amount of time. When the RET instruction is executed, the 8080 returns to the INXH instruction just before DISPL1.

The 8080 increments the memory address in register pair H and then examines the digit enable code contained in the D register. If this code is less than 012 (decimal 10), the 8080 jumps back to DISPL1 so that the two BCD digits now addressed by register pair H are displayed. If the digit enable code is equal to 012, then all ten digits in the number have been displayed. If this is the case, the 8080 jumps back to DISPLA so that the memory address in register pair H and the digit enable code in the D register are re-initialized.

As you can see from this program, the 8080 is constantly updating (writing new information out to the interface) the display. New digit enable codes and data values are output to the display every millisecond.

Unfortunately, this "ties up" the microcomputer and it cannot perform any other tasks. Of course, the program listed in Fig. 4 could be converted to a subroutine. If it is called every 15 or 20 ms, the 10-digit number will still be displayed at a reasonably fast rate. However, it may be difficult to program the microcomputer so that the DISPLA subroutine is called this often.

One solution to this problem is to use an interrupt. This means that whenever the 8080 is interrupted, it outputs a numeric value to the next consecutive digit in the display. The microcomputer will have to be interrupted at least 400 times every second for the display not to "flicker." This means that our 10-digit number will be displayed 40 times every second. To interrupt the 8080 so that it "services" the display this frequently, a low frequency oscillator (400 Hz) can be wired to one of the interrupt interfaces previously discussed.[2,3]

The program that services the interrupt and outputs a new eight-bit value to the display interface is very similar to the software in Fig. 3. Because of its length, we have not included a listing of it. The only difference between the two programs is that the 8080 has to store the digit enable code and the address of the memory location that contains the next digit to be displayed. These values must be stored in memory, because register pair H and the D register may be used by the program that was interrupted. Therefore, each time the oscillator interrupts the microcomputer, it has to read from memory the address for the next digit to be displayed and its corresponding digit enable code. After the number is displayed, the digit enable code and the memory address have to be incremented and stored back in memory. To keep this software as simple as possible, it is easiest to store the 10-digit number in ten memory locations, one digit per memory location, rather than "packing" the BCD data.

One feature of our interface that we have not mentioned is the fact that we are limited by the DS8857 to display only the numbers 0 through 9. This device cannot be used if we wish to display the letters A through F, as is often the case if hexadecimal numbers or message codes need to be displayed. To display the hexadecimal characters 0-9 and A-F, the DS8857 must be replaced by a device that can be used to drive individual segments in any combination we desire. The UDN-2981A (Sprague Electric Company, Worcester MA) contains eight individual drivers that can be used in the display interface. This device has eight inputs and eight outputs—each input is interfaced to an individual data bus line by means of a latch circuit and each output is wired through a current-limiting resistor to one of the segment inputs of the display (A-G). If desired, the last driver in the integrated circuit can be used to drive the decimal point in the display. Since the UDN-2981A has eight inputs, an eight-bit output port (latch) will have to be used to interface it to the microcomputer. This means that one output port will be used to output the sequence of ones and zeroes that specifies a specific sequence of segments to be turned on or off. A four-bit output port is also required so that the digit enable code can be output and stored in the interface.

In Fig. 5, there is a look-up table used for converting BCD numbers to seven-segment codes.

The first difference between the programs listed in Figs. 4 and 5 can be seen at DIGIT. After the packed BCD word is moved from memory to the A register, the OUTIT subroutine is called. This means that the first BCD digit to be displayed is in bits D3 through D0 of the A register. At OUTIT, bits D7 through D4 of the A register are set to zero. The content of register pair H is then saved on the stack and register pair H is loaded with the base address of the look-up table. The BCD number in the A register is added to this address. The MVIA and OUT instructions at OKASIS cause the display to be blanked by writing an invalid digit enable code out to the display interface. While the display is blanked, the 8080 moves the bit pattern for the number to be displayed from memory to the A register (MOVAM). Register pair H is then popped off the stack and the seven-segment bit pattern is output to output port 126. The A register is then loaded with the digit enable code which is output to output port 125. When the OUT 125 instruction is executed, the specified digit in the display is turned on. The 8080 executes an intensifying time delay loop before returning to the MOVAM instruction just after DIGIT.

The MOVAM instruction loads the A register with the same packed BCD word that contained the previously displayed digit. However, the BCD digit in bits D7 through D4 must now be displayed. Therefore, bits D7 through D4 are rotated into bits D3 through D0 of the A register before the 8080 executes the instructions at OUTIT which cause the required bit pattern for the seven-segment display to be fetched from the look-up table. The bit pattern followed by a digit enable code is then output to the interface. The remaining instructions in Fig. 5 are the same as the instructions in Fig. 4.

One advantage of using seven or eight individual segment drivers is that you can display any combination of segments that you want. You are no longer limited to the numbers 0-9. If desired, you can display the letters A-F so that hexadecimal numbers can be displayed. For some special applications, some additional letters and words can be displayed, such as H, r, L, o, OIL, HELP, Error, etc.

There is one additional display method that we have not discussed—the use of an external display controller integrated circuit to control the multiplexed display. The Intel Corporation makes a number of these integrated circuits that are compatible with the 4004/4040, 8080, and 8085. These are the 4269, 8279, and 8279-5 integrated circuits. National Semiconductor Corporation also has two display controller integrated circuits that can be used with six-digit displays. One of the devices (MM74C912) can be used to display 0-9 and the other (MM74C917) can be used to display hexadecimal numbers. For additional hardware and software information about multiplexed LED displays, we refer you to reference 4.

Ham Help

I need an operator's manual and schematic for a BC-1031 panoramic adapter. I will gladly pay for all copying and postage.

Chuck Holstein WD5CUG
4721 Lucy Dr.
El Paso TX 79924

I would like to copy or purchase the manual and/or schematic for the Multi-Elmac AF-67 transmitter and power supply. Can anyone help? Thanks.

Al Christman WD8CBJ
Box 44
Granville WV 26534

I have some older VHF equipment that utilizes electron tubes (remember those things?). Anyway, there doesn't appear to be a ready market for the tubes I need and I can't find a distributor who sells them.

If anyone has one or more tubes I list below, I would appreciate hearing from them, particularly those having the 6850. The tubes I need are: 5696, 5718, 5896, 5899, 5902, 5940, 6021, 6112, and 6850. Many thanks.

clerk.

Although the story seems to be changing daily, it now appears that the DXCC desk will not accept TH8JM cards for credit. If you need this one, you will probably have to work John again when he gets his true-blue TL8 license.

TR8AC and TR8GDC recently moved to Alexandria, Egypt, and should be heard signing SU any day.

Anyone needing confirmation for an ET3FMA/9E3FMA/9F3FMA contact from 1965 to 1968 can send an SASE to Don Murray W4WJ, 19700 NW 5 Ct., Miami FL 33169.

ON4UN recently worked CR9AJ on 75 meters to complete his 5BWAZ. Five more QSLs and it will be confirmed. 5BWAZ is easily the most difficult operating award to obtain in all of hamdom.

The correct route for ZS2MI QSLs is WA2IEN, 255 Route 17, Upper Saddle River NJ 07458.

C5ABK has reportedly received permission to operate in CR3 Guinea-Bissau for two weeks in December. He is presently assembling the necessary equipment to make the operation a success and plans to open up on December 1st. QSL to G3LQP.

If you worked HV3SJ on November 11/12 and had your QSL bounced by W6KNH, try again. Logs for that period disappeared for awhile, but now they are safely in the hands of W6KNH, all 45 pages.

As we mentioned last month, several of the deserving were surprised last June when they received a citation from the FCC for contacting HS stations in Thailand. The citation stated that Thailand was on the banned countries list. Those responding received a follow-up form letter from the FCC saying only that in view of the reply, the matter was being closed. Apparently, no form letter exists for apologizing and admitting an error.

The Panamanian government has confirmed to the ARRL that HP9 callsigns have never been issued for use on amateur bands. Communication of any type with stations signing HP9 is illegal.

VR6TC has recently acquired some SSTV gear and has been showing regularly on 14233 kHz from 0530Z. QSL to W6HS.

All KZ5 Canal Zone licenses expire September 30, 1979.

9M2FK reports needing Arkansas, Utah, North Dakota, and South Dakota for WAS and Zone 2 for WAZ. Look for him on 14020 kHz between 1000Z and 1300Z.

Those of you involved in the DX net and/or DX list business should keep in mind that it is possible to violate third-party traffic regulations when passing a list to a DX station. If you compile a list and pass it directly to a station in a non-third-party country, then you could be in violation. If you say "DX1DX call W5USA," then you are in violation. The correct way would be to say "W5USA call DX1DX." If you think this is just nit-picking, then be advised that some FCC monitoring types are on the prowl for just such violations.

Jim Smith P29JS finally received an answer from the Indian government concerning his application for permission to operate from Andaman. Unfortunately, the letter stated that new rules beginning in January, 1979, made it impossible to grant licenses for short stays.

Rumors floated hot and heavy that XZ2P was SP5AUC and that his was a true-blue operation. Unfortunately, the real SP5AUC denied the rumor and that sort of ended that.

While in Poland, we might mention that Polish amateurs are now allowed to work 160 meters between 1750 kHz and 1950 kHz. Maximum power is 10 Watts.

New officers of Murphy's Marauders include Al Meleg N1JW—President, Ron Grzelak K1BW—Vice President, Dan Street K1TO—Activities Manager, and Ron Nevers K1TVM—Secretary/Treasurer. Newsletter editor is Ed Kalin K1RT.

WA1SQB ran off better than 5000 contacts during his HC8 operation in March. He should be setting up in Montserrat this month where he will be signing either VP2MAY or VP2MI.

Last month we mentioned that sending currency through the mails to foreign hams could bring trouble to the recipient. If you are in doubt as to which countries can receive USA currency in the mails, ask your local post office to check through the Foreign Postal Manual for the country in question. Any illegal items are listed in this manual.

If you've worked everything else, then you might try for all the cities and districts in Japan. A full list can be obtained by sending 14 IRCs or $8.00 to Michio Koshimizu JR1BFT, 37-3, Nakano, 1-chome, Nakano-ku, Tokyo 164, Japan.

Tom Wong VE7BC recently returned from a business trip to China. While he was there, he inquired into the possibility of obtaining an operating permit for a future visit. Tom says that the current policy of the Central Government is that there will be no amateur radio operation. It seems that there will probably have to be some top-level changes made before any legitimate operation occurs. Tom feels, however, that this is entirely possible, and with the great interest in amateur radio, something might develop before the end of the year. The feeling still runs strong that when a legitimate operation does surface, it will be by the Chinese themselves and not a group of war-mongering, imperialist, running-dog lackeys, or whomever. Keep the faith.

That Soviet ski team that was signing U0CR successfully reached the North Pole last July.

ZS5DC is Diane Cardell, formerly VQ9DC, now living in Durban. Diane was in on the big Desroches effort by VQ9D, VQ9BP, and others back in 1974.

That HB9APN/BY operation a few months back did not have official approval and is not being accepted for DXCC credit.

Several "goodies" have been checking into the WA2JUQ Net on 14240 kHz. Heard recently were TA1MB, YI1BGD, FH8YL, and ZS2MI on Marion Island. The time to listen is around 0630Z.

Another net to watch is the DX-DX Net on 21280 kHz. Listen from 1600Z.

Vendaland is the third of the nine African homelands being established by South Africa, the first two being S8 Transkei and H5 Bophuthatswana. Independence day is set for September 13 and several ZS types plan to be there for the unveiling. ZS6AK and ZS6ABO will head a contingent of eight Durban DXers planning to make the 200-mile trip. DXCC status is expected to be the same as Transkei and Bophuthatswana, that is, no decision until after WARC 79 and then a favorable decision made retroactive back to the date of independence.

JF1IST/7J showed on schedule from Okino Torishima with a very good signal to most of the states. The one-man effort opened up on June 11th and ran through June 15th with WB8LDH the last station logged at 0653Z. Weather conditions cut short the expected ten-day stay, but some 5500 contacts were made on 6 through 40 meters. QSL to JA1RNH, Itaru Tomita, 1-2-9, Zaimokuza, Kamakura, 248 Japan.

This is the month (September) the ARRL begins accepting Desecheo QSLs for DXCC credit.

Reports have all 7Q7 stations being shut down and their equipment confiscated.

Slim showed from 3Y6CD in June and from 9A1VU earlier in the year.

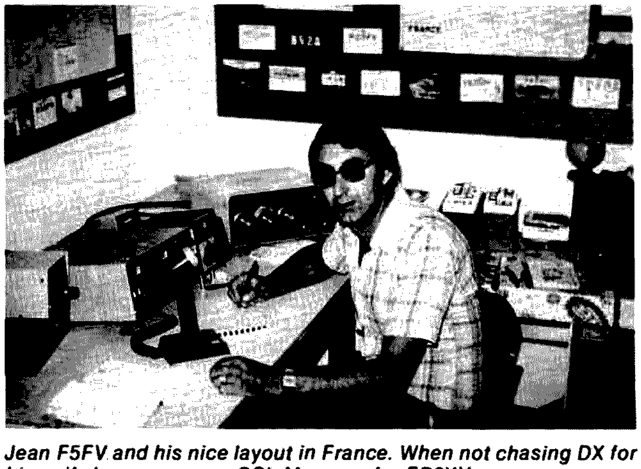
The correct route for all FH8OM/YL QSLs is to Box 86, Dzazoudi, 97600 Mayotte . . . via France.

The Guatemalan Radio Society indicates that TG7AA was Slim and the ARRL is returning the cards without allowing DXCC credit.

There is a multi-national effort being planned for a fifteen-day operation from 3V8 Tunisia this month. Amateurs from France, Italy, and the UK will man as many as ten different stations.

UHF marine-band applicants are being asked to make up their own callsigns until the overworked FCC can get their applications processed and the regular type licenses in the mail.

If you paid more than $20.00 to the FCC between August 1, 1970, and December 31, 1976, you are eligible for a refund. If you are eligible, then you



Jean F5FV and his nice layout in France. When not chasing DX for himself, Jean serves as QSL Manager for FB8XV.

should obtain a copy of the "Phase One Fee Refund Program" instruction and form manual from your nearest FCC field office or Federal Information Center. Check the June *QST* for more information.

Remember that EI8H/anything is always Slim and you will save time and money.

Bill KA2WG writes to remind us all that even though KA stations are not recognized as amateur stations by the Japanese government, they still count as Japan for everything except the All Asia Contest. Any US ham being transferred to Japan or Okinawa as US military or a civilian employee of the military is eligible to obtain a KA license. For more information, contact FEARL, c/o Sam Flemming, USAGH D/O, APO SF 96343.

That's about it for this month. I hope some of the information provided here will help you pick up a few new ones. If it does, let me know. In the meantime, don't forget we are always looking for DX info and pictures. Any pictures you send us can be returned if you wish. In the meantime, best DX and health.

Thanks as always to the *West Coast DX Bulletin*, LIDXA *Newsletter*, and *WorldRadio Magazine* for much of the preceding information.

Looking West

USER RIGHTS

Question: What rights, if any, do repeater users have when being repeated through the station of another amateur? This is a question being fiercely debated in southern California and elsewhere. It recently surfaced here in Los Angeles when one of the control operators on the WA6KOS/R system turned the repeater off on a system user because of the "content of communications." The operator in question yelled "censorship" and the controversy ensued.

One group feels that the system owner, licensee, or control station does not have the right to turn off the repeater for any reason other than a technical malfunction, and that the repeater is akin to a public utility and therefore must be kept on the air regardless of what is repeated. This group feels that the total responsibility for "content of communications" rests with the individual system user, and the use of jamming, music, and even profanity is left to his discretion. To turn a repeater off under these circumstances is an act of censorship against the originating station.

The other side yells "wrong!" The FCC rules clearly state that an amateur station may not transmit profanity, unidentified signals, or music, and that a repeater does constitute an amateur station. Therefore, not only do the system licensee and control operators have a right to terminate system operation in such circumstances as outlined above, but under the terms of Parts 97.113, 97.115, 97.116, 97.119, 97.123, and 97.125 of the FCC Rules and Regulations, they are directly *obligated* to take such action. To do otherwise directly violates FCC rules. This group also feels that once an amateur decides to operate through a repeater, he is, in effect, operating through the station of another amateur. Therefore, when operating through a repeater, the user gives up any First Amendment rights and is totally subject to the will of the system owner/licensee. Whatever standards, guidelines, and regulations the *licensee* sets for user operation must be adhered to without question.

Where do we find the answers? Part 97? Have any of you read Part 97 lately? The FCC regulations, in relation to repeater operation, are too ambiguous. For that reason, I have written a letter to the FCC asking direct questions about repeater operation, regulatory enforcement, and other related matters. The letter was written on June 19, 1979, and was mailed to the FCC on June 23rd. It is presented below for your information. If received, the FCC's response will also be presented in this column.

Federal Communications Commission
M Street
Washington DC
Attn: Personal Communications Division

Gentlemen:

I wish to ask some specific questions in regard to Part 97 of the Amateur Rules and Regulations, concerning amateur repeater operation.

1) Who is responsible for "content of communications," the system licensee or the system user?

2) If a repeater system owner permits profanity and unidentified transmissions to be "repeated" via his repeater system (while his system is operational under fully automatic remote control), is he legally responsible for the content of such communications? Can he legally censor such communications? Should he?

3) Does the FCC hold any one person legally responsible for "content of communications" and all other aspects of amateur repeater operation?

4) What constitutes an operational amateur repeater—an established repeater, known to the community, or a repeater system that happens to be operating at any given moment?

5) If an established amateur repeater is resting between transmissions and another amateur decides to operate during that time, is the established amateur guilty of jamming when he operates once again, or is the new operator considered responsible for the subsequent jamming?

6) If the conduct of any amateur is considered by his peers to be obnoxious, although he may be technically operating within the regulations of Part 97, can the amateur community, through the Commission, take any legal action to stop said amateur?

7) Why is the Commission unwilling to heed the calls for help from amateurs who are suffering the outrage of willful and malicious interference on both high frequency SSB and VHF FM repeater operations?

8) Is the Commission willing to enforce the terms of Part 97 of the Amateur Rules and Regulations regarding profanity and unidentified transmissions (97.116, 97.119, and 97.123)? If not, why not?

9) Why hasn't the Commission acted to suspend or revoke the amateur license of one Scott Lookholder WB6LHB? He was convicted in federal court on a charge of using foul and abusive language on the two-meter amateur band. I have copies of letters sent to the Commission by southern California amateurs requesting such action. Does the Commission intend to act in this matter?

10) What action can we amateurs take to rid the community of the individuals who, licensed or unlicensed, willfully and maliciously jam, harass, and intimidate the law-abiding amateur's day-to-day operation? Would the Commission be willing to act if supplied documentation of such violations? Exactly what type of documentation does the Commission require before acting on such reported violations?

11) If I challenge the right of another amateur to hold an amateur's license because he operates his amateur station in violation of the regulations as set forth in Part 97, what possible Commission action can be taken? Must I file a formal challenge with your office?

12) Please define the following (using specific examples) as they relate to our subject:

A) willful and malicious interference

B) unidentified transmissions

C) profanity and indecency

I intend to publish this letter—and your response—in my "Looking West" column. Many amateur repeaters are suffering tremendous willful and malicious interference problems, and it is my hope to help guide them toward a solution. Your response to these questions will be appreciated.

Yours truly,
William M. Pasternak

I wish to credit WB2MIC for arousing my interest in this subject. In the June issue of *73*, a letter appeared from Jozef which relates directly to the situation out here. Jozef felt that he was treated unfairly by a repeater licensee who may have arbitrarily censored him. I must state my personal belief that, while I may not agree with arbitrary censorship by control operators and system licensees in certain situations, these people are clearly within their rights when they choose to censor. While you and I may not want to adhere to these standards, we are obligated to do so because we really have no alternative. I remember being told by one amateur that he felt he was a "god" by virtue of the fact that he owned and operated his own repeater. If he demanded that his users "paint their radios with red stripes and operate only while standing on their heads," they had better adhere to his dictates "or else." He had absolutely no compunction whatsoever about turning off his repeater if someone even "sneezed the wrong way." He was clearly "the boss."

It sounds absurd, but that's the way he felt. Having never operated through his system, I cannot tell you how tight a ship he really runs. Jozef and many others are unhappy with this unresolved situation. The problem is spreading. Only the FCC can make a final determination of this matter, and we await their answer.

HANDLING MALICIOUS INTERFERENCE DEPARTMENT

A few months ago, "Looking West" ran a series of articles on the problem of how to deal with malicious interference. While the amount of response to my questions has not been overwhelming, I have received a few letters. Over the next few months, I hope to bring you some of my respondents' views.

The following letter appeared in the June issue of the Mt. Lee (CA) Repeater Association *Newsletter* and is relevant to our discussion:

The jammers must be getting quite a laugh out of repeater users and owners these days, because a lot of us are so easy to bait.

A jammer with nothing better to do will figure out someone's weakness and rub that person the wrong way. Often this jamming is legal, because the one doing the jamming is a ham and uses proper prodecure. The jammer, by manipulating the right people with the right words, can tie up a repeater with hours of counter-jamming, shouting matches, and arguments. Former "good guy" hams, when baited and sufficiently angered, may resort to counter-jamming the original troublemaker. The jammer's gotten what he wants: People have taken his bait. A good example of this might be the licensed ham who uses CW on a repeater. He uses correct procedure, callsigns, and breaks properly, but may be trying to bait a response. CW, RTTY, and SSTV are legal on repeaters if mode and bandwidth rules are obeyed. Instead of reacting with hostility, come back with perfect *F1* 30-wpm telegraphy! What rubs *you* the wrong way? Do *you* fall for the bait?

Some of us feel that high power is

the solution to jamming. Boy, it feels good to talk right over the twerp with your 150 Watts and listen to the capture effect on your duplex! Secretly, you probably hope the jammer also has duplex so that he can hear his puny signal get stomped. Although this is satisfying, it creates problems. With 150 Watts versus the 2 Watts of the jammer, the DF committee will have a hard time hearing the jammer. Many jammers don't care if they are Q-5 into a repeater or not, because they get their jollies causing discomfort to other hams.

"Sorry OM ... no copy ... you're being jammed ... 73." You, the legitimate ham, have just succumbed to a psychological defeat from the jammer. The jammer is laughing at you. Try to sign off gracefully, if you're not succeeding. Don't give him his kicks by going QSY or QRT. Try to draw the jammer out the same way he baits us. Bait the jammer, legally ... don't talk *to* him, talk *about* him to another ham. Don't get into jamming him. Instead, go to low power and allow plenty of time for breaks. It's unpleasant to hear one of these clowns and you may want to "cover" him, but be sure to leave a space for the DF committee to listen in. While drawing out a jammer, it is important not to act as he does. It's easy to get mad and jam the jammer. Aren't we better than that?

Most of us have a local repeater ... a machine we like to hang out on, meet our friends, etc. It is hard to break away from a favorite machine and go somewhere else. We are loyal to the repeater or club to which we belong. When most of us get mad at a jammer, we want to make our stand on our own machine. When the jammer is forced off our repeater or decides to hassle another group, we tend to become temporarily apathetic about our common problem.

Jammers have knobs on *their* radios, although it seems some hams don't ... and these hams should be helping the ham community by following the jammer around the dial. All repeater users should get some sense of community and try to pool personnel and equipment to beat this thing. We must be able to continue the hunt even if the jammers have left "our" repeater and moved to another. The jammers seem secure in knowing that they can change frequencies without other repeater groups following.

DFers already know what to do, and the average user can also help. When the carriers or cursing start, listen to the input to the repeater. Normally, your radio is set so that you are transmitting on 147.84 MHz (the input) and receiving on 147.24 MHz (the output). Reverse this setup, or at least find a way to listen on 147.84. (Transmitting on 147.24 is not necessary.) Now, check your S-meter; is the needle 25% over from 0? 80%? 100%? Break with your call, QTH, cross-streets, time of day, and date, and tell the "woodwork" what % reading you have. See if any other breakers would like to give their reports. (We use % of signal instead of S-units because S-meters are not standard or accurate.)

Let's hope we can end apathy on the airwaves and pool our resources. After all, the jamming is only a by-product of our apathy. The problems on repeaters affect us all, and high-power amps, private systems, and 800-channel radios are not adequate solutions to our common problem.

73,
An Interested User

Review

TELEVISION HANDBOOK FOR THE AMATEUR

A large number of hams are professionals in the field of commercial television. Their daily involvement in the world of video gives them a headstart in understanding and operating a fast scan television station. The rest of the population shouldn't be discouraged, though. The book, *Television Handbook for the Amateur*, is a real help in bridging the gap between beginner and pro.

Television Handbook is published by Aptron Laboratories and a paperback edition costs $6.50. The author, Biagio Presti, is not a ham, but as president of Aptron, he is familiar with amateur television efforts. The first two-thirds of the book is devoted to theory, while the remaining 30 pages discuss construction projects and include tables dealing with radio transmission and television standards.

By minimizing the use of mathematics and including numerous illustrations, the author is able to make the theory chapters down to earth and very understandable. The circuits used to generate a video signal are thoroughly described. To get the most benefit from these chapters, the reader should have a good background in basic transistor circuit design. If you are studying for an Extra class license, the *Television Handbook* may be helpful. Questions concerning television theory appear on some versions of the exam.

There is an abundance of information about special circuits that won't be found in the usual amateur references. Color television may be more of a dream than a reality for most beginning ATVers, but the reader's appetite is whetted by a short summary of the principles involved. The contents of these chapters will be of interest long after your first ATV QSO.

The construction chapters are similar to the theory section. The sub circuits that comprise 450-MHz transmitters and receivers are tackled individually. It is not like the wire-by-wire description frequently found in some ham publications. There is adequate information for the experienced home-brewer. As a bonus, you will have a good understanding of the theory behind the design.

The recent appearance of commercial equipment and beginner-oriented literature has helped to put fast scan television within the reach of many hams. *Television Handbook for the Amateur* does not give complete coverage of the subject, but for a ham who aspires to be more than an appliance operator, it is bound to be useful.

Tim Daniel N8RK/1
Peterborough NH

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

Corrections

In "So You Want to Raise a Tower" (July, 1979, page 110), Photo J shows what appears to be a vertical stacking of the cable lengths under the cable clamps. The cable lengths should be positioned in a horizontal side-by-side arrangement such that both halves of the cable clamps contact each side of each cable.

Gene Smarte WB6TOV/1
News Editor

In reference to "At Last! A Really Simple Speech Processor," June, 1979:

Thanks to W5VSR for pointing out the need for a circuit change. A 10k pot should be added at the emitter of the first transistor.

Sorry about any inconvenience this may have caused.

Jeff Stadelman W9UT
Pound WI

Ham Help

I just acquired an 80-10-meter amp. It's a TXL-80B made by Westcom Engineering. The problem is that the final transistors have been blown and I can't find any suitable replacements, as the transistors have a nonstandard "house number." I'd be grateful to anyone who could suggest a good replacement, or give me an address where I might find Westcom. Thanks in advance for helping.

Bob Howie WA4ZID/9
10432 Baseline Road
Lafayette CO 80026

I'm the president of the newly-formed Phoenix Honeywell Amateur Radio Club and could use some help. We have a lot of tube-type equipment and most of us would like to replace the front-end rf stage with an FET equivalent (such as a 6HA5). We would like to build them on a direct-replacement tube socket. Does anyone have tubes-to-FET conversion circuits? Also, does anyone have any application circuits for FET noise blankers or audio noise filters? Any help will be appreciated.

P.J. Scola, President
Phoenix Honeywell Amateur Radio Club
PO Box 6000
Phoenix AZ 85005

I am in need of a schematic for a Pride 150 bilinear amplifier, 80-10 meters. If anyone has one and could send a copy, it would be a great help.

LETTERS

from page 14

electronics experimenter, though, and guess I must agree with you that, in my experience, your mag is more with it in terms of construction articles than are the official publications of the ARRL. I tuned in too late to know the whole background of your seeming vendetta against this organization, but I suspect that you have some valid points, if only because too many organizations in and out of gov't (plus religions) get hardening of the arteries too soon, after which everyone wants to merely survive and not rock the boat. Being an iconoclast, I'm sympathetic.

Recalling the ARRL "pledge of allegiance," so to speak, that would have the ham saying that he owed his hobby to the ARRL, much as I owe my soul to the company store, I don't think I'd care to be represented by that "religious" denomination even if I were to become a ham.

Beyond that, there was a time when I used to buy the *Handbook* every few years, mainly for new test instrument circuits to build. Then I noted that it was about the last and least source of such information. Now I get the unchanging data I need (like the nice LCR resonance chart) from editions some 10 years old. The formula is still good, but magazines such as yours give me a better update on test instrument circuits, even though I scarcely need your July antenna issue, except maybe for my TV set.

Benjamin Johnson
Rochester NY

ECLECTICISM

It may interest the ham community to know that Sears, after seemingly abandoning ham radio in the Spring-Summer '79 catalog, has jumped back in with both feet.

On pp. 1238-9 of the Fall-Winter '79 catalog, the Sears 22-channel 2m FM xtal rig has returned, grouped with—brace yourself—the Midland (that's right, Midland—not a Sears nameplate in sight) 13-510A 2m syntho rig and the Midland (again!) 13-509 and 13-513 220 (!) FM rigs (xtal and syntho respectively). I'm not going to comment on prices (other than to say that they seem reasonable) because there is a bigger matter which this raises.

I was perusing Looking West in *73* #200 (May, 1977) which touched on the flak raised by Sears' first foray into amateur gear. This increased involvement (especially the 220 rigs) is bound to raise even more, so I thought I'd get my two cents in before inflation struck. At least Sears does point out that you must have a license, although I wish they could get it straight that it's *Technician*, not "Technical." I'm a Tech myself, and I like them to get my class right. What's more, the added exposure of 220 (use it or . . .) can't hurt! As for the bugaboo about "da CBer gonna getcha"—well, if we can't handle a few unauthorized signals (the price of the rigs will keep the CB-boom $39 radio crowd off the band), we are in trouble.

On other matters, keep the mag the way it is (if not better!). Don't be bullied away from the eclecticism, the controversy, and the general free attitude of the magazine! At this time, it's the only ham magazine (counting *Worldradio* as a newspaper) worth reading! Keep it up!!

Edward Eastman WD0ENF
Minneapolis MN

IGNORAMI

I cannot sit idly by any more and let some unintelligent and uneducated hams slash your wonderful magazine and enlightening editorials. I cringe every time someone says that Wayne is against ham radio (WD8DWO, Letters, *73 Magazine*, June, '79). These people must have read his editorials with their dunce caps on! Anyone who digests them with intelligence or has read Wayne's writings for a while can clearly see that Wayne Green is one of the leading proponents of ham radio and that ham radio is one of Wayne's lifetime loves.

I have been reading his editorials since I received my Novice license in September of '75, and while there have been times when I disagreed with Wayne, I have always been impressed with his honesty and his factual unbiased reports of many situations. I admire the way he has never backed down on an issue, nor been afraid to state his opinion on any issue. I also admire the way he has succeeded in his business ventures.

So the next time you read one of Wayne's dynamic editorials, read it intelligently and you will learn about the inside happenings of ham radio, politics, business, and about devotion. I have learned about these things and more from Wayne's editorials, and so even though I know Wayne will not let a few ignorami stop him, count me as one of his supporters and keep those unabashed, interesting, and provocative editorials coming. Your magazine is the best in ham radio and better than most of the others in other fields, so continue the good work and take it easy!

John Kerekes N9EI
South Bend IN

GREEN PAGES

I just received my first *73* issue on a new subscription. The article on "The KGCY Story" was worth the price of the subscription. Keep articles like this coming and I'll renew . . . could do with fewer "green" pages, however.

Ron Schwendt N3AR
Douglassville PA

EGYPTIAN PROGRESS

As the first woman member of the Egyptian Radio Club, Inc., Granite City IL, I feel compelled to respond to the "Letter to the Editor" written by Tania Miller WB9TKC that appeared in the August, 1978, issue of *73 Magazine*. Tania's letter was written as a result of the difficulty experienced by women who wished to become members of the club. At that time there were enough members who did not want women in the club to block any attempt by women to join. Since that time, however, open-minded members have been responsible for changes that allow any responsible amateur radio operator to join the club.

I believe that this progress shows that old traditions and ideas must be changed when they do nothing except cause hurt feelings or give people in control a feeling of power. There is no place in amateur radio for prejudice.

My husband and I have both enjoyed being members of the Egyptian Radio Club very much. We have met and learned from a super bunch of fellow hams. We are pleased with the progress that has been shown in the Egyptian Radio Club, Inc.

Bess J. Nelson WD0CZF
Florissant MO

NUKES

One year ago, I was one of those people who thought nuclear power would really help. I didn't question the authority of the geniuses who gave us Three Mile Island, Brown's Ferry, and the Karen Silkwood cover-up.

Since then I have learned a lot about the poor engineering, short-term monetary greed, and media whitewashing that goes hand in hand with the nuclear industry.

On June 30, I and forty to fifty thousand people were at the Diablo Canyon rally in San Luis Obispo, California. I saw exhibits there on solar and many types of alternative energy—alternatives that have been here for years. There were people from all walks of life there, and even some fellow amateurs.

I believe this is no longer a small minority issue. I feel that we hams should set a good example and use our excellent tinkering and engineering ability to apply to solar and alternative electricity sources.

Let amateurs use solar power at the home QTH, at Field Day, and at outdoor fairs.

Let amateur publications show conscience and responsibility by running how-to articles on alternative energy. Let amateurs, through their global communications capabilities, exchange information on solar and other alternative electric power.

I hope you will take these ideas to heart for technical articles, parts source articles, and editorials. I am one ham who doesn't need "nukes," and I know there will be others.

James G. Coote WB6AAM
Los Angeles CA

CONVERTING

Perhaps this information will be of interest to those of you converting 40-channel CBs to 10 meters. I received a Hy-Gain model 2681 board, less channel switch (which includes rotary dial and knob). I found that Hy-Gain parts are available through Telex Communications, Inc., 8601 Northeast Highway 6, Lincoln NE 68505, Attn: Jim Kepustka.

The parts noted above are listed as: part #700047, switch, $0.75; 40-ch dial, $0.50; channel knob, $0.50; shipping (very good box), $1.00.

The board is sold by Poly Paks, and costs about $12.00. They will supply a schematic diagram (specifically request it). Other info is supplied but it does not have much to do with the board received. It does give

info on another type of PLL which may or may not be used in another board they can furnish for more money. A complete Hy-Gain 40-channel set with all controls on the mike is available; the mike is an extra.

I haven't yet seen an SSB rig on sale through any of my contacts for less than $65. One should be available soon, as the popularity of CB in the crowded cities is going down fast.

The big surprise is that the going price for a divider-type switch used with other rigs seems to be from $16 to $25. I get that from the CB repairmen, who say that they practically never have to replace them. Look at the price I paid for it (75 cents). When I figured out how to build a switch to divide by 278 or so, I thought $20 was pretty fair.

Henry B. Plant W6DKZ
San Jose CA

CLASSICS

Being a Novice of about three months, I find my subscription to *73* thoroughly satisfying and enlightening in all aspects. It is very gratifying to have a publication on our behalf that pulls no punches and has its cards laid out on the table instead of putting up a smoke screen and being cloaked with the "official final authority" attitude approach. In your June issue (#225, page 13) Letters department, Don Hurley VE3HAN suggested an "equipment evaluation" booklet of rigs dating back over the past twenty years. Sounds like a great idea. Obviously an enormous amount of time and effort would need to be put into a big project on that order. Consider, though, how much value such a reference-type booklet like that could be . . . it would be ideal to bring along to that next hamfest for when you're rummaging through those tables of used Hallicrafters, Hammarlunds, Johnsons, Nationals, etc. If an "equipment evaluation" booklet is not conceivable, then how about running a feature article in *73* on some of those more popular older classic rigs?

Speaking of so-called outdated gear, if you tune around the bands listening carefully, there are plenty out there sporting their well-maintained vintage equipment . . . just another facet of the art. I run those "oldies but goodies," a Viking Valiant I transmitter with a Hammarlund HQ-100 receiver. Keep up the superb work.

Bill Wolf KA2EEV
Newark NJ

FEARL

Any hams working in the military or for the military services as civilians should definitely bring their gear along on permanent changes of station to Japan. Write to FEARL, c/o Sam Fleming KA2SF, USAGH D10, APO SF 96343, or call 228-4703 (military number in Japan) for info. Licensing is done by US Forces, Japan. All US license classes get full privileges, except that no mobile portable operation is allowed (except MARS, where we have 2m frequencies and repeaters, etc.).

SFC W. J. Graham KA2WG
Signal Act-N
APO SF 96343

OLDIE

I would like to comment on your review concerning the Daiwa CN-720 swr and rf power meter (June, page 24). Your statement, ". . . why someone didn't think of it before . . ." left me bewildered.

On page 386 of the September, 1952, issue of *DL-QTC*—yes, 1952—G. Blaeser DL1GX describes a standing-wave indicator which uses a cross-pointer instrument similar to the one used in the CN-720.

DL1GX's work was based on the work of a Mr. Buschbeck. Mr. Buschbeck's idea and invention was published in Volume 61, April, 1943, of *Hochfrequenztechnik und Elektroakustik,*" decimal classification DK 621.717; 621.396.61.

In the June issue of the *Technical Library* of the Northwest German Radio Network, 1949, Dr. Roland Walter describes this type of instrument again because, due to the war, most of the original material got lost or was destroyed.

Telefunken marketed a version for use on high-power BC and shortwave transmitters in the early 50s, with power handling capacities of up to 100 kW. It was called "supervisory equipment for feedlines for short, medium, and long waves." It became a standard on all major transmitting equipment in DL-land.

Ergo, the idea of the cross-pointer instrument in the context of swr measurements is about 36 years old.

Kurt U. Grey VE2UG
Sept Iles, Quebec

MISS AMERICA

This is to advise of the following station activity: Special Event—Miss America Pageant, Atlantic City, New Jersey. Station K2BR will be operating from the Miss America Pageant Headquarters in Atlantic City NJ, September first through eighth, 1979. It will be sponsored by the Southern Counties Amateur Radio Association (SCARA). Approximate frequencies: CW—3560, 7060, 14060, 21060; Novice—3730, 7130, 21130; Phone—3935, 7235, 14280, 21380. QSL to K2BR, 591 White Horse Pike, Egg Harbor NJ 08215 (SASE, please). Traffic to and from the Miss America contestants will be accepted.

Henry G. Rainville K2HG
Miss America Pageant/
SCARA coordinator
Ventnor NJ

HAMMARLUND

I have been trying hard to find a replacement variable tuning capacitor for my Hammarlund HQ-170A VHF receiver and finally found one at Pax Mfg., 100 Montauk Hwy., Linden Hurst NY 11757, (516)-884-4300.

In talking with Mr. Peter Kjeldsen of Pax Mfg., he indicated that they have most replacements for Hammarlund capacitors. Maybe this information will help someone else find parts.

Leroy Marion W8CGQ
Marlette MI

JAMMING

As printed in "Letters" of the June, 1979, issue of *73*, reader K6EGM is ". . . appalled that you could publish something ("The 2-Meter ECM Caper," *73*, February, 1979) tantamount to sanctioning the jamming of another station . . ." and says that such "new" ideas are not in the best interest of amateur radio.

Apparently K6EGM is not well versed in the history and romance of amateur radio. "Jamming," intentional, accidental, or fantasized, is not a "new" idea. It has been going on for over 50 years in every and any call area.

I suggest that K6EGM read "The Templeton Case" by K9ODE which appeared in the January, 1963, issue of *QST* magazine.

Byron H. Kretzman W2JTP
Huntington NY

New Products

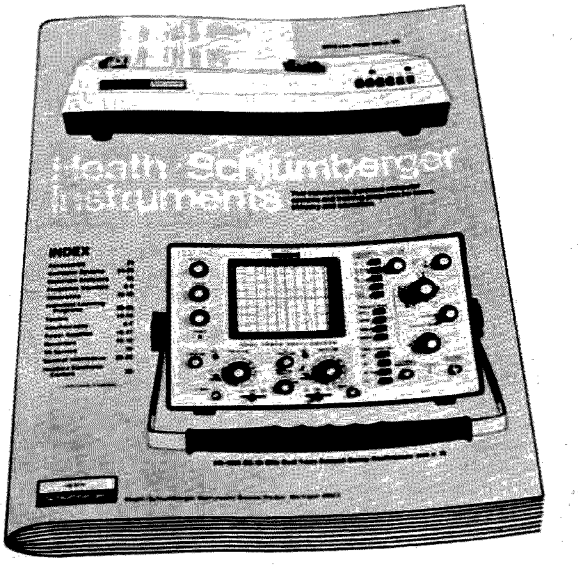
from page 40

The new pocket scanner features sturdy construction, with an anodized aluminum front panel to withstand demanding on-the-go use. A flexible "rubber ducky" antenna is supplied, but the radio can also be used with a wire antenna. The radio can be operated from external power, as well as from internal batteries. Also contributing to the radio's versatility are provisions for plugging in an external battery charger, headphone, and external speaker. For further information, contact *Electra Company, PO Box 29243, Cumberland IN 46229.* Reader Service number E40.

TRAC CMOS ELECTRONIC KEYER

TRAC's Model TE133 keyer.

TRAC Electronics, Inc., has introduced an addition to its line of state-of-the-art CMOS keyers. The TRAC CMOS Electronic Keyer, Model TE133, contains all CMOS integrated circuitry. Included features are self-completing dots and dashes; both dot and dash memory; iambic keying with any squeeze paddle; 5-50 wpm; speed, volume, tune, and weight controls; and built-in sidetone and speaker. Low-current-drain CMOS allows portable battery



Heath/Schlumberger's new catalog.

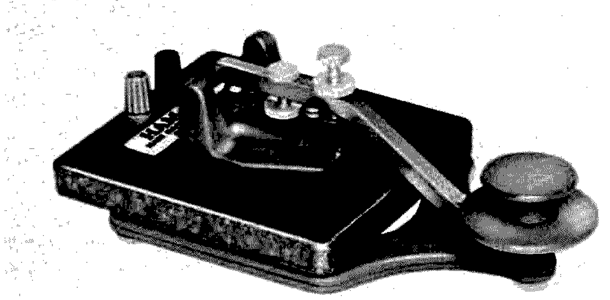
operation. The rear panel contains deluxe quarter-inch jacks for output and keying. The TE133 CMOS Electronic Keyer is operated on a single 9-volt battery and keys both positive and negative keyed rigs. For further information, contact *TRAC Electronics, Inc., 1106 Rand Building, Buffalo NY 14203.* Reader Service number T18.

HEATH/SCHLUMBERGER OFFERS LATEST INSTRUMENTS CATALOG

Heath/Schlumberger has announced the publication of its latest instruments catalog. This new catalog features Heath/Schlumberger's complete line of fully assembled and tested computers and peripherals and gives complete descriptions and specifications for their line of electronic test instruments. Included are oscilloscopes, laboratory-grade strip and X-Y recorders, power supplies, various signal and function generators, counters, and a full line of multimeters (from analog to digital).

In addition, the publication contains a complete listing of Heath/Schlumberger Continuing Education Programs for industrial training, including ac and dc electronics, semiconductor devices, digital techniques, microprocessors, and test instruments.

For further information, contact *Heath/Schlumberger, Dept. 350-870, Benton Harbor MI 49022.* Reader Service number H5.



Ham Radio Center's HK-3M.

THE HK-3M KEY

Ham Radio Center has introduced a new modified straight key which replaces their popular Model HK-3 Ham-Key™. The new model is the HK-3M; it features a new anti-tip bracket that defies even a pump-handle type of operator from tipping over. The beauty of this new feature is that any HK-3 now in the field can be converted to an HK-3M by merely adding the easily-installed AT-B bracket.

For further information, contact *Ham Radio Center, PO Box 28271, St. Louis MO 63132.* Reader Service number H2.

Ham Help

I would like a schematic and input/output impedance for an RME 80-10 preselector. The model is unknown, but I think it matched the RME 6900 receiver. Thanks.

William F. Mollenhauer N2FZ
Box 3, RFD 1
Glassboro NJ 08028

I would like to receive schematics for any modifications to the Ten-Tec PM2/2A QRP rig.

H. Goldberg VE3JBU
PO Box 913, Stn. B
Ottawa, Ontario
Canada K1P 5P9

I would like to get in touch with amateurs who believe in UFOs, who have made a sighting or who are members of any organization that investigates UFOs. I would to like to organize an international net.

Anastasios Panos SV1IG
PO Box 2563
Athens, Greece

I got a flood of replies to my request in the June issue. Thanks a lot, fellows! Instead of a brief visit in August, I have decided to come on the "HOUSA" student exchange/work scheme from November, 1979, to February, 1980. Under this scheme, NZ students can come to the US or Canada to work and sightsee.

Ideally, I would like to work for short periods in various parts of the US, and would appreciate information on temporary jobs and accommodations.

I would also like to hear about UHF FM repeaters, as I intend bringing along my home-brew mobile rig (cheap, but good), based on our club design. Do UHF repeaters need the special access techniques, e.g., tone burst, etc., like your 2-meter ones?

Ash Nallawalla ZL4TBU
PO Box 6159
Dunedin, New Zealand

I have been following the articles on the conversion of CB sets to 10 meters and I have been trying to convert a SBE Sidebander II mobile rig, but have run into problems.

Does anyone have any information on the conversion of this unit? I did find the article on the SBE Sidebander III model (January, 1979, *73*), which is strictly sideband (no AM) and am told that the boards are entirely different.

I have changed the base crystals up 1.535 MHz to put channel 1 on 28.500, but, after complete alignment, which makes the set very hot on both receive and transmit, we find ourselves on a *lower* frequency than even 11 meters. Around 25.535.

James W. Barnes WB7PKR
PO Box 283
Mesa AZ 85201

I need a schematic or conversion info on an ARC R-19 aircraft receiver which tunes 118-148 MHz. Expenses will be reimbursed.

Howard S. Robb AFØW
Box 17
Bird Island MN 55310

I need a manual, or a copy, for a Gonset G-76 transceiver. I will pay costs.

Tim Rulon WA2KQD

MEMPHIS TN
OCT 13-14

The Mid-South Amateur Radio Association and participating Memphis-area clubs will sponsor the Memphis Hamfest and Tennessee State ARRL Convention on October 13-14, 1979, at the Youth Building at the Mid-South Fairgrounds, Memphis, Tennessee. Featured will be forums, exhibits, a giant flea market, FCC exams, a hospitality party, and commercial and manufacturer exhibits. The display area will be open from 9:00 am to 4:00 pm on Saturday, and from 9:00 am to 2:30 pm on Sunday. Fifty trailer hookups are on the premises, which the Memphis Park Commission will rent for $5.00 per night.

BEAVER OK
OCT 14

The Beaver Hamfest will be held on October 14, 1979, at the Fairgrounds Building in Beaver OK. Doors open at 8:00 am, with registration at 10:00 am. Tickets are $2.50 each. There will be a covered-dish luncheon, a short program at 1:30 pm, swap tables, and door prizes. Camper hookups are nearby and the event is airport-close. Talk-in on .01/.61 and .52. For details, contact Stella Shaw WB5VUN, Box 310, Beaver OK 73932, (405)-625-3368.

LIMA OH
OCT 14

The Northwest Ohio Amateur Radio Club will hold its annual hamfest on October 14, 1979, at the Allen County Fairgrounds, Lima, Ohio. Two large heated buildings will house the hamfest where tables will be available for $3.00 each. A flea market will be held outside for free. Advance tickets are $2.00 each. For information, send an SASE to NOARC, PO Box 211, Lima OH 45802.

WEST GHENT NY
OCT 14

The Northeastern States 160-Meter Amateur Radio Association will hold its annual election and banquet on Sunday, October 14, 1979, at Kozel's Restaurant, Rte. 9H, West Ghent, New York. There will be a flea market in the rear parking lot at 1:00 pm and a roast beef dinner at 5:00 pm. All hams and XYLs are welcome. For reservations and details, contact William Derby WA5IOD, Secretary/Treasurer, 14 Plain St., Medfield MA 02052.

ISLIP LI NY
OCT 14

The Long Island Mobile Amateur Radio Club, Inc., will hold its Hamfair '79 on Sunday, October 14, 1979, from 9:00 am until 4:00 pm at the Islip Speedway, Rte. 111 (Islip Ave.), one block south of Southern State Pkwy., Exit 43, or come south from the Long Island Expressway, Exit 56, Islip, Long Island, New York. There will be free parking, door prizes, and several contests. Admission is $1.50 (non-hams are free) and $3.00 per seller's space, which permits one person to enter. For information, call Hank Wener WB2ALW, nights, at (516)-484-4322, or Sid Grossman N2AOI, nights, at (516)-681-2194.

ANAHEIM CA
OCT 19-21

The ARRL Southwestern Division Convention will be held on October 19-21, 1979, at the Sheraton-Anaheim Hotel, located at Ball Rd. and I-5, Anaheim, California. The convention will begin on Friday evening with registration and exhibits from 4:00 pm until 9:00 pm. On Saturday, registration will begin at 8:00 am and exhibits and technical sessions will run from 9:00 am until 3:30 pm. FCC testing will continue until 3:30 pm also. The ARRL Forum will be held from 4:00 pm until 5:30 pm, with a no-host cocktail party being held until the 7:30 pm banquet. The Wouff Hong pageant will be held at 00:01 am PST on Sunday morning. At 9:00 am Sunday morning the various breakfasts will be held and the exhibits will again be open until noon. The preregistration deadline is September 15, 1979. Advanced registration price, which includes complete program, banquet, exhibits, and technical sessions, is $17.00, and $19.00 at the door. The charge for the banquet only is $12.00, and for exhibits and technical sessions, the charge is $5.00, pre-registration; $6.00 at the door. The ladies' program and luncheon is $6.00, preregistration only. For more Information and pre-registration, contact Hamcon, PO Box 1227, Placentia CA, or phone (714)-993-7140.

CEDAR RAPIDS IA
OCT 19-21

The 1979 ARRL Midwest Division Convention and CVARC Hamfest will be held on October 19-21, 1979, at the Five Seasons Center, Cedar Rapids, Iowa. Tickets are $4.00 in advance or $5.00 at the door. Forums will include FCC, ARRL, DX, antenna, AMSAT/OSCAR, FM and repeaters, microprocessors, modern CW, and more. A flea market will be held at $5.00 per table with 150 tables available. Reservations are good for Saturday and Sunday and must be paid in advance. Pre-registrations will be taken through October 1, 1979. Setup begins at 6:00 am Saturday. FCC exams also will be given on Saturday. (Send Form 610 and copy of license two weeks in advance.) There will be many prizes, including a grand prize of a deluxe HF transceiver, a TH6DXX antenna, a HAM III rotor, and a 60-ft Rohn 25G tower. There will be a Saturday-evening banquet, with Senator Barry Goldwater K7UGA as guest speaker. There are many hotels and motels available. Talk-in on 146.34/.94. For information, write Convention, Cedar Valley Amateur Radio Club, Box 994, Cedar Rapids IA 52406.

BILOXI MS
OCT 20-21

The Gulf Coast Ham/Swap Fest will be held on Saturday and Sunday, October 20 and 21, 1979, at the International Plaza, located at the west end of the Biloxi-Ocean Springs bridge on Highway 90 In Biloxi MS. Tables are $3 per day or $5 per weekend. Talk-in on 146.13/73 and 146.52. For information, advance tickets, and tables, contact Al Williams WD5GNR, 311½ DeMontluzin Ave., Bay St. Louis MS 39520.

READING MA
OCT 20

The Quannapowitt Radio Association will hold its annual auction on October 20, 1979, at the Knights of Columbus Hall in Reading, Massachusetts. Doors will open at 10:00 am and the auction will start at 11:00 am. Food and refreshments will be available. Talk-in on 146.52. For information, call Bob Reiser AA1M at (617)-272-6219.

NORFOLK VA
OCT 20-21

The fourth annual Tidewater Hamfest-Computer Show-Flea Market will be held on October 20-21, 1979, starting at 9:00 am at the Norfolk, Virginia, Cultural and Convention Center SCOPE, Norfolk, Virginia. There will be 60,000 square feet of air-conditioned exhibit and flea market tailgating space available. Featured will be ARRL meetings, DX and traffic forums, and a CW contest. FCC exams are planned for amateur upgrading on Saturday from 9:00 to 12:00 am. A special feature will be a dinner cruise and banquet on the *Spirit of Norfolk* cruise ship on Saturday night for $16 per person, or $30 per couple. Advance registrations are $2.50 (include an SASE) or $3.50 at the door. Flea market tailgate spaces are $3.00 per day. For tickets and information, write TRC, PO Box 7101, Portsmouth VA 23707.

LONDON ONT CAN
OCT 28

The London Amateur Radio Club will hold its 2nd annual Swap and Shop on October 28, 1979, from 8:00 am until 4:00 pm at Lord Dorchester High School in Dorchester, just off 401. Admission and tables are both $2.00. Featured will be displays and prizes. Talk-in on .78/.18. For more information, write VE3CSK, RR #1, Ailsa Craig, Ontario, Canada N0M 1A0.

FRAMINGHAM MA
NOV 11

The Framingham Area Radio Association will hold its Indoor electronic flea market on Sunday, November 11, 1979, from 10:00 am until 2:00 pm at the Framingham Police drill shed behind the police station, Framingham, Massachusetts. From Rte. 9, take Rte. 126 south to the center of Framingham. Sellers' setup time is from 9:00 am to 10:00 am. Advance table reservations will be $5.00, with tables available at the door for $7.50. Refreshments will be served outside the flea market area. Talk-in on .75/.15 and .52. For information or reservations, write Framingham Area Radio Association, PO Box 3005, Framingham MA 01701.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

GLORY-SEEKING

Having failed to make contact between Pack Monadnock mountain in New Hampshire and the WA1KPS DXpedition to New York State on 10 GHz, it appeared that sterner measures would be necessary. The Pack is a 2,500-foot mountain and has the benefit of a road going right to the summit. The only problems with that are the surprising cold and wind which can strike even on relatively warm days . . . and the pesky little black flies which can make a hot, windless day wretched. These tiny but persistent devils get into your hair, crawl up your sleeves and into your shirt, and BITE!

Not far from the Pack is Grand Monadnock mountain, reaching up 3,500 feet. Since this one has to be climbed on foot, it is nowhere near as popular as the Pack. But, with six states already contacted on 10 GHz and with all contacts being over a path of at least 50 miles, I reluctantly agreed to take an expedition up in the interests of science and a world record . . . Guinness, please note.

Tim N8RK/1, Sherry, and I struggled up Grand Monadnock the previous Sunday in order to make the Connecticut to New Hampshire contact. It took us about two hours to scramble up the 2½-mile path of rock, but at least we were rewarded by getting a nice signal report over that path. Chuck Martin of Tufts Electronics was on the other end with Steve Murray K1KEC and Eric Williams WA1HON. On the second trip, I was able to talk Tim into going again, but Sherry had more sense and she passed up the great event. Jim Grubb WB1AFC, who works for Chuck, drove up from Boston and helped us cart the equipment up the mountain.

We'd just taken along a barefoot Gunnplexer for the Connecticut contact. That was small enough to fit in a knapsack, so it was easy to carry. The signals from that unit had not been overpowering, so we decided this time to take along some insurance in the form of a two-foot dish and a tripod. That was a bit more formidable to haul up the rocky path. Some of the rocks are *big*.

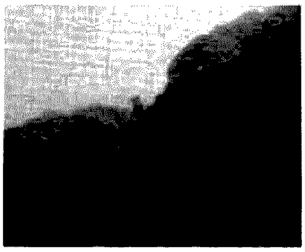
Sunday arrived and the three of us headed for the mountain, talking with Chuck and his DXpedition to New York via the Mt. Greylock repeater. To say that I was not enthusiastic about the climb would be quite an understatement. My normal exercise is to walk from my desk to the kitchen and back for a meal . . . maybe 100 feet total . . . three times a day. Then, exhausted from this, I stagger 20 feet more and up a flight of stairs to my apartment to rest. Typing my editorials strengthens little more than the outrage level in Newington.

Nothing short of the prospect of achieving an almost unbeatable world record of seven states worked on 10 GHz could have gotten me a second time onto that accursed trail up Monadnock. My knees had finally stopped making me limp a day or two earlier, and here I was about to insult them again with another struggle up the endless rocks, although I suppose that two and a half miles of stairs would pretty much do a person in, too. And on the way down, while you don't have your knees pulling your weight up, they do have to take shock after shock as you jump down one to two feet at a time.

The day was warm and very damp. A dense cloud sat over the entire mountain, dripping now and then and threatening to dump rain on us at any moment. We had HTs along for both 146 and 220 MHz and we kept track of downpours which were just a few miles away as we huffed and puffed our way up . . . the sweat pouring off. I'd lost three pounds the Sunday before, and only by virtue of really diligent eating had I managed to regain my fighting weight in time for this ordeal.

The top part of the mountain is all rock. Fires a hundred years or so ago had cleared the trees and shrubbery and allowed the dirt to be washed away, making the mountain one of the most accessible with ecological characteristics that normally are found only above the tree line of other mountains. Naturalists apparently travel hundreds of miles to scramble up these rocks and dote on amazing ecology. I just sweated on it as I climbed. The top part was cooler as we got out of the trees, and there was no protection from the wind. It felt wonderful . . . even in the dense fog.

Just to convince you that when I say rocks, I mean rocks . . . here is what they call a "trail." It's foggy, and you can't see more than about 50 feet.



Perhaps you can make out Tim with the disk on his back, disappearing into the fog. Just to the left is Jim, bringing the tripod on his back. I brought a camera plus my most prized possession . . . me.

Eventually we made it to the top, and here are Tim and Jim setting up the 10-GHz system. The two HTs at the bottom left provided us with communications with the New York contingent . . . Chuck, Eric, and Steve, in the Taconic Range of the Berkshire Hills, some 30 miles east of Albany.

Tim is looking around for a flat spot to set up the tripod and dish, a place with a view to the west *and* New York, hopefully. This brought up the question of which way was west. There is a compass rose painted on the top of the mountain, but it was almost 100 feet from where we were setting up, so we had to sort-of relay the correct bearing through the fog to aim the dish from Jim, standing at the rose, to Tim, halfway between, and me at the site. A passing climber lent us a compass just to check out the dish heading, and we'd come very close.

We got set up a little bit before Chuck and the others reached their hill in New York, so we sat and cooled off a bit, resting. When Chuck was finally set up, we put on the headset and crossed our fingers. Would the whole trip be for nothing? There was no way in the world they would get me to go through that ordeal a third time; whether we made it or not, this was the one and only try . . . so it had better work. Our topographical maps indicated that it was very chancy. Maps of the horizon from the top of Monadnock didn't give us much hope. The signals on 220 MHz, usually a very good indicator of a line-of-sight path, were marginal. I had to hold the HT just in the right spot to make contact. Two meters was a bit better, working on a direct simplex channel.

The moment arrived . . . Chuck finally had his unit, with a four-foot dish, set up and ready to go. We both turned on the switches at the same time and the signal-strength needle swung right off scale . . . whoopee, we'd made it! Now what do you talk about on a solid and very private path like that? After a round of "Come here, Watson, I need you" and some swinging of the dishes to peak the signals, we called it a day and packed up for the trip back home.

The only incident of note was about halfway back down when Jim slid on a rock and went head over heels, landing on his pack on another rock. The only damage was a ruined canteen, which was better than a busted back. My knees hurt only a day or two after the ordeal this time, so I suppose that I might be able to make the climb with no strain if I kept at it for a few more weeks. Don't worry, I won't. And I wasn't nearly as tired this time as the week before . . . hmm. It's too bad exercise takes so much time and is so little fun.

If any of you happen to see Chuck, you might congratulate him on having the world record for working one state from the most other states. I remain the only human being who has worked seven different states from New Hampshire, and I'll bet I will hold that record for a while.

DONATE

The question of ARRL finances seems to get murkier all the time. We see letters crying for donations and we read about the horrible losses they are sustaining with their staff, with few old-timers left and empty offices everywhere . . . offices which were just recently built at enormous expense.

The donations for their WARC efforts are particularly difficult to justify. Noel Eaton testified before the manufacturers that they have over $600,000 available, if they wish to spend it. In addition to that rather tidy sum, I see by the latest Annual Report that they still have kept up their $100,000 fund for the defense of amateur frequencies . . . and WARC would seem to qualify in this department.

Now, it is entirely possible that the League is intending to spend more than $750,000 at Geneva this year. If their perfor-

WORLD'S BEST JOB

How would you like to spend your time setting up and operating all of the latest ham gear . . . and getting paid for it? We at *73 Magazine* are searching for a good technician to come to Peterborough, New Hampshire, and work in the *73* ham shack. We want someone capable of installing, repairing, and evaluating equipment, and generally keeping things in good working order. Some writing ability is also desirable, since we'll want equipment reviews for *73*.

All in all, this is probably the world's best job for an active and curious ham. When you're not erecting a new tower or troubleshooting a balky linear, you'll find that Peterborough is one of the best DX and contest locations anywhere. If we can hear 'em, we can work 'em . . . and we hear 'em all. New Hampshire also offers other advantages, such as no state sales or income taxes.

If you can handle the job and don't smoke, drop us a line—tell us about yourself. Write to: *73 Magazine*, Opportunity of a Lifetime Dept., Peterborough NH 03458. Attention: Jeff DeTray WB8BTH.

Newhall CA 91321

I have yet to hear from the FCC in answer to the questionnaire I mailed to them in May (reprinted here in the August column). I didn't expect a quick response, but two and a half months ago isn't exactly yesterday. Wheels in Washington move rather slowly as we all know, and in the meantime, the malicious interference problem out here grows worse. I suspect that it may be the same elsewhere; my mail seems to indicate this from time to time. Anyhow, when and if the FCC ever gets around to answering, I will quickly share the information with you.

The ARRL has formed the ECRBA! What's that, you say? The ARRL did *what*? I suspect that some clarification is necessary. The "ARRL" I am speaking about is *not* the Newington, Connecticut, variety, but an organization known as the *Atlantic Region Repeater Legion*. (Isn't that a great play on a set of logo letters!) This "ARRL" has now sprouted the east coast's first organized remote-base owners' organization, entitled aptly, the East Coast Remote Base Association (ECRBA). Founded on May 26, 1979, the ECRBA currently has about a half-dozen member systems, with more joining each month.

Unlike its west coast counterpart, SCRRBA, the ECRBA does not act as a frequency coordination council and does not assign systems to specific channels. In the areas in which their member systems operate, such activities are the domain of established frequency coordination councils such as TSARC. Its main purpose is to act as an affiliation of, and thereby a voice for, individual amateurs and amateur clubs along the eastern seaboard who either now operate or are interested in the construction of amateur remote-base stations.

It was to that end that the ECRBA established the following goals for itself:

1) The promotion and support of current remote-base technology and activity.

2) The designation of simplex frequencies on VHF and UHF amateur bands upon which remote-base systems can meet.

3) The coordination and filing of existing remote-base systems in geographically diverse areas along the eastern seaboard so that communications over long distances can be achieved through the creation of remote-base networks.

4) Such other purposes as may later be defined by the ECRBA membership.

The ECRBA appears to be the first such organization to be formed outside the far western and southwestern United States whose avowed purpose is fostering interest and expansion of remote-base operation. If you want more information, send an SASE to the East Coast Remote Base Association, c/o Atlantic Region Repeater Legion, 333 West 57 St., #306, New York NY 10019. For your efforts, you will receive an information sheet and an application for membership.

THE INTERTIE DEPARTMENT, OR "IT'S TIME FOR A REAL GAME PLAN"

How many repeaters are there? 1,000? 3,000, possibly? Experts peg the number of repeaters operational in the continental USA at close to 5,000, with over 3,000 of them on two meters alone! Let's face it. That's a heck of a lot of rf hardware sitting atop tall buildings, broadcast towers, and mountaintops. What do we do with most of it? By and large we use it simply to gab a bit further than we could without such relay devices. In doing so, we miss one of the greatest communication challenges ever placed at our fingertips. The challenge? The creation of a coast-to-coast, border-to-border VHF intertie. An intertie that would permit amateurs from all over the nation to converse and communicate with but handheld transceivers.

With all this hardware operational already, why has such an intertie not yet been developed? Was not one of our greatest objectives in overturning the results of Docket 18803 to permit restoration of intercommunity relay communication and again permit repeaters to interlink for greater range? What have we done with this freedom we gained a few short years ago? Little! True, there have been a number of regional and interregional experimental interlinks, most, if not all, privately owned and operated with highly restricted access and usership. The few local open interties are a minority within a minority. The potential exists, the equipment is there already, and with the addition of a bit more human communication, a national system could come into being within a year or two.

The key to the establishment of an open national intertie is to set our goal and then utilize what we already have. At the outset, a national organization to oversee the implementation of such an intertie is not necessary, although it could make the job a whole lot easier. Once off the ground, such an organization, filled with many layers of bureaucracy that are the byword of such organizations, will develop. Who knows, if we do a good enough job, the American Radio Relay League may even take all the credit for it. Right now, though, we must begin in as simple a way as we can, building outward from the local level.

You might start by locating another repeater in your area some distance away and arrange some form of permanent interlink between the two. Then add a third system in the same or another direction. Exactly where you wind up, geographically speaking, is not that important. Communicating with one another outside the normal coverage area of your favorite repeater is. If enough systems jump on this bandwagon, and if normal growth patterns prevail here as they have in repeater operation development itself, then a national open intertie can and will develop of its own accord.

What's nice about doing it in this way is that we need not add any new systems to the already overcrowded two-meter spectrum. The radio links can be on 420 MHz or, in areas where 420 to 450 is already totally utilized, the 220-MHz band would be an ideal choice. Even in areas where UHF is overflowing with activity, in most cases the 220 MHz band lies dormant. Can you think of a better use for 220 MHz?

There is another important prerequisite. For this idea to work, each area has to know what the next area is doing. To that end, "Looking West" could provide the space necessary to disseminate information. I can act as an informational clearinghouse and thereby give you monthly updates of who is accomplishing what, where. How about it? Does the idea of such a national intertie intrigue you? Do you find interesting the idea of driving in downtown Chicago while conversing on VHF with two friends many thousands of miles away?

At the very close of Dave Bell's new film, "The World Of Amateur Radio," the film's narrator, Roy Neal K6DUE, states: "We look forward to the day that members of our fraternity will be going into space, to the moon and beyond." Maybe for the moment this is but a dream of the future, but when Art Gentry W6MEP placed K6MYK (now WR6ABN) on the air back in the 1950s, I'll bet that he had no idea where it would all lead. Art had made one of his dreams come true, and out of early experiments such as K6MYK grew the VHF and UHF relay activity we have today. In reality, we have far more repeaters in more places than we know what to do with. Many lie dormant day after day awaiting some form of utilization. We have at our fingertips the ability to make the future part of the present. Any dreamers out there? Any takers?

THE VIDEOTAPE DEPARTMENT

A few months ago, I purchased a truly great toy of the 70s. It's called a Sony Betamax videocassette recorder-player and it has brought me many hours of joy. It sits comfortably in a special cabinet in our living room just below our Sony 19" Trinitron color TV, and it gets quite a bit of use, especially with my busy schedule. Originally, it was the "time-shift" feature that caused me to purchase it: the ability to be elsewhere and yet not miss something I wanted to see. Of late, though, I have come to see other uses for my toy, uses that transform it from the toy category into a useful tool—one that can be applied to amateur radio. First, however, let's take a look at what is available in home video recording equipment today.

The Sony Corporation really started what would lead to the home video revolution back in 1968 when it introduced in the US marketplace a video machine that used ¾" tape packaged in a convenient-to-use, fully-enclosed tape cassette. The unit was called the U-Matic, and it was not long before it became a standard in the broadcast industry. While it was not as good as 2" high-band quad, it gave excellent results and soon began to nudge film from the limelight in news gathering and dissemination. By the early 70s, with the advent of the portable videocassette recorder-player along with light-weight (by comparison) cameras, what is now called the "electronic news gathering" or "electronic journalism" era had begun. Today, the majority of news we see on TV is on videotape rather than film.

For consumers like us, things lagged behind. Only the truly affluent could afford a U-Matic type machine. Tape cassettes were rather expensive and offered but one-hour record-play time. However, Sony foresaw the coming video revolution, and around 1975 it introduced its first ½" format home videocassette system to which it

DX

Chuck Stuart N5KC
5115 Menefee Drive
Dallas TX 75227

These are the heydays of DXing. If it seems like we keep repeating ourselves on this subject, bear in mind that we only want to make you aware that this is not the normal state of things. We are now at the peak of cycle 21, and, although there are many good days ahead for the deserving DXer, we are now on the downhill slide. Work everything in sight; those QSL cards will help you make it through the doldrums ahead. Hopefully some of the following information will help you in your quest.

HEARD ON THE BAND

VR3AH left Christmas Island July 22 and returned to the states. VR3AR plans to remain active until February or March and there is a new operator there waiting only for the necessary license to begin operating. There is a possibility that Greg WB4PRU will handle the QSLs for this new station. During the period May 28, 1979, to July 8, 1979, while Doug VR3AH was in the states for a little R & R, Slim paid a visit to his station and managed a number of QSOs. If you logged VR3AH during this period, know that you have met the Slim one himself.

Jerry WA1ZXF sent in the following in response to our request for more CW activity reports. It covers a typical night on 20 meters and while nothing super rare is covered, it shows there is plenty of "bread and butter" DX there for the taking.

FC9UC—On regularly from 1700 to 1900 UTC between 1410 kHz and 14160 kHz. Jean is always happy to answer a CW call.

UK2GAT—A club station operated by the various members. On nightly from 2300 UTC between 14050 kHz and 14070 kHz with a strong signal.

YU2CAL—Mladen is a nightly regular around 14030 kHz.

SP8RJ—Another almost nightly regular. Jurek puts a strong signal into the states around 14035 kHz.

LZ1GC—Stan is on nightly from 0400 UTC around 14070 kHz.

Jerry says there are many more such stations available nightly for the deserving DXer.

EA6DD, formerly EA3EG, shown with his nice station in Palma in the Balearic Islands. Eighty years young and still going strong, he prefers CW and can usually be found on the low end of fifteen or twenty when the band is open.

The second annual International Island DX Contest sponsored by the Whidbey Island DX Association begins at 0000Z on January 12, 1980, and runs through 2400Z January 13, 1980. This is a good chance to pick up some of the rarer islands for *your* DXCC. Contest entry forms are available from Gary Pierson WA7GVM, Box C, LaConner WA 98257.

Roy W5VJT reports receiving QSL cards from UC2AF, UC2AFA, and UC2AFB. UC2AF is father to UC2AFA and UC2AFB.

CK2CRS was the official station of the Canoe/Kayak World Championship. QSL to Serge Freve VE2FIT, 1505 des Martinets, Chicoutimi, Quebec G7H 5X9, Canada.

Jean Ghys, formerly ON4KU, reports that Slim seems to have taken a liking to his old call because he has been receiving a number of QSLs for stateside contacts he never made. Jean says he is no longer active and that any contacts with anyone signing ON4KU are bogus.

We received numerous responses to our comments concerning the trend towards DXpeditions spreading the calling stations out over a 40 to 50 kHz portion of the band, thereby making it useless for any normal use. Those defending such operations pointed to the fact that this method resulted in the highest QSO-per-hour rate. That argument misses the point entirely. The QSO-per-hour rate is not the problem. The problem is that while such an operation is in process, all normal day-to-day communications come to an abrupt halt. This hardly endears us to our fellow hams. While a few wrote to say that all split-frequency operations should be banned (transceiver owners, no doubt), the majority favored spreading the calling stations out over no more than 15 to 20 kHz. If this proves inadequate, the DX station can go by call areas or even by prefixes within call areas. There are many ways to ensure a successful DXpedition, but widespread calling is not one of them.

Johanna OY5J has been showing on 14240 kHz Mondays after 2330Z. This is the group led by WA2JUQ and a number of rare-type DX stations can usually be found checking in looking for the deserving ones.

5H3KS has been drawing massive CW pileups almost daily on 21022 kHz from 2330Z.

Seems like 7J1 is still high on most-needed lists in the W2 area. The JARL is reportedly aiming for another all-out effort after the monsoon season.

OE6EEG is said to be planning another 8Z4 effort for right about now.

Scotty K5CO and Dave N2KK plan to remove the entire Indian Ocean area from your needed list and are right on schedule. They plan to start on FR7 Reunion Island around the first of December and then sweep through the area, taking no captives. Dave is gearing up for some extensive 40 through 160 action, while Scotty handles the 10/15/20 demand.

Seven or eight S79 stations did manage to get their licenses renewed on June 1st, but the fee was a bit stiff—$82.00 each.

FH8OM and FH8YL ask that cards be sent via their managers only. Seems that someone in the local post office is an avid green-stamp and IRC collector.

Those new J7 prefixes replace the old VP2D prefixes. Al VP2DD now signs J7DD.

VQ9TC now signs KG6JIQ.

There is a new DX-DX SSB net on 7082 kHz at 0500Z. N5RQ takes stateside check-ins at 0630Z on 7165 kHz.

CQ Magazine has raised the price on all DX Certificate applications to $5.00.

Any ZA activity you might hear is probably Slim, but, of course, work them anyway. It will keep you in practice for that day when the real thing appears. The present situation is as follows: The license application by SM4CMN and SM3VE is being ignored, DL7FT (who was

LETTERS

BEFUDDLED

I must admit that I like your magazine; technically, it strikes a middle ground between the continuous brilliance of *Ham Radio* and the occasional gems in *QST*. Nevertheless, the political ramblings leave me a bit befuddled.

For instance, I notice regular references to the "debacle" of incentive licensing. So what's the hassle? If you want the greater privileges, you get off your ass, stop complaining, and study for the next higher license.

If any body should *not* be complaining, it's you, Wayne. The way I figure it, you do a pretty penny's worth of business in code tapes and study guides for aspiring applicants. Seems to me if incentive was dumped, you'd have a major "walletectomy" there.

But, ignoring that, I *still* don't see what's so bad. Incentive licensing is the same system that made America great: Those with higher rank get higher privileges. I'm convinced any one of us could get the Extra if he was motivated to study enough. At least, unlike business or military worlds, hard work guarantees results.

Seems to me incentive licensing is like the American socioeconomic system in a microcosm. I don't see how you could like one and not the other.

By the way, I don't hold the Extra class, so this isn't the voice of the "haves" telling the "have-nots" to be happy and shut up. It's just in recognition of a damn good system that apparently still needs defense.

I also doubt that this will ever get into your rag since I've tacitly called all of you anti-incentive types un-American.

At any rate, your mag is basically good, if all you read is the technical stuff. I *may* even renew.

Bob Lombardi WB4EHS
Ft. Lauderdale FL

Bob, you need to talk with someone who has been around amateur radio for a few years and then you would understand the irony of the term "incentive licensing." Sure, the system is working pretty well now, but do you honestly think that what you see now is all we ever had?

In 1963, the League proposed what they called "incentive licensing." The idea was to go back thirty years to the licensing system of the 1930s. They proposed taking most of the phone bands away from the General class, the way it was pre-WWII. I put up such a fuss that eventually the FCC only took half the phone bands away. The whole idea was to get amateurs to upgrade. I said they would do better if they gave rewards for upgrading; the ARRL said it would be better to take frequencies away and then give them back if you upgraded. The basic difference was one of punishment vs. rewards.

This brought on ten years of zero growth, little upgrading (I have published the facts and figures showing the extent of this disaster), and the death of all of the major manufacturers. Then the FCC put through my suggestion of giving the callsign of your choice to Extra class licensees...and clubs responded to my plan for getting them to offer Novice study courses, for which I published instruction manuals and provided code tapes. Amateur radio finally started to grow again and at last we had an increase in Extra class licensees.

The League saw what was happening and put out their own code course and did their best to cover over the incentive licensing fiasco. By the way, the FCC admitted that this was a complete debacle . . . that's why they changed the system to the present one . . . which is working reasonably well.—Wayne.

STRIKING DISTANCE

It was over a year ago that you very kindly sent me the *73* code system tapes, i.e., 5, 6, 13, and 20+ wpm, which were available at that time.

Now that I'm copying the 20+ at about 95% and working out at that speed, I thought you might like a breakdown of progress since starting and until now.

First, let me say that I think your system is excellent and without it would never have passed my CW test nor obtained my ZS (unrestricted) license here In South Africa.

Being a Master Mariner and a Nautical Examiner of Masters and Navigating Officers and also an ex-lecturer/training officer of cadets preparing for the Mercantile Marine, I feel I'm qualified to give an opinion on your training method, which I feel is without equal.

Second, although I'm 54 years of age, I have always, since going to sea at 14, known the Morse code, so I didn't have to learn the characters from start. But, in the Mercantile Marine, candidates for the various Certificates of Competency are required to "satisfy the examiner of their ability to send and receive signals in Morse code by *flash lamp* up to 6 wpm."

I think you will agree that there is a world of difference between copying a flashing light at 6 wpm and sound. So I virtually had to start from scratch insofar as sound was concerned.

I started on the 5 wpm tape in May, 1978. In July (just over 2 months later), I passed the CW test (12 wpm) and received my ZS license. Since then, I have had nearly 500 QSOs on CW and I can thank you for giving me that pleasure.

From the 13 wpm tape, I moved to the 20+ wpm tape in August, and by December, some 5 months later, I was copying about 80%. As I have said already, I'm copying about 95% now.

Now I'm practicing on local weather reports in order to learn to copy at 25-30 wpm. It has been your excellent system which has placed me within striking distance of my goal.

Norman Caseley ZS5NC
Pinetown, South Africa

CUSHCRAFT

It seems that we are always hearing stories of problems with service, quality, and delivery from the many manufacturers and dealers of amateur radio equipment and supplies. I feel equal recognition should go to the manufacturer or distributor who gives service above and beyond the call of duty.

A couple of weeks ago, I purchased from a local dealer a Cushcraft ATB-34 triband beam. At the same time, I contracted a man with a crane to help me put it on my tower. Upon assembling the antenna 3 days before it was to be installed, I unfortunately encountered a defective part. I thought my deposit to the installer was lost because I contracted for a particular time and day and I knew for sure that the part would never make it from the wilds of New Hampshire to New Jersey in the 2 days I had left. After a phone call to Cushcraft and a conversation with a gentleman named Hugh, I found out my worries were unfounded. At their expense, they navigated through the woods and mountains of New Hampshire to the nearest post office immediately after my phone call. They had the part shipped Express Mail with a promise from the US government that the part would be at my door within 24 hours. Sure enough (for a change), the government was right. I had the part the next morning and the antenna went up the following day as scheduled.

This personal service was, in my opinion, far beyond what can be generally expected from most of the companies with whom I have dealt in the past. Granted, if something you purchase is under warranty, it will be repaired or a defective part replaced, but usually with a long delay even under emergency conditions as was my case.

This experience with Cushcraft service shows the concern the company has for the consumer *after* the sale is made. Unfortunately, this cannot be said for many other companies I have dealt with.

Ed Feins WA2ZDN
Linden NJ

WOODPECKING

I heard something on twenty last night that bothered the heck out of me. Please recall the correspondence concerning the "Russian woodpecker" and its cure from about two months ago. If you have not heard already, this cure (CW tones in pace with the radar pulses) no longer works.

Apparently the defense taken by amateurs was too effective for the Russians, for they have modified their system. The tones are no longer the broadband clicks of yore, but seem now to be a type of broadband FM. It sounds like the only way to cope with this would be to sync slow-scan signals on top of the radar, or use recordings out of sync to throw off their video display. Either cure is worse than the disease, with slow-scan and radar recordings chasing the intruder up and down the band!

Wayne, please tell your readers that *any time* they hear the "woodpecker," they should immediately call the nearest FCC monitoring station. It's been said before, but if they get bothered with enough calls, we may get something done.

I haven't listened to the bands in the last week or so, so

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

As much as I hate to do this, I am starting this month's column with a word of caution. In my February, 1979, "RTTY Loop," I relayed a blurb sent to me by a firm called "Teleprinter Art, Ltd." in Urbana, Illinois. The company presented itself as a source for all kinds of RTTY artwork, at reasonable prices. Its catalog is decorated with samples and stocked with many delightful bargains. If only it were true! Over the past few months, I have received letters from several individuals who have ordered material from Teleprinter Art, Ltd., and never received anything but their cashed checks. Communication with the management of the company has been fruitless, and as of this writing almost one month has elapsed since I sent a letter of inquiry to them. No reply has yet been received. While I acknowledge that to date there is no conclusive evidence of wrongdoing by Teleprinter Art, Ltd., I would urge anyone anticipating doing business with that firm to approach the transaction with reasonable caution. If anyone has further experiences regarding this company, either positive or negative, I would be interested to hear from you. I shall try to forward any such information to you all as received, and to keep you posted on the situation in general.

Moving from the questionably secret to the openly clandestine, many of you have been writing in asking about press and weather frequencies. Fig. 1 is an attempt to answer some of those questions. Now, before you get all bent out of shape and totally snowed by the chart, let me do some explaining. As suggested a few months ago, most of the commercial RTTY stations do not transmit "ham standard" 60-wpm, 850-Hz or 170-Hz shift, low-space RTTY. They *do* send anything they darn well want to, including strange shifts, shift direction, or speed. Thus the table.

Whether or not you can copy the transmitted shift is more a function of the converter than anything else. By straddle-tuning, almost any shift should be copyable. The ST-6, for example, can copy 425-Hz shift with the autostart turned off. You will just have to try yours and find out.

The speed may present more of a problem if you are using a machine which is not geared for the frequently-found 67 wpm speed. Most Model 15s and 19s will do fairly well if the range selector is set to the high end. Again, experimentation may be the best bet.

As more of these frequencies are received, I will try to compile them and include a list, periodically, in the column. Let me know what you hear, and I'll pass it along.

A letter received from Richard Black W2DBU asks about the use of the ASR-33 on a Baudot/Murray circuit following code conversion. Richard writes, "... you mentioned that the ASR-33 is just too slow to receive 60-wpm RTTY. I do not understand this as I believe that the old Baudot printers could copy this speed. Is not 60 wpm about 45 baud?"

The answer to the question is, "Yes and no!" While 60 wpm is 45.45 baud and the ASR-33 copies at 110 baud (or 100 wpm), that is not the problem. The statement was made with respect to a code conversion program which used a software UART for receiving the RTTY. Thus, decoding could not begin until the last data pulse had been received. Following decoding, the data must be sent to the printer before the next start pulse is expected. In a worst-case situation, i.e., receiving at "machine speed," this leaves the length of the stop pulse, about 31 ms, to send the character to the printer. In order to send one ASCII character in 31 ms, you need to send at a rate of at least 300 baud. That is where the problem lies. If you are content to pause 100 ms or so after each character is sent, the ASR-33 will be able to follow. But you can't do that practically, so you really can't use a 110-baud printer.

Remember, however, that the constraint on the system is that the processor must be available for the full time that a character is being received. What if, you might suppose, you presented the entire character at one time; could you then use a 110-baud output? Of course, you can! The way to implement this is to use a hardware UART such as a 1013 to receive the RTTY, allow the processor a few microseconds or so to do a code conversion, and dump the ASCII into another UART or ACIA. This would work just fine, but it was not the scheme of the program. Hope this clears things up for you, Richard.

NEAT TRICKS DEPARTMENT

From time to time, I will try to pass along some neat tricks which can save you time and money while playing with your RTTY. I am sure that most of you are aware that replacement ribbons for your Teletype™ machines are available at any stationery and many variety stores. No, they may not be labeled as such, but any ribbon which fits an Underwood standard typewriter will fit your Teletype machine just fine. There comes a time, however, when you need a dark image and no new ribbon is available. What then? Well, it turns out that most light ribbons are not out of ink, they are just dried out. A little solvent will frequently bring new life to an old ribbon, with almost no effort. What I do is spray some contact cleaner (I use one called LPS-1) along the length of the ribbon while the machine is spacing. Don't spray too much or you will have an inky mess of a machine. You want to just dampen the ribbon. Wait overnight for the excess to evaporate, and you have a rejuvenated ribbon. Like I said, *neat trick*!

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 6

mance at the last WARC in 1959 is any criterion, where League officials were flown over at League expense, even with their salaries being paid by the League, and for no more important function than to attend some lavish parties, then they might indeed run through the three-quarters of a million.

Will the League again have a lavish suite of rooms in one of the most expensive hotels in Geneva, all paid for by some 80,000 generous League members? The concept of Yankee thrift seems not to extend down to Connecticut. If you are sucker enough to eagerly send in your hard-earned money for these turkeys to enjoy themselves at your expense, so be it.

While on the one hand I keep hearing the moans of poverty from Newington, on the other I look at their recent balance sheet and find that their net worth increased last year by almost 10%. Most firms would count that as a profit, but the League, being "non-profit," shuffles the bookkeeping around and puts the funds into stocks and bonds (they have over $1.5 million sitting in securities).

The election of directors is coming up this fall and half of the directors are up for re-election. If you blindly return these chaps to office, then *you* must share in the responsibility for what is happening. With the exception of Don Miller, you have nothing to lose by turning the lot of them out. Darned few are active hams anyway... they are politicians and they're using your money for gratifying their egos. With some new directors, you might have a chance of getting the entrenched clique kicked out of HQ and getting someone with business experience into the job.

I think every amateur really wants to be able to be proud of the ARRL and see it regain its leadership position. But we can't respect it when we see the double-talk and cover-ups... and when we see everyone we've known at HQ for years getting the hell out... except for Baldwin and Dannals.

It is the responsibility of the directors to see that they have an HQ staff which will run the organization in the black. It is the responsibility of the members to see that they vote in directors who will run the organization and not be buffaloed by a couple of people at HQ. In the meanwhile, sending more money to the League will

Microcomputer Interfacing

Jonathan A. Titus
Christopher A. Titus
David G. Larsen
Peter R. Rony

The purpose of this month's column is to introduce the reader to some of the characteristics of the Intel 8253 programmable interval timer, an extremely versatile I/O chip that can be used in a wide variety of potential applications, such as a real-time clock, event counting, and period counting, in addition to the replacement of software-implemented timing loops.

The 8253 is a 24-pin integrated circuit that requires a single 5-volt supply and contains three independent 16-bit *interval timers*, each of which can be operated in six different modes. An *interval timer* has been defined by Graf's *Modern Dictionary of Electronics* as a device for measuring the time interval between two actions or a timer that switches electrical circuits on or off for the duration of the preset time interval. Fig. 1 serves the dual purpose of giving the pin diagram of the 8253 chip and showing how the chip can be interfaced with an 8080A/8085-based microcomputer system using memory-mapped I/O.

The 8253 chip contains four internal registers (three interval timers and a control register) that are decoded as memory locations 200 000 through 200 003 with the aid of the address bus signals A0, A1, and A15 (see Fig. 1 and Table 1). Observe in Table 1 that the $\overline{RD}$ and $\overline{WR}$ control inputs determine whether you are loading or reading a specific register. It is not possible to read the contents of the control register.

Table 2 summarizes the coding for the 8-bit control register within the 8253 chip. Observe that bits D7 and D6 determine the selection of the interval timer, bits D5 and D4 determine the nature of the read/write operation associated with the chosen timer, bits D3, D2, and D1 determine the mode of operation of the chosen timer, and bit D0 determines whether the timer counts down in binary or binary-coded decimal (BCD).

Fig. 2 provides a block diagram for a typical counter in the 8253 chip. The microcomputer loads the 16-bit down counter as two successive bytes, a HI byte and a LO byte, via the bidirectional data bus, D0 through D7. If the gate line GATE is active, negative edge transitions at the CLK input decrement the counter. When the counter reaches zero, OUT becomes active, its actual behavior depending upon the mode programmed into the control register for the counter (see Table 2). The 8253 chip contains three independent 16-bit counters, and each can be programmed independently in any one of the six modes of operation. The counter inputs and outputs, CLK, GATE, and OUT, for the chosen counter are independent of the CLK, GATE, and OUT input/output of the remaining two counters on the chip.

In addition to the address bus, data bus, and control bus connections shown in Fig. 1, the CLK0 and GATE0 inputs to counter #0 are respectively connected to the $\phi 2$ (TTL) microcomputer clock output (typically 2 MHz) and to bit 0 of accumulator output port 000. Any TTL level clock with a frequency of less than 2 MHz can be used as input to CLK0, and any suitably debounced switch or source of strobe pulses can be used to control the timer at GATE0. The output of the counter OUT0 can be connected to an oscilloscope to permit observation of each of the six timer modes of operation.

$\overline{CS}$	$\overline{RD}$	$\overline{WR}$	A1	A0		Memory address in demonstration program and interface circuit
0	1	0	0	0	Load counter #0	200 000
0	1	0	0	1	Load counter #1	200 001
0	1	0	1	0	Load counter #2	200 002
0	1	0	1	1	Load control register	200 003
0	0	1	0	0	Read counter #0	200 000
0	0	1	0	1	Read counter #1	200 001
0	0	1	1	0	Read counter #2	200 002
0	0	1	1	1	No operation (three state)	–
1	X[a]	X	X	X	Disable chip (three state)	–
0	1	1	X	X	No operation (three state)	–

X[a] = don't care (logic 0 *or* logic 1).

Table 1. Addressing the 8253 programmable interval timer.

Bits			Control function
	D7	D6	
	0	0	Control word is for counter #0
	0	1	Control word is for counter #1
	1	0	Control word is for counter #2
	1	1	–
	D5	D4	
	0	0	Latch both bytes of chosen counter for read operation
	0	1	Load or read only most significant byte of chosen counter
	1	0	Load or read only least significant byte of chosen counter
	1	1	Load or read LS byte first, then MS byte of chosen counter
D3	D2	D1	
0	0	0	Mode 0: Output = 1 on zero counter
0	0	1	Mode 1: Retriggerable variable-width one shot
X[a]	1	0	Mode 2: Programmable rate generator
X	1	1	Mode 3: Programmable square wave generator
1	0	0	Mode 4: Delayed strobe (software triggered strobe)
1	0	1	Mode 5: Triggered strobe (hardware triggered strobe)
		D0	
		0	Count down in binary
		1	Count down in binary-coded decimal (BCD)

X[a] = don't care (logic 0 *or* logic 1).

Table 2. Coding for the 8-bit control register in the 8253 chip.

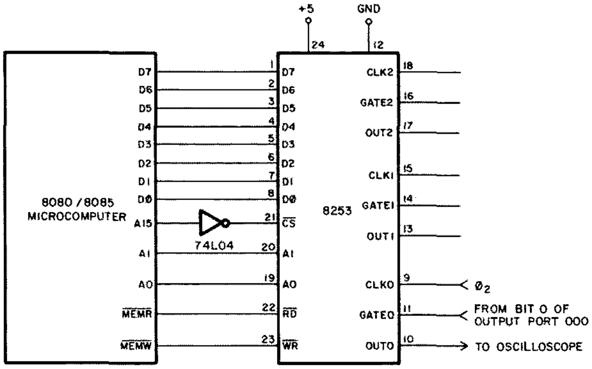

Fig. 1. Interface circuit between a 8253 programmable interval timer and an 8080/8085 microcomputer. The 8253 chip uses four locations of memory in this memory-mapped interface circuit.

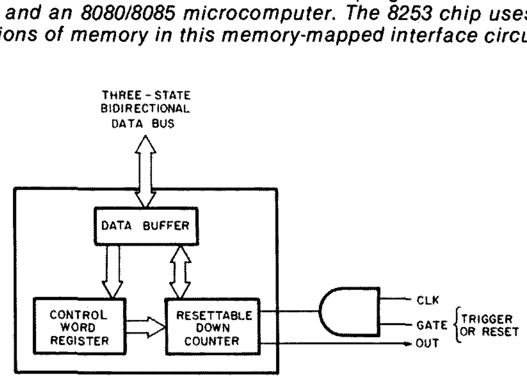

Fig. 2. Functional diagram of each of the three 16-bit interval timers in the 8253 chip. The gate input acts alternatively as a gate, trigger, or reset input, depending upon the mode chosen.

Ham Help

I need some help. I have recently inherited a Hammarlund HQ-120X receiver and I am badly in need of a diagram. If anyone out there can help, I would gladly pay for copying costs. Thank you.

Louis A. Johnson
32 Crosscreek Drive, Apt. I 3
Charlestown SC 29412

I am in need of maintenance manuals for the following:

1. Standard signal generator, model 82, manufactured by the Measurements Corporation of Boonton NJ.

2. Frequency meter, FR-114 A/U, made by Sentinel Electronics, Inc.

3. Signal generator, TS-323 U/R.

I will be happy to purchase these manuals or copies of the pertinent maintenance data, schematics, etc., and pay cost of mailing.

Robert L. Marcon W5CBW
Rt. 7, Box 96A
Lucedale MS 39452

Awards

Bill Gosney WB7BFK
2665 North 1250 East
Whidbey Island
Oak Harbor WA 98277

Note: The address shown for Bill Gosney in the August issue of 73 was incorrect. The correct address is that shown above.

As editor of *73*'s newest column, I'm quite impressed with the warm reception received from so many of our readers situated throughout the world. Obviously, my recent announcement of an exclusive *73* Awards Program has turned quite a few heads and stimulated the interest of a great many. I thank you all for your written support arriving from all continents on the globe.

Without further to-do, let's turn to part II of our two-part series and learn for the first time about the four stateside award programs being sponsored by *73*. Keep in mind that these awards were not meant to be an overnight venture nor were they designed to duplicate any in existence today. Each offers its own degree of difficulty and creates a sense of accomplishment amongst those who are happy recipients.

WORK ALL USA AWARD

Sponsored by the editors of *73 Magazine*, this award is available to licensed amateurs throughout the world. To be valid, all contacts must be made January 1, 1979, or after. There are no band or mode restrictions; however, single-band accomplishments will be recognized.

To qualify, applicants must work each of the 50 US states within the same calendar year (January 1 through December 31). Annual endorsements will be afforded those applicants who can substantiate their claim.

To apply for the Work All USA Award, make a self-prepared list of claimed contacts in alphabetical order by US state, beginning with the state of Alabama. Indicate the state, the callsign of the station worked, the date and time in GMT, and the band and the mode of operation.

Do not sent QSL cards! Have your list of contacts verified by two amateurs, a local secretary, or a notary public. Forward your application along with the award fee of $3.00 or 8 IRCs to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

As you quickly surmised, the Work All USA Award with its 12-month limitation, more or less in a manner of speaking, separates the men from the boys when it comes to working all states.

Regardless of how difficult it may first appear, applicants who choose to work a few of the contesting events held each month or check into a few of the WAS nets will find the USA Award a relatively easy accomplishment.

Now, on the other hand, should you care to undertake an even greater challenge, take a hard look at this next award. This one was designed to appear fairly simple at first glance, but will drive you right up the wall with frustration as it is pursued. Known as the District Endurance Award, you'll need to find yourself an accurate timepiece, as you'll have exactly sixty minutes to work all US call districts. Simple, huh? Read on; there is a catch:

DISTRICT ENDURANCE AWARD

This award, sponsored by the editors of *73 Magazine*, is offered to licensed amateurs throughout the world. To be valid, all contacts must be made January 1, 1979, or after. There will be no band or mode restrictions. Contacts while a contest station or while working a contest station will not be allowed. Likewise, contacts made on any type of net operations will be invalid.

To qualify for this award, applicants must work all ten US call districts in one hour or less. The time will commence the moment the first contact is made and will end with the time logged for the last district required.

To apply, applicants must prepare a signed declaration that all contacts were independent of contest or net operations. Applications should include a self-prepared list of claimed contacts in order of their prefix. Include the date and time worked in GMT, the band and mode of operation, and the state.

Do not send QSL cards! Have your list of contacts verified by at least two amateurs, a local radio club secretary, or a notary public. Forward your application along with the award fee of $3.00 or 8 IRCs to the attention of: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

What would an awards program be like without some sort of QRP incentive? With this in mind, the editors of *73* feature a special ten-meter achievement award. Being an avid user of converted Citizens Band equipment, I found personal interest in this award and hope our readers will share the challenge.

TEN-METER 10-40 AWARD

Available to licensed amateurs worldwide, this award sponsored by the editors of *73 Magazine* offers a challenge second to none. To be valid, all contacts must be made on the 10-meter band using only "channelized" converted Citizens Band equipment or similar type "commercial units." Power is limited to 15 Watts pep output. External amplifiers may not be used.

To be eligible, all contacts must be made October 1, 1978, or after on either AM, SSB, CW, or FM. Mixed mode contacts are not valid.

To qualify for this Ten-Meter Award, applicant must work and confirm at least forty (40) of the 50 US states. An endorsement for all fifty states will be issued to those who verify their claim.

To apply, make a list of contacts in alphabetical order by US state beginning with Alabama. Include the full callsign, date and time worked in GMT, band and mode of operation, and a brief description of the equipment used for each contact claimed.

Do not send QSL cards! Have your list verified by two amateurs, a local radio club secretary, or a notary public. Send your application along with your award fee of $3.00 and 8 IRCs to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

As noted in the Ten-Meter Award rules, recognition is given for single-mode contacts only. To the best of my knowledge, this award is the only one in existence that offers FM endorsement. Should you or a friend be involved in the latest craze of 10-meter FM operation, be sure to pass the word along that we have an award designed especially for you. While you are at it, why not lend your September as well as this October issue of *73* to fellow amateurs who are not aware of our new awards program? All eight domestic and DX achievements are outlined.

Though the title may be deceiving, this next award is probably the ultimate in our domestic program. Consider it the toughest to attain. A look at the requirements clearly identifies the degree of difficulty in obtaining this award. Luckily we were sympathetic enough to eliminate any time limitations.

CENTURY CITIES AWARD

This award, sponsored by the editors of *73 Magazine*, is available to licensed amateurs throughout the world. Designed as a dual Work-All-USA effort, the applicant who qualifies for this accomplishment will realize he has achieved what is probably the greatest feat in domestic award programs available today.

As with all the *73*-sponsored awards, with the exception of the 10-meter incentives, all contacts must be made January 1, 1979, or after to be valid.

To qualify, the applicant must work and confirm a minimum of two cities or towns in each of the fifty (50) US states for a total of 100 US cities.

To apply, prepare a list of claimed contacts, listing each one in alphabetical order by state. As shown below, include the full callsign of the station worked, the date, the band, and the city. Beginning with Alabama, your list will look something like the following example:

Alabama—W4ZZZ, March 31, 1979, 14 MHz, Decatur; N4XXY, February 1, 1979, 21 MHz, Mobile. Alaska—KL7AB, January 22, 1979, 7 MHz, Anchorage; WL7WW, May 19, 1979, 28 MHz, Fairbanks.

Do not send QSL cards with your application! Have your list of contacts verified by two amateurs, a local radio club secretary, or a notary public. Enclose your verified list along with the award fee of $3.00 or 8 IRCs and send to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island, Washington 98277 USA.

ARROWHEAD RADIO AMATEUR FIFTY-YEAR CERTIFICATE

A free certificate is being offered by the Arrowhead Radio Amateur Club of Duluth, Minnesota/Superior, Wisconsin, to celebrate fifty years of organized amateur radio in the Twin Ports area.

For this award, any amateur within fifty air miles of Duluth/Superior is considered an Arrowhead amateur. To receive this award, US and Canadian amateurs must work five Arrowhead amateurs; all foreign amateurs must work two Arrowhead amateurs during the month of October, 1979.

Contacts made during the Arrowhead Radio Amateurs Fiftieth Anniversary QSO Party on October 20 and 21, 1979, may be used for this certificate.

Logs must show band, mode, date, time in UTC, and stations worked to receive this award. Send logs, with SASE or IRC, to Arrowhead Radio Certificate,

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

CALIFORNIA QSO PARTY
Starts: 1800 GMT October 6
Ends: 2359 GMT October 7

Single-operator stations are limited to 24 hours operating time with on and off periods clearly marked in the log. Multi-operator stations may operate the full 30 hours. Stations may be worked once per band per mode, simplex only. CA stations that change counties may be considered new stations.

EXCHANGE:

CA stations send QSO number and county. All others send QSO number and state, province, or ARRL country.

FREQUENCIES:

CW—1805, 3560, 7060, 14060, 21060, 28060.

SSB—1815, 3895, 7230, 14280.

Novice CW—3725, 7125, 21125, 28125.

SCORING:

Each complete contact is worth 2 points; CA stations count the 50 states plus VO/VE 1-7 and VY1 for a maximum of 58 multipliers; non-CA stations will use the number of different CA counties worked, a maximum of 58. Final score equals QSO points times the multiplier.

ENTRIES:

Summary sheet and logs must be postmarked not later than November 1 and sent to: NCCC, c/o Alan Brubaker K6XO, 34456 Colville Place, Fremont CA 94536. Please include a business-size SASE with your entry. Awards for individuals and clubs will be awarded.

QRP ANNUAL OCTOBER QSO PARTY
Starts: 2000 GMT Saturday, October 6
Ends: 0200 GMT Sunday, October 7

Sponsored by the QRP Amateur Radio Club International, Inc., the contest is open to all amateurs and all are eligible for the awards. Stations can be worked once per band for QSO and multiplier credits. General call is "CQ QRP."

EXCHANGE:

Members send RS(T), state/province/country, QRP number. Non-members send RS(T), state/province/country, power input in Watts.

SCORING:

Each member QSO counts 3 points. Non-members count 2 points per QSO. Stations other than W/VE count as 4 points. Multipliers are as follows: more than 100 Watts input = x1, 25 to 100 Watts = x1.5, 5 to 25 Watts input = x2, 1 to 5 Watts input = x3, and less than 1 Watt input = x5. Final score is QSO points times total number of states/provinces/countries per band times the power multiplier.

FREQUENCIES:

CW—1810, 3560, 7060, 14060, 21060, 28060, 50360.

SSB—1810, 3985, 7285, 14285, 28885, 50385.

Novice—3710, 7110, 21110, 28110.

All frequencies plus or minus 5 kHz to clear QRM.

AWARDS:

Certificates to the highest-scoring station in each state, province, or country. Other places will be given depending on activity. One certificate for the station showing three "skip" contacts using lowest power.

ENTRIES:

Send full log data, including full name, address, and bands used, plus equipment, antennas, and power used. Entrants desiring result sheet and scores please enclose a business-size SASE. Logs must be received by October 31 to qualify. Send all logs and data to: QRP ARC Contest Chairman, E. V. Sandy Blaize W5TVW, 417 Ridgewood Drive, Metairie LA 70001.

9-LAND QSO PARTY
Starts: 1800 GMT Saturday, October 13
Ends: 2359 GMT Sunday, October 14

A maximum of 24 of the 30-hour period may be worked.

EXCHANGE:

9-land stations send RST, county, and state. All others send RST, state, province, or ARRL country. The same station may be worked once per band and mode. If any station change counties, it may be worked again.

SUGGESTED FREQUENCIES:

CW—1805, 3560, 7060, 14060, 21060, 28060, +VHF.

SSB—1815, 3895, 7230, 14280, 21355, 28600, +VHF.

Novice—3725, 7125, 21125, 28125.

AWARDS:

Certificate to top score in each state, province, and ARRL country, 2nd and 3rd if justified. Also top mobile, portable, multi-single, multi-multi, club, and Novice.

SCORING:

Each QSO is worth 2 points. Scores shall be computed as follows: 9-land—(#QSOs) (states + provinces + ARRL countries + 9-land counties) (2 points/QSO) = total; others—(#QSOs) (9-land counties) (2 points/QSO) = total.

REPORTING:

Submit summary sheet and log. Each new multiplier shall be clearly indicated. Send logs and a large SASE to Ill Wind Contesters, c/o John W. Sikora WB9IWN, 8155 Woodlawn Street, Munster IN 46321, for results.

ARROWHEAD FIFTIETH ANNIVERSARY QSO PARTY
Operating periods:
1500 GMT October 20 to 0300 GMT October 21
1500 GMT to 2359 GMT October 21

This QSO party is sponsored by the Arrowhead Radio Amateurs Club and is to help celebrate fifty years of organized amateur radio in the Duluth MN-Superior WI area. The club was first affiliated with the ARRL in 1929. The contest is open to all radio amateurs. All amateurs within 50 air miles of Duluth/Superior are considered Arrowhead amateurs in this contest. Arrowhead amateurs may work anyone; amateurs outside the area may work only Arrowhead amateurs. The same station

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

OSCAR 7 Orbital Information

FCC

Some 73 readers have inquired about the legality of building and using the MDS receiving system featured in the August, 1979, issue ("You Can Watch Those Secret TV Channels"). In response to these inquiries, an FCC Public Notice (dated January 24, 1979) on MDS is reproduced here.

The key issue seems to be whether the reception of MDS transmissions by an amateur experimenter constitutes an illegal "benefit" under Section 605 of the Communications Act. Before you construct your own MDS receiving system, we urge you to read the material below.

UNAUTHORIZED INTERCEPTION AND USE OF MULTIPOINT DISTRIBUTION SERVICE (MDS) TRANSMISSIONS

In response to a few informal inquiries and complaints, this Notice is a reminder that the unauthorized reception and beneficial use of addressed communications in the Multipoint Distribution Service (MDS) is a violation of Section 605 of the Communications Act of 1934 (47 U.S.C. §605).

MDS is a common carrier service which utilizes an omnidirectional radio transmission to distribute addressed broadband communications (usually forms of television information) for simultaneous reception at multiple fixed receive points by the members of commercial, or other institutional, subscribers in accordance with their specific transmission, reception, and informational requirements.

MDS stations are not television broadcasting stations. They operate on microwave radio frequencies (2150-2162 MHz) which are allocated for common carrier service between fixed points, and which, because of their high frequency, are not receivable by conventional television or other receivers. Additional equipment is required to down-convert or to demodulate the microwave signal before it can be utilized by those television receivers, facsimile terminals, or computer data display terminals authorized to receive the communication by its sender.

Nor are MDS stations disseminating radio communications intended to be received by the general public. MDS station transmissions generally consist of various forms of private television, high-speed computer data, facsimile, control information, or other forms of addressed broadband communications. This programming is provided to the station by its institutional subscriber and is intended to be received only by members of the subscriber organization located at the multiple receive points. The MDS station transmits this programming pursuant to a federally-regulated tariff and is responsible for both its transmission and reception under Section 21.903 of the Commission's Rules and Regulations (47 C.F.R. §21.903). Although this rule permits the station's institutional subscriber the option of owning the microwave receiving equipment, such equipment must be installed, maintained, and operated pursuant to the carrier's instruction and control.

Section 605 of the Communications Act makes it unlawful:

—for a person not authorized by the sender to intercept radio communications and divulge or publish the existence, contents, substance, purport, effect, or meaning thereof to any persons; or,

—for a person not entitled thereto to receive radio communications and *use such communication or any part thereof for his own benefit* or for the benefit of another who is not entitled thereto (emphasis added).

Because material transmitted over stations is not intended to be "broadcast" material within the meaning of Section 605, authority for its reception and use must be given by the sender. Therefore, persons will be in violation of the law if they divulge, publish, or use for their own benefit any MDS communications which they were not authorized to receive.

Violations of Section 605 can result in either criminal prosecution or civil lawsuit, or both. *See KMLH Broadcasting Corp. v. Twentieth Century Cigarette Vending Corp.*, 264 F. Supp. 35 (C.D. Calif. 1967).

Ham Help

I have a Heathkit® SB-110A 6m SSB/CW transceiver. I was thinking about getting a new rig that was more up to date, but after I saw the price tags on them, I decided to keep the 110A. Can anyone recommend a noise blanker for this rig?

I'd like also to find out about all mods that can be done to the SB-110A to modernize it. I would appreciate any information that anyone can give me. Thanks.

New Products

ICOM'S IC-701 ALLBAND ALL-SOLID-STATE TRANSCEIVER

When an Icom IC-701 transceiver arrived at the *73* shack, I was pleasantly surprised by the size of the three boxes that the rig, its companion power supply, and several other accessories were packed in. Times had certainly changed from when I stumbled through the door with a brand new tube-type rig just a few years ago. The 701's size (111 mm x 221 mm x 311 mm) and 7.3-kg weight make it an ideal competitor in the growing mobile radio market.

There is no tune-up to worry about, since the radio is broadbanded. You just set the band and frequency and start talking. It's almost as easy as operating a 2-meter rig. The 701 has full coverage of the HF spectrum in the USB, LSB, CW, and RTTY modes. Receive capability for the 15-MHz WWV signal is also included.

After the rig was unpacked, there was concern as to how such a small box could possibly do so much. The controls seemed to be crowded and it looked easy to make a mistake. A month of operating has proven this to be an ill-founded fear. The front panel is well laid out—Icom certainly engineered it well.

The solid-state finals don't need any coaxing to reach their rated 200-Watt input level. A thermostatically controlled fan is included, but in normal SSB use it has never had to kick in. This rig runs cool. It is important to use a well matched antenna with your 701, a small price to pay in an age when many ham shacks have antenna tuners already. If the transmitter does overheat, the flashing frequency display lets you know that it's time to pull the switch and find out what's wrong.

Versatile Vfos

Anyone who operates *73*'s IC-701 mentions the synthesized tuning as an outstanding feature. The computer-compatible tuning system allows 110-Hz increments in frequency selection. Even the most discriminating amateur should be pleased with being no more then 50 Hz from the desired frequency. The musical effect that occurs when a heterodyne is tuned in always brings a smile to the face of a first-time user.

The tuning knob has a 5-kHz per revolution change, but a "fast tune" position allows the band to be covered in seconds. The only analog readout available is from the 100-Hz and 1-kHz dial markings. The idea of being totally dependent on a digital display doesn't seem so bad when you remember that dial backlash and the like are things of the past with the IC-701. No external vfo is needed, since the rig contains two independent ones. It is handy to set vfo "A" on a particular receive channel and use vfo "B" for transmitting when working DX. Total flexibility is the best way to describe it.

This rig stands apart from the rest when an Icom IC-RM2 is hooked to the accessory socket. It is a whole new world of operating when you can change bands and enter frequencies from a keypad. Push a button and you are on a completely different band and predetermined frequency; push another button and the 701 scans to the band edge, all in less time then it takes to say your callsign. The RM2 provides a second digital readout that is smaller than the 701's display, but it is still very useful. Four frequencies may be stored in memory and three different scanning rates are available. Any number of schemes involving remote operation, crossband repeaters, etc., are possible, thanks to the computer-compatible tuning system.

Icom's IC-701 transceiver.

Helpful Extras

No matter how versatile the Icom IC-701 synthesizer is, the rest of the rig must also be considered. Despite the lack of any pre-select control, the receiver seems to offer a sensitivity that is comparable to tuned rigs. SSB reception lacks any tinny or echoing quality, and the external speaker does a more than adequate job. The passband and RIT features are very smooth and go a long way in eliminating troublesome QRM. The instruction manual honestly states that the noise blanker works best with pulse-type noise, but may not be effective in all cases. Mobile operators may not be interested in features like a 10-dB attenuator and selectable agc, but Icom includes them for amateurs who take their operating seriously.

Speech processors have become more than just an option with most new transceivers, and the 701 is no exception. Icom advertisements suggest that the rf processor may be left on all the time without worrying about the final transistors. However, we found that the added punch given by the processor means slightly less fidelity for the operator on the other end. Processing is definitely used when I am in a pileup or similarly tough situation. The proper adjustment of the speech processor and microphone gain can be a bit confusing at first, especially when you switch to CW and the process control knob sets the output level. Hams who split their time between SSB and CW will be pleased with the 701's separate VOX delay values for each mode. No compromise here—there is even a separate volume control for the sidetone.

The four VOX adjustments, plus seven other controls, are found under the access cover which is conveniently located on top of the radio. Icom has included an swr metering circuit. Unfortunately, it is easy to leave the "set" switch on, canceling the power-out (PO) metering. The swr meter is nice for making occasional antenna checks, but it can't compete with the external variety. Another frill is the dimmer switch. This allows the frequency display and meter illumination to automatically change when the room lighting shifts.

A Few Bugs

The IC-701's most noticeable deficiency was revealed when it came time to interface the rig to the real world. Use with many linear amplifiers will require the addition of a small 12-volt relay for switching and a 10k pot to control the ALC level. A more frustrating problem occurred when I tried to use an electronic keyer. The instruction manual dictates that the terminal voltage of any external keying device must be less then .4 volts dc. Since many keyers use electronic switching, they will not work here. When I contacted an Icom representative about this problem, he suggested that the keyer output circuit be modified. It was also mentioned that Icom does not consider this to be a fault of the 701, and no changes are planned.

To save space, a miniature phone jack is used for the key rather then the universally accepted ¼-inch type. If you want to use the IC-RM2 remote controller in addition to other accessories, it will be necessary for you to modify the 24-pin accessory plug or obtain the IC-EX1 extension terminal. The EX1 overcomes the switching relay problem and offers a ¼-inch-jack-to-miniature-phone-plug combination for CW keying. Although the interfacing problems are not insurmountable, they can mean an unneeded delay for the amateur who expects easy hookup.

Since the IC-701 relies heavily on digitally-based circuitry, rf shielding is very important. Correspondence with other hams—and on-air testing—have shown that feedback problems may occur, especially when the IC-RM2 remote controller and high-power amplifier are used. Good grounding practices and careful attention to the audio lines help to cure these bugs. The instruction manual gives adequate information on problems that may result from misadjustment of the normal user controls, but little information is available about other difficulties that may crop up.

Icom has incorporated more then 470 solid-state devices in the 701. The theory documentation provides a general outline of the design, but with a few exceptions, it does not give a detailed description of individual circuits. Because of the complexity and small size of the IC-701, it is doubtful that most hams would want to service it. Some instructions for internal adjustments are given. These often require a frequency counter, rf voltmeter, signal generator, or oscilloscope. A highly competent dealer or

Icom distributor is the best source of help for the less adventuresome owner.

Being limited to admiring the rig's outward appearance is not an unpleasant pastime. The IC-701 is a sharp looking, highly functional unit. Except for peeling lamination on the faceplate of the RM2, our 701, with accessories, has performed well during daily use for the past month. Although Icom's compact "black box" seems dwarfed by the nearby antenna tuner, it is a real performer. *Icom, 3331 Towerwood Drive, Suite 304, Dallas TX 75234; (214)-620-2780.*

30-MEGAHERTZ, DUAL-TRACE, PORTABLE MINISCOPE

Non-Linear Systems has increased the number of their Miniscope oscilloscopes to three with the introduction of their Model MS-230 30-megahertz, battery-operated, dual-trace miniscope. Its size is 2.9 inches high by 6.4 inches wide by 8.5 inches deep. The weight is 3.5 pounds, including batteries.

The MS-230 features alternate, chopped, and separate sweep modes. Internal and external trigger modes are included. There are 12 vertical gain settings for each channel's range, from 0.01 to 50 volts per division. Timebase settings range from 0.05 microseconds to 0.2 seconds per division. Verniers are provided for timebase and vertical amplifier adjustment.

The MS-230 Miniscope includes a horizontal input channel and an internal calibrator. The graticule consists of .25-inch divisions arranged 5 across and 4 high.

The MS-230 comes complete and ready to use. Included are input cables and a battery charger permitting battery or line operation. Accessories include a 10:1, 10-megohm probe and a leather carrying case with shoulder strap and belt loop.

For further information, contact *Non-Linear Systems, PO Box N, Del Mar CA 92014; (714)-755-1134.* Reader Service number N22.

The Model MS-230 Miniscope.

A CRITICAL REVIEW OF THE DRAKE UV-3

Drake's three-band VHF/UHF FM transceiver has gotten a good deal of attention and discussion. I've had one since Christmas, and I'd like to pass on comments about my experiences with it.

Vital Statistics

The UV-3 is a synthesized unit with 5-kHz steps. Coverage is all of 2 meters, all of 220, and 440 to 450 MHz. The unit can be ordered with any one band, any two, or all three. Built-in offsets are zero, plus or minus 600 kHz *on 2 meters*, plus or minus 1.6 MHz on 220, and plus or minus 5 MHz on 440. Up to three additional offsets may be programmed on a plug-in diode board, and the same three are shared between all bands. The frequency may be set up on front-panel switches, or up to four frequencies in each band can be diode-programmed. A master switch selects either the front panel or any of the programmed frequencies. The bandswitch is unconditional. There are *no* tune-up controls.

Each band uses a separate rf section, each adding 2½" to the depth of the case. Each band has a separate antenna jack. Maximum power is 25 W on 2 meters and 10 W on the other bands. The "low" setting of the power switch is about 10% of full power, and this can be changed by resistor substitution. There is a scan function which allows either programmed frequency #4 or the front-panel frequency to be checked every few seconds—momentarily interrupting the selected frequency—and locks in if carrier is present. A non-encoding mike is supplied, but the jack is wired to accept a Drake encoding mike. A mobile mounting bracket is included. There is an accessory jack.

Viewpoint

To make use of a theater review, it's necessary to be aware of the critic's prejudices and biases in order to put his comments in proper context. The same is true of a product review.

I take the attitude that any piece of equipment built for a serious purpose, of which repeater communication is sometimes a prime example, should have a set of features and specifications that follow with logical precision from that purpose. That is, it should do exactly what it's supposed to do.

There should be sufficient reserve performance to allow for expected component deterioration. It should be free of quirks that get in the way of its intended use or which require attention from the user beyond that which is inherently required by the function being fulfilled. It should be rugged, in the sense that conditions to be expected during use will not cause failure or degradation. It should be maintainable; assembly and disassembly needed to reach components should be easy, straightforward, and quick; parts should be readily available; and the design should be comprehensible, at least to the extent of avoiding peculiar tricks.

This is the standard by which a commercial workhorse is judged. There's an awful lot of ham gear around that wouldn't begin to measure up to that level. The first thing to say about the UV-3, though, is that it's a serious piece of engineering. The things that I will be criticizing probably would not even be mentioned in a review of a lesser piece of gear.

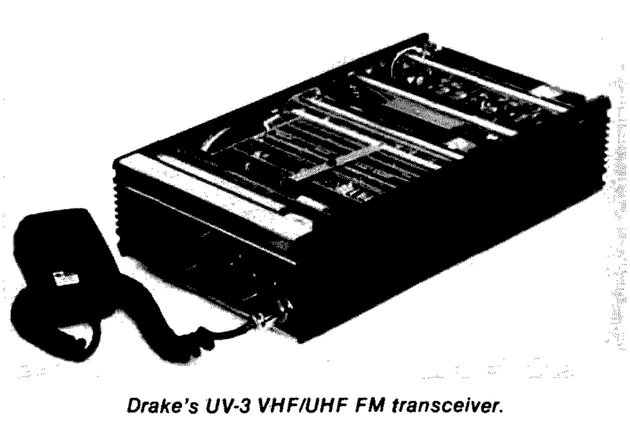
Performance

The UV-3's strong suit seems to be raw performance. There is no heterodyne synthesis; instead, a single vco for each band is retuned in going from receive to transmit. While I have not had the opportunity to check the spurious output specs with the spectrum analyzer, this approach tends to eliminate most spurs right at the source. The spec is −60 dB on 2 meters and 220, and −40 dB on 440. The lock range of the vco's easily exceeds spec; on the 2-meter band it held almost from 142 to 150 MHz.

Although the rf section is broadbanded and needs no tuning adjustments (except for dialing up the synthesizer), the output power was about 5% above specs across the rated bandwidth and didn't drop off too badly until the vco lost lock.

An apparent instability in power output turned out to be an effect of running off a storage battery with the charger turned off. Power is somewhat sensitive to supply voltage, but this is not a criticism. It just likes to be run off rated voltage, which is 11.5 to 15 volts. Incidentally, the negative side is grounded to the chassis, as are the antenna jacks. It requires a positive supply.

The audio is very good, to the point of attracting attention. I've repeatedly been asked, "That rig sounds pretty good; what is it?" To the ear, the response sounds smooth and distortion is not noticeable. There are no special audio shaping circuits; this makes it possible to wire the touch-tone™ encoder directly across the mike and have the correct twist relationship. On receive, the sound reminds the listener of the music receiver, allowing, of course, for the 12-kHz i-f bandwidth. The unusually large magnet in the speaker has to be one reason for this. If anything keeps you from communicating, it won't be the rig's audio. I



Drake's UV-3 VHF/UHF FM transceiver.

don't consider this a luxury; I do consider it a benchmark against which to measure other rigs.

Some highlights from the published specs:

Frequency accuracy—0.0005%, 0° to 60°C, 11.5 to 15 V dc.

Sensitivity—0.5 uV max., 12-dB SINAD.

Adjacent channel rejection—60 dB, 15 kHz away.

Image rejection—80 dB on the 140 band, 60 dB on the 220 band, and 55 dB on the 440 band.

While there is no spec as such covering overloading under very high off-channel field strength, the UV-3 is one of the few transceivers, ham or commercial, that doesn't misbehave going through the infamous "Intermod Alley" along Boston's Route 128. Intermod attenuation is given as −80 dB on 2 meters, −75 dB on 220, and −55 dB on 440. Figures like this don't tell the whole story because any receiver has an overload point at which the front end goes nonlinear and mixing begins. This one has a very high overload point; I have operated other transmitters near it without breaking squelch.

Construction

It's in the mechanical structure and assembly that the attitude of Drake's people shows most clearly. There is a great deal of attention to detail—detail that most other manufacturers might have skipped to save a few cents. I give Drake a lot of credit for resisting the temptation.

You won't find sheet metal screws in the UV-3. Pemnuts are pressed into the aluminum, giving a deep steel thread. Repeated disassembly won't damage any sheet metal parts. Lock washers are used freely inside, so screws are unlikely to shake loose in mobile operation.

Access to almost all of the insides is obtained by removing two screws at the back of the top cover and sliding the cover straight back along a pair of grooves in the side extrusions. The bottom cover comes off the same way, if necessary. There are ripples along the edges of the top and bottom covers which, at first glance, appear to be warpage in thin metal. When you look at the covers from the inside, though, it becomes obvious that those ripples were put there on purpose by a specially made tool. What they do is serve as springs, to wedge the covers tight in the grooves. That keeps down rattles at fairly high receive audio levels and most likely helps with rf shielding.

Most of the circuitry is built on epoxy-glass circuit boards which plug into a motherboard. These boards aren't going to crack if the rig gets dropped; there's a partial card cage to take care of flexing, and a hold-down is secured by a screw and the top cover. There was a little cost reduction here, but no real corner-cutting. The screw that holds the hold-down is about 1/16" too short so that it has to be backed all the way out to remove a card and tends to drop into the works. A board puller is stored inside in a clip next to the speaker. It's a simple type and has to be used carefully, but it cuts the risk of hurting a board or a socket.

The front panel carries no rf. It is removed by taking out four screws and pulling it straight out of the chassis. This is done when the remote control kit is used.

The rf modules are full of shielding and tight construction and don't look particularly easy to take apart in the field. A nice touch, though, is the accurate mechanical alignment of the side extrusions where the modules meet the main chassis and each other. There is no tendency for the top and bottom covers to catch at the joints.

The aluminum parts have anti-corrosion surface treatment, apparently Iridite. Outside surfaces are black anodize, black vinyl, or black paint.

Uses

The UV-3 fits in as a main desktop or mobile workhorse for dependable local communication. The design clearly doesn't contemplate operation while in motion on foot. While this is not wholly out of the question, it would require a lot of external accessories, and the rig is a pretty hefty hunk of hardware as well as a power-eater. The power requirements are targeted at car electrical systems and can be supplied easily from an ac-operated power supply. In emergency operation from a storage battery, or during very long periods of mobile operation with the engine shut down, there could be a problem. More about this later.

Drawbacks

There are a number of deficiencies in the unit that have nothing to do with its communication capabilities. These are failures of concept rather than of design or manufacturing.

Probably the most important is that the current drain on receive is much higher than it should be. This one spec is anything but state-of-the-art. It is 0.9 A. Almost half of this is used up by the dial lights that make the frequency switch settings visible. Thus, in emergency operation in a disaster involving general power failure, a battery small enough to carry easily to an operating position would be hard put to keep going for a day or two. A full-size car battery would be called for.

No method is provided for turning off the lights, and if the lights are simply disconnected to save power, the dark plastic window makes the dials almost impossible to read. As a stopgap measure, I cut a piece of 1/16" acrylic sheet the same size as the window (which drops easily out of its groove when the meter is pushed back against the mounting spring) to make a clear window and disconnected the lights. Unfortunately, this makes the 5 visible whether the last digit is zero or 5.

A better fix would be to glue a reed switch to the top edge of the lamp board just under the top cover, wired in series with the lights. Laying a magnet on top of the cover would then kill the lights and allow the use of the original window without using the lights—except to get on frequency. Drake really should do something about this. There should be a light switch at the very least, and putting in knobs that have markings out in the open would be better. As part of the latter, replacing the 0/5 toggle switch with a rotary like the rest would make operation a little easier.

This leads us to the way you change frequency on a UV-3—the same way you preflight an airplane. That is, you do a complete checklist, examining and verifying the position of *every* switch and knob on the panel. If you're only moving within the same megahertz, you can get away with just twisting knobs in the display row. Any more than that and you're likely to end up with the wrong offset, out of band, or not changing frequencies at all.

A few hours of thought about human engineering would have helped here. If the panel were as good as what's behind it, the frequency could be read unambiguously from one row of digits—band, offset, and all. And if the diode board and selector switch were retained at all, it would be obvious to the eye when the dial was disabled.

Another thing that didn't receive quite enough thought at the brainstorming stage is the remote control feature. Remoting, by itself, allows theft protection of the expensive parts by mounting the rig in the trunk or wherever else the owner's imagination and determination allow. However, security is only one of the purposes of remoting—the other is space conservation in the crowded front seat areas of today's cars.

The panel of the UV-3 is plenty big! Remoting cuts down on depth, but doesn't do a thing for the frontal area. I wouldn't particularly care to have a collision while a UV-3 panel was next to my legs, either. Using standard components, I figure a control panel could be made about twice the area of the end of a walkie-talkie and maybe 3 inches deep. Then if a blank panel were put on the main chassis with a recessed socket to take the miniature control panel, removal from the vehicle would be accomplished by unplugging the cable from the main chassis panel and popping the control panel into the chassis. This, incidentally, is not an unreasonable homebrew project.

Two of the features could just as well have been left out, to make space available for more useful things.

The first is the scan feature. When a carrier comes up on the priority scan channel, the voice you were listening to goes away in mid-word. I can hardly conceive of anyone wanting to hear everything said on some other channel in preference to the QSO in progress. Reversing the priority might make some sense, but monitoring another machine really requires a separate receiver. Also, whenever the frequency jumps to check the priority frequency and carrier is present on the selected channel, there is a short but loud burst of noise as the vco settles on the other frequency. This gets very annoying when it happens every couple of seconds and soon forces the user to shut the scan feature off.

This should not influence anyone's decision on whether or not to buy the UV-3. When a feature is useless in principle, it doesn't matter whether or not it works.

The other thing that could be eliminated is the diode programming. It was necessary on such early rigs as the IC-22S, but when any frequency can be dialed up directly from the front panel, internal diode programming is redundant. Elimination would also get rid of the confusion with the channel switch. If you do program the diodes, do it on a day when you have plenty of time, and use a good light and decent tools. Check your work thoroughly, or, better still, get somebody else to do the checking. The layout of the diode boards is such as to invite mistakes. One thing they did right was to supply diodes

Extremely Low Frequency Radiation: Cause for Worry?

—studies on ELF are inconclusive, but the battle is joined

Invisible health hazards may hang over America—radiation from high-voltage power lines.

Scientists and researchers worldwide are beginning to understand more about the effects of Extremely Low Frequency, ELF, as they call it. And some of these scientists are becoming concerned.

Most people believed, at the time when high-tension wires first appeared, criss-crossing and looping over our major cities and the countryside, that the electricity in the wires stayed there—that it did not leave the metal and pass through the insulation.

Now, of course, we know better. The flux set up by wires carrying high voltages is composed of two distinct forces: electric and magnetic fields.

We also know that these fields, at the right intensities, can reach us. But, unlike microwaves, which have been proven to be dangerous, little is known of the possible dangers of low-frequency radiation.

Presently, there are more than 100,000 miles of overhead high-tension lines in the United States which carry up to 765,000 volts at 60 Hz (50 Hz in Canada, 25 Hz in most of Europe). For the future, power companies are looking to lines carrying 1 million and 1.5 million volts—and that's what has many people concerned. The fluxes formed by such high voltages are enough to make your hair stand on end if you walk near them. And, if you hold a 40-Watt fluorescent bulb underneath a 345,000-volt line within about 100 feet of the line's right of way, it will light up.

Why do we need such high voltage? The answer is simple. The higher the voltage, the cheaper it is to transmit. Line losses are reduced as the voltage is increased.

Around 1967, realizing that the way to go was higher and higher voltages, studies funded by the American Electric Power Company and carried out by Johns Hopkins University looked at linemen who worked near high-voltage lines to see if they were being affected by the fields.

The linemen's health was studied, and so were some mice in the laboratory who also received exposure to similar ELF fields. Several of the linemen showed nominally low sperm count, but nothing conclusive. The mice seemed unaffected except that their progeny had slightly stunted growth. Again, however, the departure from normal fell within statistically acceptable limits. Even so, for most scientists and for the electric power companies, this showed a need for further experimenting and tests.

Then came Project Sanguine, a Navy project to build a huge antenna network covering hundreds of acres in Wisconsin. It was designed to transmit radio messages to submerged submarines throughout the world's oceans. The transmitting frequencies would be near those of an overhead power line—actually a bit lower, in the 15-20-Hz range.

The project was, to say the least, controversial. Environmentalists objected to it because it would literally rip up large tracts of land needed to bury the antenna. Others pointed to a study done by the University of Wisconsin which showed that ELF affected the physiology of a slime mold. Other studies done during Sanguine's planning stages also showed that ELF affected some lower organisms. The studies did not necessarily show ill effects, but they indeed showed a cause-and-effect relationship. Those studies, and citizen protests, were enough to table Project Sanguine.

Around this time, the late 1960s and early 1970s, a lot of other people started to get into the ELF act. For more than three years, New York State's Public Service Commission held hearings on the ELF situation. As a result of those hearings, packed by folks who didn't want a proposed 765,000-volt line running across their farmland, the PSC admitted that ELF presents some health threat to those who live and work near the lines.

The PSC did two things in response to its ELF hearings. It created an Administrative Research Council which would fund research on ELF's effects, and it widened the right of way of new lines from 350 feet to 1,200 feet. Right now, however, the Power Authority of New York is fighting the ARC on the grounds that

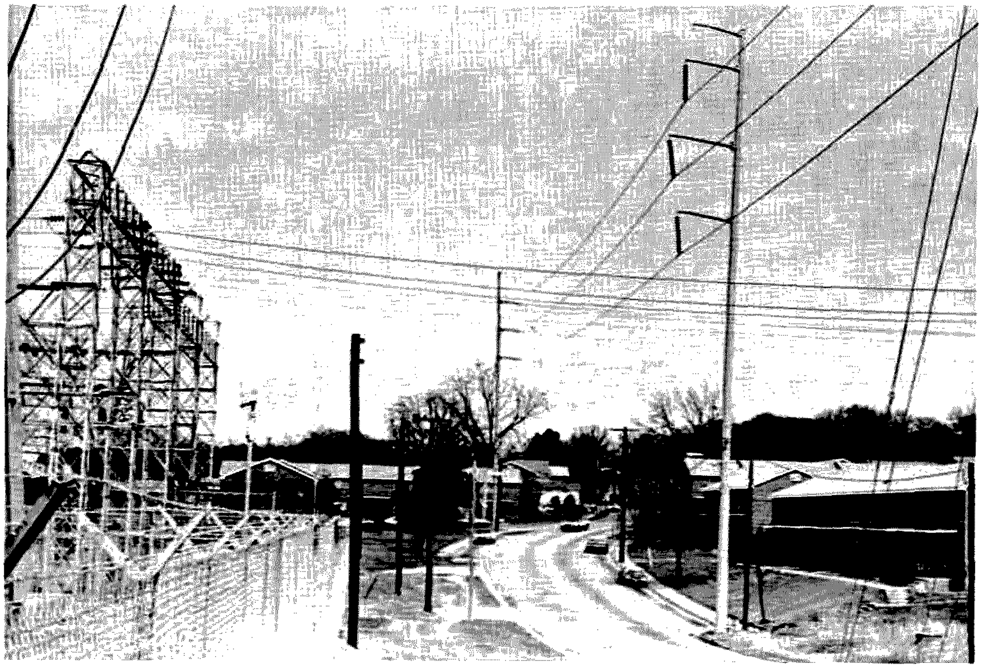
setting up a research group is not within the PSC's jurisdiction. The courts have not yet ruled on that point of law.

One of the more vocal speakers at the hearings was Dr. Andrew Marino, a researcher at the Veterans Administration Hospital in Syracuse, New York. "There is little doubt from the literature that biological changes do occur in humans exposed to high-tension wires," he said. Marino has been studying the effects of ELF on mice for about 3 years under a $75,000 National Institute of Health grant. In previous studies, he found that mice exposed to ELF had stunted growth. Results of his present studies have not yet been released.

The US Department of Energy has allocated about $3 million for high-voltage studies, and Bob Flugum, assistant director of DOE's Power Delivery Program, said that about $7 million is being spent on research throughout the world.

A famous study done in the Soviet Union showed that switchyard workers who worked near high-voltage equipment showed pulse rate changes and blood pressure fluctuations. It also showed that the men and women had tremors during or shortly after exposure. The studies were not conclusive, however, because only about 300 workers were studied — certainly not a large enough test sample. Even so, the Soviets have set maximum exposure standards for their citizens. The US has not. The Soviets, you may remember, also set standards for microwave exposure before the US government even acknowledged that the super-high frequencies were harmful.

"The most important proof that ELF alters biology is that some researchers



are using it to heal bones," said Marino. "There is no doubt it effects living organisms, but exactly what those changes are, we are not yet certain."

Dr. Harry Kornberg, a researcher for the Electric Power Research Institute in Palo Alto, California, is not as convinced as Marino that ELF affects humans. He said that work so far showing effects on humans and animals has been shoddy and not within good scientific procedure. EPRI is a research funding group sponsored by American utility companies, each of which gives the Institute money for its work. Kornberg said, however, that we are just beginning to see the start of what he calls "highly controlled, high quality, clinical testing."

Farmers will tell you that grass turns brown under high-tension wires, and just recently Penn State reported that leaf tips turn brown in the lab under similar conditions. Another recent study which Kornberg believes was done with good control was one at the University of Illinois. It showed that honeybees exposed to ELF build unusually small hives.

But Kornberg still disagrees that high-tension wires affect humans. "There have been no definitive studies which show it," he said. And he is correct.

No one has yet studied large groups of people exposed to ELF for long periods of time. Only then could we be certain that statistical and other laboratory anomalies did not creep into the results.

But even as scientists are beginning now to pull together all the information on ELF, and excellent studies are being done both in and out of the lab, a new wrinkle has been added — direct current. In an attempt to make power transmittal even more economical, power companies have begun experimenting with dc in voltages reaching over 1 million volts.

In case you haven't seen the papers in the past year, a battle over such a line has been brewing in Minnesota. The fight is between environmentalists and farmers on one side and the power companies on the other. A 400,000-volt dc power line was planned from North Dakota to the Minneapolis-St. Paul area. While the line's towers were being built, there was harassment allegedly from the farmers' side. They supposedly tore down towers and generally made life miserable for those building them.

Right now, the farmers seem to have lost the war. The line has been built and is now under test awaiting a power plant's completion in North Dakota.

Mike Casper, chairman of the Physics Department of Carleton College in Northfield, Minnesota, is writing a book about the struggle. "Very little is known about dc's effects at such high voltage," he said, "and the line, once in operation, will be the largest dc carrier in the nation." There is now one in California.

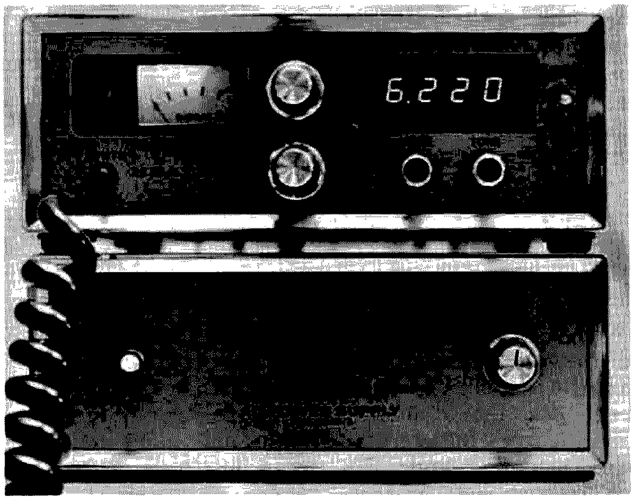
Casper, who has followed the fight from its inception several years ago, said that he expects to see continued guerrilla tactics from now until the 400-mile line carries its first electron . . . if it ever does. ■

An LED Display for the HW-2036

—eliminates unwieldy thumbwheel switches

Tom French WA4BZP
22044 Lakeland
El Toro CA 92639

Since I purchased and built the HW-2036, I have had only praise for the unit. However, after operating the HW-2036 for some time, I found the thumbwheel switches quite worrisome. It is almost impossible to see how to change frequency in the car at night and very difficult to get to the switches while driving. For these reasons, I decided to modify my 2036. When the idea for this modification was in its earliest stages, I knew I wanted to put the digital display in place of those awkward thumbwheels, but I did not know what to use to set the operating frequency. I knew an external box to enclose such a unit would look messy, and that went against my main objective which was to enhance the looks and capabilities of my HW-2036. Then the idea came to me to enclose a circuit board inside the Micoder™ that would do just that. It was neat, compact, and would make the Micoder able to switch frequency and also keep it a touchtone™ pad, just as before. The finished product has a very professional appearance and I think it will appeal to those who want to update their units to digital readout.



HW-2036 with digital modification installed.

Circuit Description

I decided to put common-cathode seven-segment LEDs behind a red plastic lens to display the frequency being used. I implemented the Fairchild decoder/driver because it drives the LEDs directly (Fig. 1). This means that dropping resistors are not needed from the driver to the display. In order to hold the BCD frequency and to feed it to the synthesizer board, I used SN74LS298s. These are quad two-input multiplexers with storage. The zero—or five-kHz digit is developed by a BCD-to-decimal decoder. This, in turn, is fed to an inverter for conditioning and then to a five-input NOR gate for the final 0/5-kHz output signal. This signal is connected to pin X on the synthesizer circuit board.

The microphone cable can be replaced with a new one that has at least twelve conductors. I revamped the Micoder so that it is a touchtone pad in the transmit mode, and so that the operating frequency can be selected in the receive mode (Fig. 2). Three chips were installed into the 2036-MB (MicBoard). The NE555 was used as a clock generator for the MC14419 keypad-to-BCD decoder. The MC14410 keypad tone integrator is also installed on this board. The original microphone element is retained but I added a 2.2k resistor from the original Micoder board. Two 7805 voltage regulators were added to supply the necessary voltage for the additional circuitry (Fig. 3).

Chassis

To accomplish the modifications, proceed as follows: Remove all the covers and knobs from your 2036. Care should be

taken not to ruin the synthesizer lock LED as you separate the front panel subplate and bezel. Next, remove the thumbwheel switches and save the four supporting screws and nuts. Fit the red plastic window over the thumbwheel switch window and mark the locations for the four holes that you will drill to accommodate the previously-removed supporting screws. On the side of the window where the 0/5 switch is located, a small notch should be filed in order for the nut (that holds the 0/5-kHz switch to the subchassis) to clear when assembled. Two #6 screw holes have to be drilled to hold the 7805 regulators against the subchassis. The first hole should be drilled beside the speaker and below the synthesizer board. See Fig. 4. To get to the second hole, you will need to pull the power amplifier board a few inches away from the back panel (Fig. 5). Drill these holes with care and do not let shavings fall near the boards. Install both 7805 voltage regulators as illustrated in Figs. 4 and 5 using silicone grease. Then reinstall the power amplifier board.

Now remove the microphone cable from your rig. It will be replaced by a 12- to 24-conductor cable. Place some type of insulation over the speaker connections and side magnet, preferably electrical tape. This will keep the snug-fitting 2036-DB (display board) from shorting on the speaker. The display board should be on a horizontal plane with the bottom of the display window. Use a plastic washer on the rear and front mounting hole of the 2036-DB. This will keep the mounting screws and nuts from shorting the bottom of the circuit board. Use 6-32 × 1¼" countersunk mounting screws for the 2036-DB (Fig. 4).

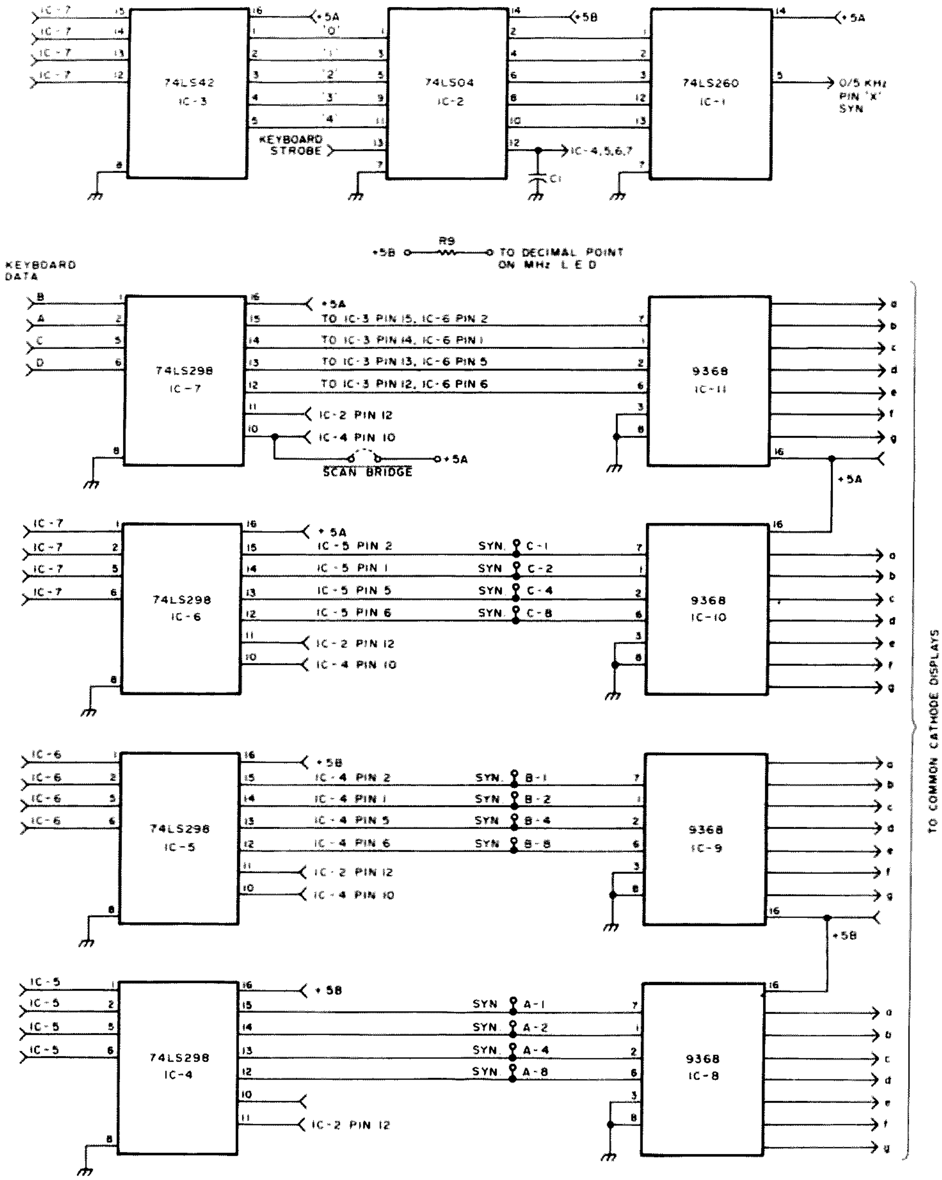


Fig. 1. 2036-DB Display Board schematic.

MicBoard 2036-MB

Disassemble the Micoder completely by unsoldering all the wires and by removing the board. Clean the terminal strip of all solder and wire. Retain the 2.2k resistor and join it to one of the microphone element leads. Connect a ground wire to the microphone element ground. The remaining lead is connected for audio output. See Fig. 6. Remove the pin sockets from your old Micoder board and reinstall in the new 2036-MB. These are the pin sockets that will hold the keypad. Put the chips in on the component side. Do observe correct pin locations. Connect pin 8 on the MC14410, pin 8 on the MC14419, and pin 1 on the NE555 to the ground plane. Notice that the .01-uF and .047-uF capacitors are electrolytic, so observe the correct polarity. The only parts that go on the underside of the board are the 1 MHz crystal and the .01-uF clock capacitor, if the disc type is being used.

After all parts are set up on the 2036-MB, follow the correct cable color code for interconnection to the 2036 (Fig. 7). On the 24-conductor microphone cable that I used, the end with pin connectors should go in the microphone housing.

Connect one wire to +5 V dc on receive, one to +5 V dc on transmit, one to +5 V dc, one to ground, and the last to audio output—all on the 2036-MB. The +5 V dc on transmit is labeled pin 3, +5 V dc on receive is pin 1, and audio output is pin 2. The +5-V dc power for the 2036-MB is acquired from the 7805 IC-1 originally in the rig.

Display Board 2036-DB

Molex pins may be used as well as low profile

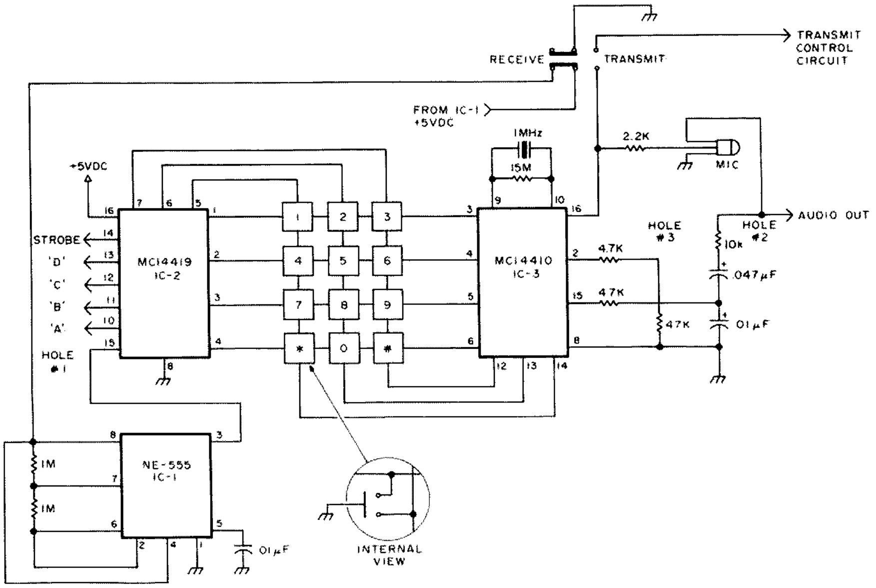

Fig. 2. 2036-MB MicBoard schematic.

sockets on this board. Install the sockets or directly install the chips. Install 220-Ohm, ¼-Watt resistor R9 to make the decimal point connection. Capacitor C1 is only installed if triple or double digiting is encountered when you key in a number. The value of this capacitor is dependent on whether or not the SN74LS298 chips match. The capacitor should be somewhere in the range of 100 uF to 470 pF. If desired, SN74LS48 BCD-to-seven-segment decoder/drivers may be employed instead of the 9368s, by running 2k pull-up resistors to the LEDs. When using the SN74LS48 chips, pin 3 of the decoder/driver should be clipped off, as the lamp test function is not used. (To test all lamps, just key in four eights in a row.) Using the pull-up resistors in this fashion makes for a rough time when you take the decoder/driver chips out and does not accommodate my scanner option board. (See Fig. 8 for pinouts on both chip styles.) From the synthesizer circuit board, remove all of the pull-up resistors associated with the thumbwheel switches: R401-409 and R411-413. Make a small solder bridge with a piece of wire at the scan bridge to pin 10 of IC7 if you are *not* using the scan option on the 2036-DB.

Resolder the wires from the thumbwheel switches to their corresponding display drivers. For the MHz, use IC8 pin 7. This is BCD "A", which goes to synthesizer circuit board pin A1. IC8 pin 1 is BCD "B", which goes to synthesizer pin A2, and so forth. IC9 is used for the hundreds of kilohertz and IC10 is used for the tens of kilohertz. IC11 remains to display the one-kilohertz digit. Remove the wiring from the 0/5-kHz switch completely. Put in the 0/5-kHz wire to the corresponding location on the 2036-DB. You will have to make a small five-wire bundle, eight inches long, out of the wires in the microphone cable to make the strobe and the BCD connections from the microphone cable to the 2036-DB. This wire bundle does not have to be shielded, but should be run under the volume and mode switches.

Install the 25-uF, 25-V dc and .01-uF capacitors on both outputs of the 7805 regulators. Connect the rear 7805 to the +5B power hole and the front 7805 to the +5A power hole. Install the ground wire connection to the 2036-DB at this time. The common-cathode LEDs that you choose can be socketed. Align all four sockets on a flat surface and "super glue" them together. Install the 2036-DB and, with a pencil, mark on the board the width of the display window opening. Remove the board and "super glue" the four sockets in the center of the marked display opening and to the rear of the board as far as possible. Keeping the sockets to the rear of the board will prevent the LEDs from scratching the red plastic lens. Remove the pins not used by the LEDs. Wiring from the sockets to the board should be accomplished by using wire-wrap.

Checkout

After I completed all connections and reassembly, I tested my modifica-

tion. I started with the 2036-MB. With power on, the display should show random numbers and sometimes letters. I checked pin 8 of the NE555 for +5 V dc, and also pin 16 of MC14419 for +5 V dc. If this checks out, you may assume pin 3 of the 555 is generating a clock pulse. This pulse is used to generate the keypad strobe upon depression of a keypad number. The # and * are considered invalid digits, and, therefore, they will not generate a bit pattern when the operator selects a frequency. After depressing a valid digit, I looked for a short strobe pulse, one that goes from low to high and back to low. The BCD digit will be on the output lines as long as you hold your finger on the pad. Keypad data is fed to IC7 upon receipt of a keypad strobe pulse. It is then shifted in or out to the next stages, IC6, and so on. For IC7, which is the kHz digit, the BCD signals are sent to a BCD-to-decimal converter (IC3). This will send a logic one out if the BCD input is between zero and four, and a logic zero will be sent if it is between five and nine. IC2 inverts the signals which are then sent to a five-input NOR gate for the final 0/5-kHz output. A logic zero equals zero kHz and a logic one equals a 5-kHz signal.

Audio generated by the keypad-to-tone integrator MC14410 is coupled directly to the audio input line. In most units with this completed modification, the transmitter deviation needed to be lowered. It is advisable to check your deviation and set it to not more than 5 kHz.

To display the operating frequency of 146.820 MHz, simply touch in the digit sequence 6, 8, 2, 0 on the keypad. The same is true for 147.855 MHz; the digit sequence would be 7, 8, 5, 5. When the push-to-talk

switch is depressed, the keypad is now a touchtone pad. Be careful not to hold your finger on a digit and then let go of the push-to-talk switch—you will find yourself on some other frequency.

Conclusion

This modification has been on my HW-2036 since April, 1978, and I appreciate the rig more each day. It works beautifully, and really is pleasing to the eye. The maximum overall cost for project parts should not exceed $65. The EK-2036 kit, which can be purchased from Data-Signal, Inc., includes a 1-MHz crystal, a MC14410 touchtone encoder, and assorted discrete components. There is another option board which allows the HW-2036 to scan any 1-MHz segment of the band and stop on any carrier. A small push-on only switch is added at one side of the microphone to cause scanning to continue. This works fine for those units that are not plagued by birdies at various divisions of one MHz.

The MicBoard (2036-MB) and Display Board (2036-DB) can be acquired by writing directly to me. These boards are double-sided and plated through. The price for two boards and an instruction booklet is $16.95. For the intrepid constructor, PC board layouts for the two boards are shown in Figs. 9 and 10.

My thanks to Jim Bell K4FUP for the accompanying photograph. ■

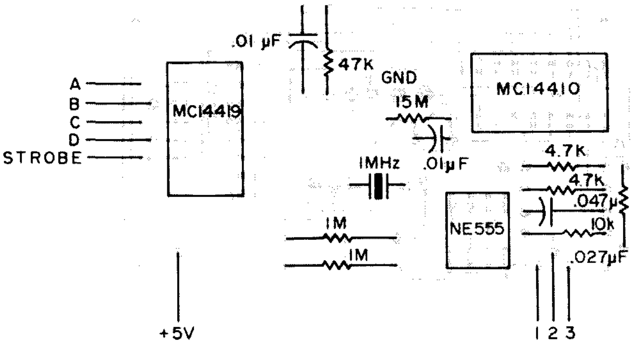
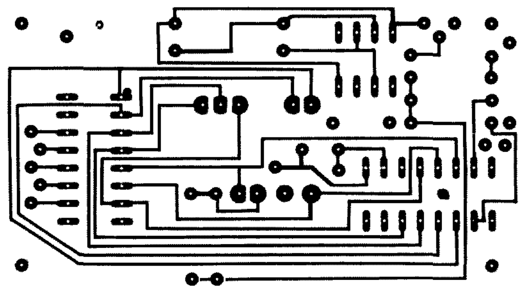
Fig. 10. PC board layout for the 2036-MB board. Left view shows component side; right view shows other side.





It's a Wattmeter . . . It's an Swr Bridge . . . It's Swattmeter!

—a super home-brew project

A. R. Pedrick K4LBY
1446 Hagen Lane
Rockledge FL 32955

One of my favorite pastimes in amateur radio is designing and building antennas for the HF spectrum. I have a 5-band trap vertical mounted 12" above ground, a ground plane vertical on the roof, a 10-meter "sloper" which is part of my TV guy-wire system, a 3-band inverted "vee," also part of the guy-wire system, and a couple of experimental 3/2-wavelength wires on the roof.

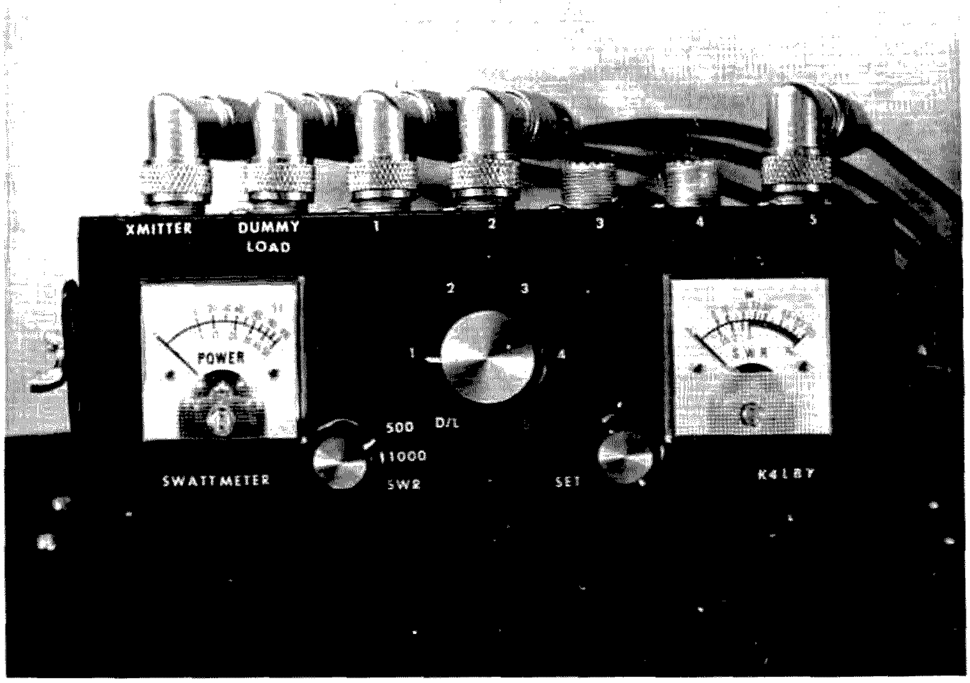


Photo A. The Swattmeter is mounted in station operating position. The meter on the left reads forward power. Reverse power and swr are shown on the right.

Now, I am working on a miniature quad, hoping I can find room to mount the thing. All this means that PL-259 coax connectors by the barrelful are coming into the shack. Of course, the only practical way to compare the relative performance of all these antennas is to use a husky coax switch so that I can readily go from one antenna to another during a QSO, and hopefully get some meaningful reports from the guy on the other end without making him wait until I disconnect and reconnect coax cables.

With this thought in mind, I recently acquired a B&W Model 595 coaxial switch which is a 6-position in-line model designed for wall or desk-top mounting. I preferred the in-line ar-

rangement to the axial configuration, in order to keep the thing from looking like an octopus squatting on the shelf.

Once I had the switch in hand, I started to think about all the other outboard stuff I had connected between my transceiver and the antennas. There was, of course, the low-pass filter, then an swr meter, and finally a borrowed power meter. Now, with the switch in place, the shack was beginning to resemble something out of Rube Goldberg. Besides the fact that it looked like a mess, did you ever have the need to determine just how long your transmission line is for matching purposes? Some of my antennas load best when the transmission line length is in multiples of 45'6" for RG-58/U. Outboard devices are handy, but just how much length does a switch like the B&W add, anyway? (I'll admit that the length added by any one outboard device is negligible, but I'm a nitpicker. And when you add two or three other gadgets, you start talking feet, not inches.)

Needless to say, the B&W came apart, and I discovered that the effective transmission line length was variable, depending on the position of the switch. Fig. 1 shows how the switch is wired as it comes from the factory.

When the switch is in positions 1 or 6, the effective length is the shortest, and in positions 3 and 4, the longest. As I said before, it probably does not mean much as a matter of practical fact, but what did matter was something else I noticed: There was a lot of wasted space in the guts of that switch! The space, in fact, looked tailor-made to contain a couple of meters and the necessary components for an swr/power bridge.

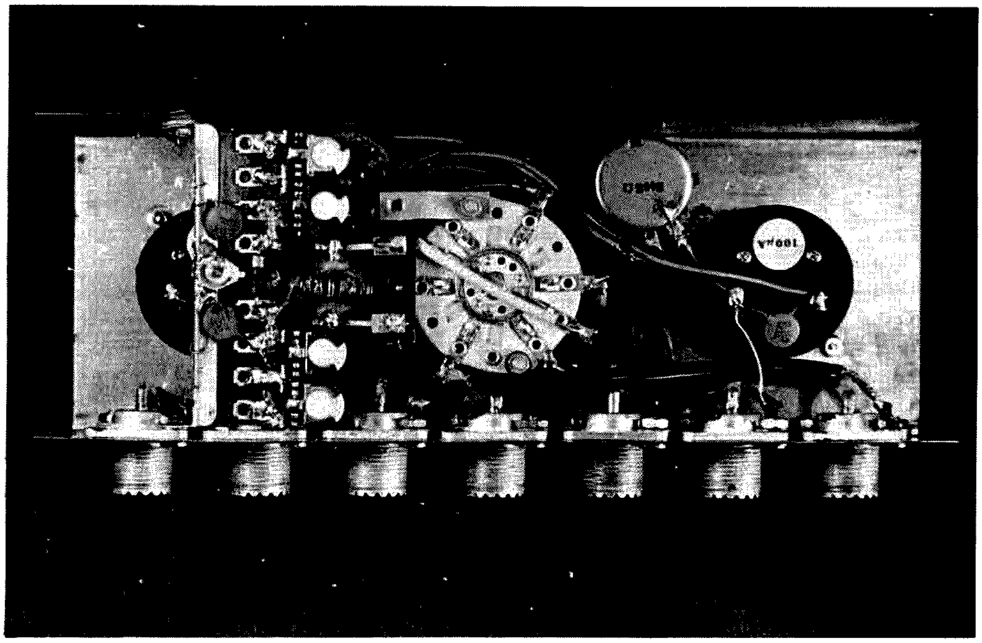

Photo B. An inside view of the Swattmeter. The SO-239 connector on the left is the input.

And so the Swattmeter was hatched, which is really what this article is about (I do ramble, don't I?). Line length forgotten for the moment, I took off after this new idea like a hound sniffin' grass, much to the exasperation of the XYL.

You might ask, why bother? Well, it's neater and results in less junk outboard from the transceiver. Besides, it looked like a challenge, and then there's that line-length factor . . .

Description and Criteria

The accompanying photographs pretty much show how the Swattmeter is constructed and what went into it. There is really nothing new in its design, but, rather, a circuit modification or two. The wattmeter portion of the Swattmeter uses the 100-uA dual meters cannibalized from the Swan model SWR-1. Also cannibalized from the Swan is the dual 10k potentiometer used for swr "set." What is different from the Swan meter is the toroid current transformer used as the directional coupler, rather than the transmission line-type coupler used in the Swan and similar inexpensive swr meters. I used the meters from the Swan because I had them, and they were already calibrated in terms of power and swr. Of course, any 100-uA meters may be used. The only criterion is that they fit into the space on either side of the switch.

Fig. 2 is the schematic of the Swattmeter. You will see that, with some exceptions, the circuit is similar to one described by Bruene in *QST* (April, 1959). The bridge circuit by Bruene uses a capacitive voltage divider and a current detector to provide two voltages proportional to the forward and reflected voltages or currents of the transmission line. See Fig. 3.

The circuit in Fig. 2 uses the stray capacitance between the current transformer and the line as part of the voltage divider. Most bridge designs try to eliminate stray capacitance so that a controlled amount can be used in the design. I figured, why fight it? I coudn't figure out how to shield everything in the confines of the B&W switch, and "if you can't lick 'em, join 'em!" The variable 6- to 20-pF ceramic trimmer of Fig. 2 is the other half of the voltage divider.

The design here uses a bifilar-wound current transformer in which the low impedance at the secondary is split into two equal parts. The center tap on the transformer is also part of the voltage sampling network (stray capacitance plus the 6- to 20-pF trimmer) so that the sum and difference voltages are available at the ends of the transformer secondary winding. With the values shown, the meter maintains its calibration to within 10 percent over the frequency range of 3 to 30 MHz—and probably from

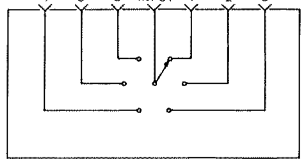

Fig. 1. Simplified wiring diagram, B&W Model 595 coaxial switch. Note: Automatic grounding (not shown) of all unused positions is incorporated.

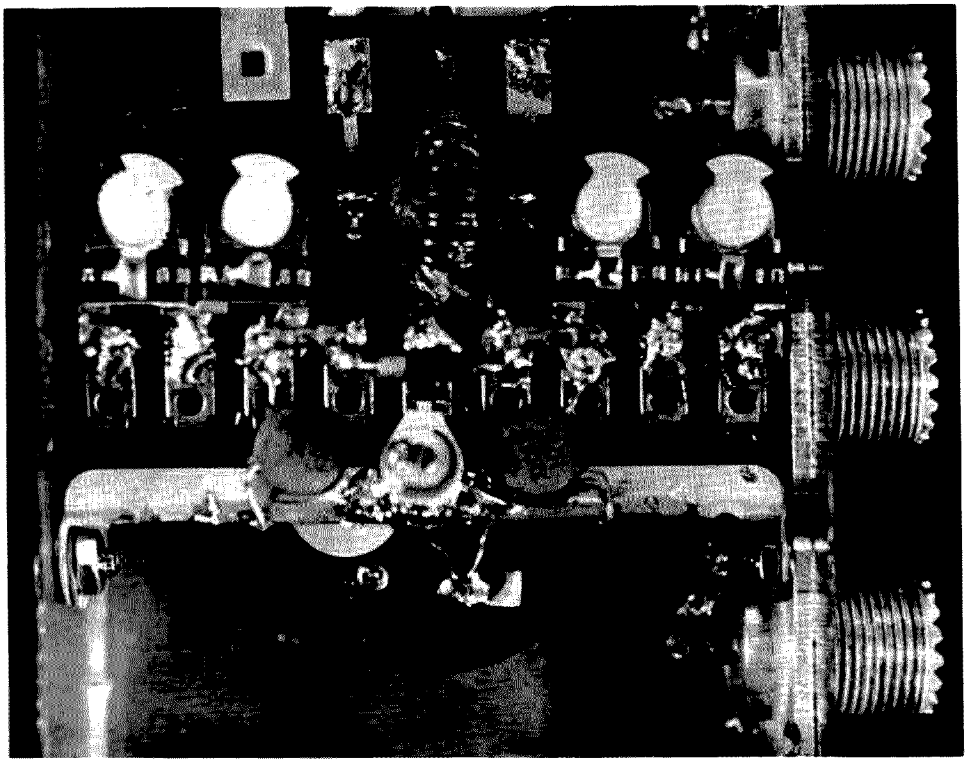

Photo C. A closeup view of nine-lug terminal strip and current transformer. The input SO-239 connector is on the lower right.

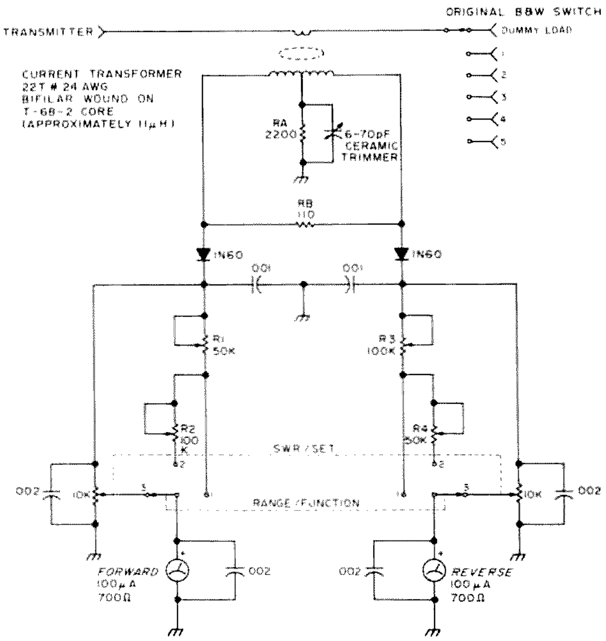
1 to 50 MHz, although I have used only the former. The degree of isolation between forward and reverse readings into a matched dummy load is excellent (estimated to be between 20 and 30 dB). I can pump nearly 500 Watts of rf into a 50-Ohm dummy load through the Swattmeter with nary an indication of reverse power.



RANGE/FUNCTION

POSITION	FWD	REV
1	500W	100W
2	1000W	1000W
3	SWR SET	SWR

Fig. 2. Swattmeter schematic.

A three-position switch is used as a function/range selector allowing for two power ranges and an SWR position. Position 1 of the switch allows forward power measurement of 500 Watts and reverse power of 100 Watts. Position 2 reads 1000 Watts forward and 1000 Watts reverse, and position 3 is for standard swr measurements using the "set" control variable potentiometer to calibrate the left-hand meter in the conventional manner. Swr is then read directly from the right-hand meter. Alternatively, the "swr set" potentiometer dial also can be calibrated in Watts if desired. When the function switch is set at swr and the pot is wide open, maximum sensitivity (both forward and reverse) is less than 5 Watts full scale.

The wattmeter can be made more sensitive by increasing the number of turns on the toroid. This causes the inter-turn capacitance to increase, however, and causes the response to fall at high frequencies. Consequently, the directivity also falls. The values of R_A and R_B were determined experimentally and can vary by 10%. R_B should have a value of 150 Ohms if the Swattmeter is to be used predominately with 72-Ohm cable. The values shown are good for 50- to 53-Ohm coax.

The 1N60 diodes need to be matched for both forward and reverse resistance. They should be within 5% if possible, with the forward resistance more important than the reverse.

A word here about bypass capacitors is in order. Use good quality ceramic capacitors rated at 1000 volts. Some ceramic capacitors act as fine inductors, especially at the higher frequencies, and can cause all sorts of spurious readings. This is particularly important in the confined space available in the B&W switch body, with all that rf bounding around inside. With good capacitors, noninductive resistors, and the layout shown, you should have no problems.

Construction

Assuming you have all the parts handy, the first step is to *completely* disassemble the B&W switch. I removed even the SO-239 coax connectors by drilling out the rivets in order to allow ground lugs to be mounted, one at each connector. The reason for this will be evident later on (remember the original line-length problem). Besides, the paint job on the 595 didn't please me, and I wanted to refinish the thing once I got the meter and control holes drilled.

The layout is tight but

workable, and depends pretty much on the size of your meters and other components. The meters I used mount in a 1½-inch diameter hole (which was convenient, since I happened to have a Greenlee punch just the right size). Needless to say, but I'll say it anyway, *check all dimensions carefully*. You get only one chance for proper clearances.

Once all the holes are drilled, the original finish can be removed (your option) with lacquer thinner, and the unit primed and refinished. I used Walsco Collins Instrument charcoal gray wrinkle varnish which comes in a convenient spray can.

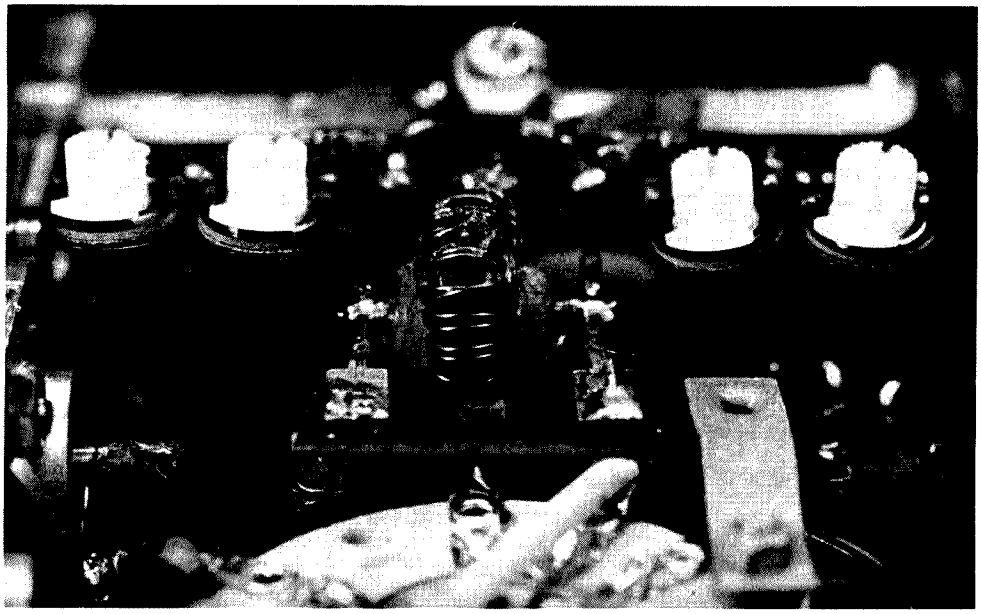


Photo D. Detailed view of the two-lug terminal strip and current transformer.

Once the paint is dry, you may wish to apply the panel markings before the components are mounted. It is easier if you know what you want and where you want it. Dry-mount lettering is easy to apply even to wrinkle finish, but should be sprayed afterwards with a clear finish to protect the lettering. I usually do it the hard way, and put the markings on last just in case I want to change something at the last minute.

The SO-239 coaxial chassis connectors should be mounted using 6-32 hardware with lock washers and a ground lug for each connector. Make sure there is no paint on the inside of the case, which may cause a poor metal-to-metal contact. Mount all the other components as shown in the photos, except for the nine-lug terminal strip. (It will be mounted after the switch has been wired.)

First, after all the hardware is secure, wire the coax switch. The input to the switch is now the first SO-239 connector on the left. This was done to allow room for the current transformer. All output connectors were wired to the switch in a clockwise direction using 5" lengths of RG-58C/U, which is more flexible than the others. The outer conductor of each length of coax is grounded to its respective SO-239 ground lug, but stripped back out of the way on the end which connects to the switch. This provides for shielded leads *all the same length* within the Swattmeter (I told you we would get back to that) and enables the switch-wiring to be routed easily out of the way of the other components. The effective transmission line length of the switch when wired in this manner is approximately 1 foot in all positions, give or take an inch.

Don't forget that the B&W switch actually has two decks, one of which grounds all unused positions. In the original switch, this second deck was grounded at the switch at a lug on the switch spacer. I preferred to eliminate that lug and ground the second deck to the nearest SO-239 ground lug.

The input side of the switch uses a 3" length of RG-58C/U, prepared as above and fastened to the input SO-239 in the same manner as the other cables. The exception is the other end, which goes to one lug of a two-lug terminal strip as shown in the photo. The second lug of the terminal strip is wired with bare wire to the input terminal of the switch.

You may have to improvise a little with this two-lug terminal strip, which is used to hold the toroid transformer. I found mine in my junk box and it was a perfect fit.

As you can see in the photos, the current transformer is slipped over a short piece of RG-8/U center conductor and the stripped ends of the RG-8/U are then soldered to the two-lug terminal strip. Fig. 4 illustrates a little more clearly how this is done. The physical configuration of the terminal strip lugs and the RG-8/U inner conductor acts as a half-turn loop, or primary, for the toroid. Actual dimensions are not critical, but the wiring to and from the terminal strip lugs should be soldered at the base rivet of each lug and *not* where the RG-8/U center conductor is soldered. The toroid is held in place by a few dabs of silicone cement.

The current transformer is wound on a T-68-2 (red) core which is rated for use between 1 and 30 MHz. Cut two pieces of no. 24 enameled wire about 60 cm (24") long. Put two ends together in a vise and twist until you have about 1 twist per cm (2½ twists per inch). Wind 22 turns on the toroid, leaving about 2½ cm (1") out of the toroid on both ends of the

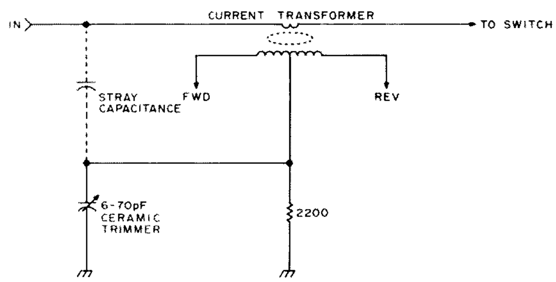

Fig. 3. Capacitive voltage divider with current transformer.

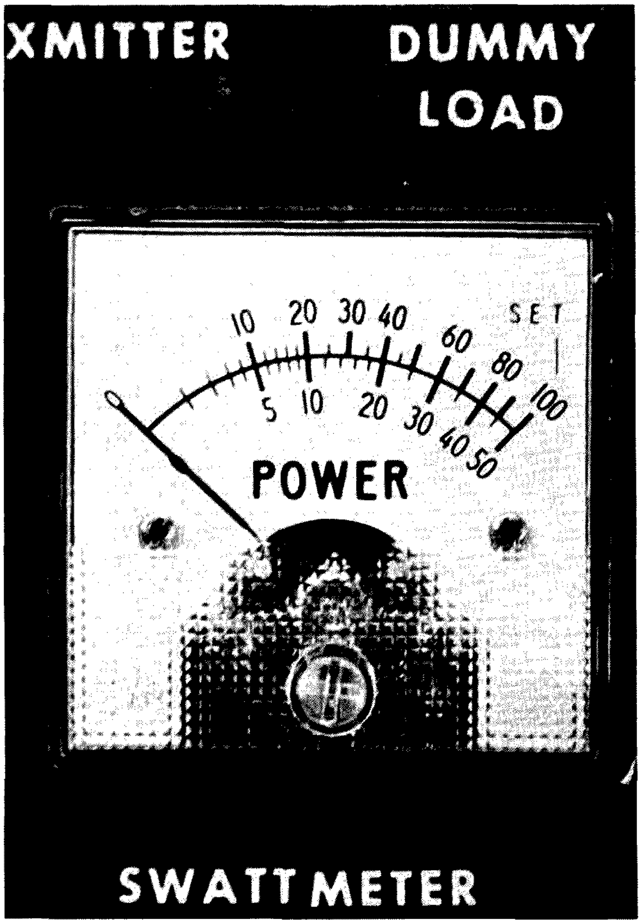

Photo E. Calibration of forward power meter.

winding. The turns should be close-wound around the inner circumference of the core, and evenly spaced along the outer circumference.

Carefully remove all the enamel back towards the toroid, select a wire from each end of the winding, and test with an ohmmeter to find two wires that do not show continuity. Connect these two wires together and hold with a drop of solder. This is the center tap. Check for continuity on the two remaining wires. The result is two bifilar windings in series, with a center tap, or 44 total turns. Total inductance is approximately 11 uH.

The toroid coil should then be slipped over a short length of RG-8/U coax with the outer insulation and braid removed, and mounted and soldered to

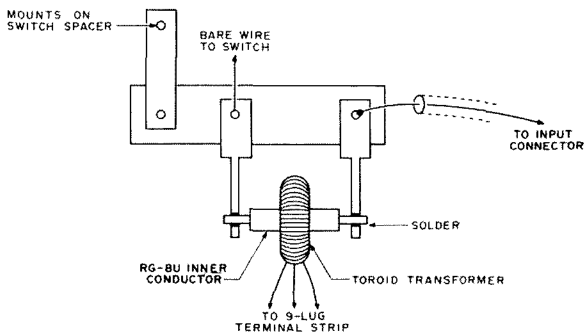

Fig. 4. Mounting the current transformer.

the two-lug terminal strip as described above.

After the toroid is in place, the rest of the Swattmeter wiring is conventional. Wire the hard-to-reach items first, such as the meter bypass capacitors and leads, which are located under the seven-lug terminal strip once it is installed. I used a series 3000, nine-lug terminal strip with a cadmium-plated steel mounting base for point-to-point wiring (available from Allied/Radio Shack). I did consider a PC board, but decided against it since the wiring is so simple. Also, the steel mounting base of the terminal strip makes a fine balanced ground point, as you can see in the photos.

The mounting holes on the terminal strip are bent at right angles away from the lugs. One side is mounted under the bottom nut holding the first (input) SO-239 connector. The other side is secured with 6-32 hardware through a hole drilled in the front of the enclosure. *Use lock washers between the terminal strip mounting holes and the steel enclosure/SO-239 connector,* as well as under each nut.

The center lug of the nine-lug terminal strip is the junction or tie point for the toroid center tap. The 2.2k resistor should be mounted on the underside of the terminal strip, using short leads. Use the metal base of the terminal strip as the ground point. Similarly, the 6- to 70-pF ceramic trimmer capacitor is mounted on the top side of the terminal strip. Again, use the metal base of the terminal strip just opposite of the center lug as a ground point for the capacitor.

Do not connect the two outer wires of the toroid until all other wiring is completed. You will have to determine by trial which lead is forward and which is reverse.

Use short leads for all bypass capacitors, and ground at the closest point possible. *Do not add additional capacitors.* They aren't needed and could make problems. Route all wires from and to the nine-lug terminal strip *under* the terminal strip away from the toroid. Make the layout as uniform and symmetrical as possible. The last components to be soldered in place should be the trimpots used to calibrate the two power positions of the function switch. Fig. 5 and the photos show the location of these trimpots.

I used the miniature pots available at Lafayette because they were the smallest I could get my hands on inexpensively. I cut off the center connector of each pot, and made a solder bridge from the remaining part of the center lug to one side of the pot to conserve space. All four pots are held in place with solder. Forget the old adage of a "good mechanical connection." "Solder is enough," is my motto.

Setup and Calibration

Assuming that all other wiring is complete, tack-solder the two remaining toroid wires to the terminals as shown in Fig. 5. You have a 50/50 chance of getting it right the first time, but Murphy's Law is still in effect, so don't count on it.

Now comes the "smoke" test. Hook up the input connector to an rf source of at least 5 Watts and a 50-Ohm dummy load to one of the output connectors. *Make sure the Swattmeter switch is in the appropriate position* or else there will be smoke, and it won't be coming from the power meter! (Don't ask me how I know!)

Set your rf source, transmitter, or transceiver

on 10 meters and the Swattmeter function switch to SWR. Run the swr meter "set" pot up full clockwise, and key the transmitter. *A lot of power is neither needed nor desired at this point.* Use a rf output level that you can comfortably maintain for a period of time without worrying about your finals sagging.

If all has gone well, the forward power meter (on the left) should register, and the reflected power meter may or may not register. Carefully and slowly, adjust the 6- to 70-pF trimmer capacitor and watch the meters for results. If the toroid is connected correctly, the reading on the reflected power meter should null out. If the null is experienced on the forward side, reverse the toroid connections and try again. Use minimum power and try to hit the null square in the middle. You will find that the null is fairly sharp on 10 meters, but gets broader as the frequency is reduced. Not to worry. Once balanced at 28 MHz, the bridge is okay at all other frequencies.

At this point the bridge is balanced, and all we have to do is calibrate the two power positions. If you have used meters which are calibrated at 0-100 uA, calibration for power will be nonlinear because the meter samples voltage, whereas power is proportional to voltage squared. Table 1 shows the relationship between a 0-100 linear meter scale and power. Two power ranges are shown: 0-50 Watts and 0-100 Watts. The meters I used were already calibrated in terms of power and swr (from the Swan SWR-1), and the power ranges were calculated to match the existing scales.

If you have to use meters calibrated at 0-100 uA, you can use Table 1 to determine actual power and swr, or you can remake the linear scales using dry-transfer press-on lettering. It isn't really all that difficult. Calibration is a heck of a lot less difficult if the meter scales read power instead of microamperes.

There are at least three ways to calibrate the Swattmeter. In each case, the wattmeter is calibrated by feeding power through the meter into a dummy load. It also is possible to infer calibration by measuring the dc output of the forward detector, which can be measured with a high-impedance dc voltmeter (more on this later). In all cases except the last, the reflected power meter is calibrated by reversing the external connections to the coaxial line.

The first method is to beg or borrow another wattmeter to use as a calibrated reference. Simply connect the borrowed meter in series with the power meter between your transmitter and dummy load. Set the range switch to 0-500 Watts and crank up your transmitter for a 10-Watt output as indicated by the borrowed meter. Adjust R1 for a 10-Watt indication on the 0-50 scale of the power meter. Move the range switch to 0-1000 Watts and adjust R2 for a 10-Watt reading on the 0-100 scale. Reverse the coaxial connections to the Swattmeter and calibrate for reflected power in the same manner, using R3 first for the 0-100-Watt position, and R4 for the 0-1000-Watt position.

The second method requires an rf voltmeter and measuring the power dissipated in the dummy load by measuring the rf voltage across the load. However, most rf probes designed for use with com-

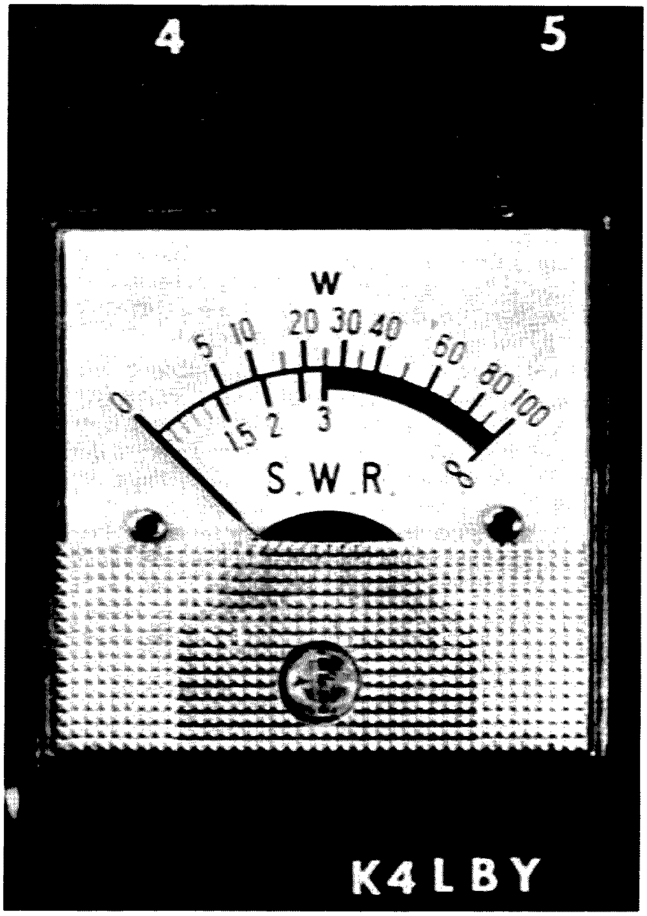

Photo F. Calibration of reverse power and swr meter.

mercial VTVMs are strictly limited. The reason is that the peak reverse voltage appearing across the probe diode will exceed the diode breakdown rating for a peak rf power of much over 10 Watts. (Ten Watts rf across a 50-Ohm dummy load will produce about 22.4 volts dc.) Fortunately, all we need is one bench mark if we assume the wattmeter to be reasonably linear; and a 10-Watt bench mark is as good as any.

An alternative is to use a voltage divider, say 10:1, in front of the diode detector, but that messes up the total load since the voltage divider then appears in parallel with the 50-Ohm dummy load. You can do it if you want to recalculate the load, for example, but it really isn't necessary. The Swattmeter isn't meant to replace a really

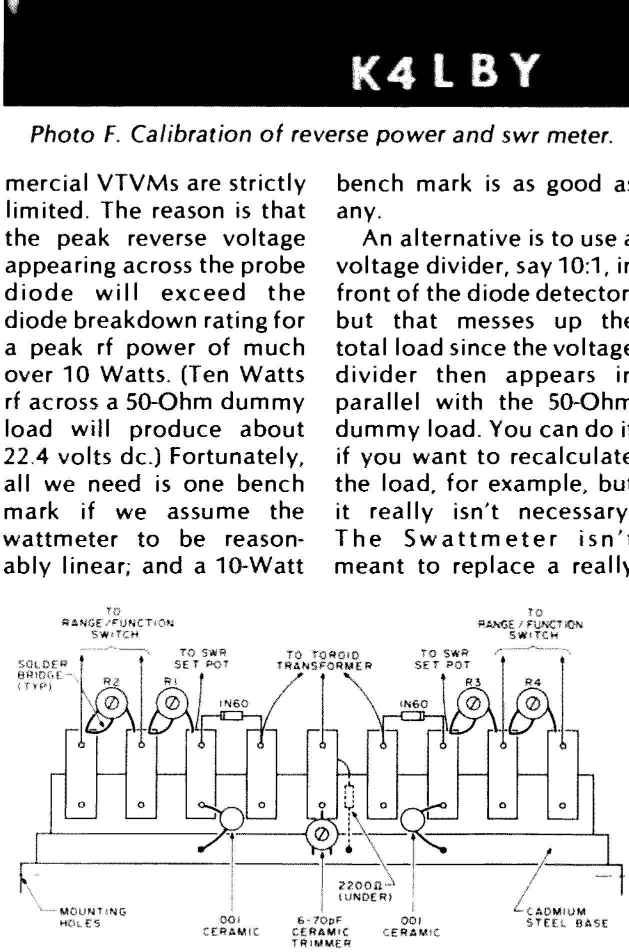

Fig. 5. Wiring diagram, nine-lug terminal strip.

good high-accuracy wattmeter in the first place.

The procedure using the second method of calibration is the same as outlined above, using a second wattmeter. The reference, however, is your VTVM rather than the borrowed wattmeter. Connect your VTVM with the rf probe across the 50-Ohm dummy load. (It won't hurt to measure the actual resistance of the dummy load first, since it may vary between 40 and 60 Ohms, especially if it has been well-used over a period of years. Even good quality resistors change value as they are heated and cooled periodically.) Adjust your transmitter drive to produce a 22.4-volt reading on your VTVM representing 10 Watts of rf, and proceed as above to adjust trim pots R1 through R4. Use a very short coax jumper between the Swattmeter and the dummy load for best results. If your dummy load resistance is off by more than 10% (45-55 Ohms), use Ohm's Law to recalculate the proper voltage for 10 Watts of rf.

The third method that can be used reasonably to calibrate the Swattmeter is to infer the peak line voltage from the dc output of the forward detector, which can be measured with a high impedance dc voltmeter. If you have examined the Swattmeter schematic closely, you will have noticed that the 10k Ohm "Swr Set" controls act as load resistors for the two diodes for all positions of the range selector switch. This loads the diodes on the most linear portion of their response curve, and the calibrating resistors, R1 through R4, plus their respective 100 uA meters, act as simple dc voltmeters measuring the voltages across each 10k control.

No, Virginia, you can't use the Swattmeter meters for self-calibration, but you can calculate the voltage to be expected across the 10k "Swr Set" controls for a given rf power level through the wattmeter. Not wishing to bore you with the math involved, I have shown in Table 2 this relationship for the Swattmeter as constructed.

From Table 2, you will see that 10 Watts of rf produces 0.66 volts at the output of the forward detector (or at the reverse detector if the input/output rf leads are reversed). For 100 Watts, the voltage should be 2.3, for 500 Watts, 5.2 volts, and for 1000 Watts, 7.5 volts. Assuming that you have built a nearly exact copy of the Swattmeter, simply hook up a dc source across both "Swr Set" potentiometers, along with an accurate VTVM or DVM (no rf needed). Set the range selector switch to 500/100 and the dc source to 2.3 V. Adjust R1 and R3 for a 100 Watt reading on both meters. Next, set the range selector to 1000/100 and adjust R2 and R4 for a 100-Watt indication. Run your dc source up to 7.5 volts and check both meters for 1000-Watt indications.

You may have to jockey R1 through R4 a little for compromise readings using the voltages given in Fig. 6. The readings will vary a little because of the load produced by the 100-uA meter movement, but don't worry too much about it. Remember, the Swattmeter is not intended to be a precision instrument—just a handy combination gadget convenient for tuning up and practical as a performance monitor for your station.

Once the calibration is complete, put the back on and install it in a handy location. I installed mine (as you can see from the photos) on a swivel mount, using M-359 angle adapters to keep the coax neat.

Potential Problems

When first constructed, the Swattmeter was erratic on some frequencies—the cause being poor ceramic bypass capacitors. If you experience power peaks, and know it's not caused by your transmitter, replace the capacitors. Another problem experienced was a negative swr indication at very low power levels! This was caused by slightly unmatched diodes which "turned on" at different voltages. If this happens to you, either increase the power level to get each diode turned on or rematch your diodes.

Speaking of diodes, it is possible (although I've never experienced it) that the diodes in any directional wattmeter are likely to produce harmonics of the applied frequency. Change the diodes if you suspect this is happening.

As I said before, Murphy's Law is still in effect, and you could run into some different problems. I have covered all those that I experienced.

Conclusion

My Swattmeter is a comfort when I'm on the air. I can tune up the rig into a dummy load using very little power, switch to whatever antenna I want to use, and load the finals in just a few seconds. It is reassuring to know your finals are putting out just about what they should, and that there is minimum reflected power on the line.

Variations are possible, if you don't like the design or if it doesn't fill your need. You can leave out the range switch and simply calibrate the "Swr Set" control for various power levels. You can eliminate, on the other hand, the swr function and simply have a forward and reflected wattmeter. You even can eliminate both controls, and replace them with fixed-value components for a "one range" Swattmeter. Different power ranges are easy also—just adjust R1 through R4 for wattever (pun intended) full scale power level you desire. And there are still more. . . let me see, now. If I put a 20-dB coupler in there, maybe I can come up with a spare receiver tap. Then there is the possibility of adding another diode and a capacitor and an op amp to read peak power. . . no, on the other hand, I guess the XYL wouldn't stand for it! ■

The Double-Sawbuck QRM Annihilator

—3-IC circuit yields perfect CW

Having been a ham for almost 13 years, I guess you could say that I am set in my ways in some areas. One of these just happens to be CW. I do not work much CW, but when I do, I like to have a strong clear signal to do it with. This little circuit can give you just that.

I like projects that use components that are easily obtainable and not too expensive. All parts here can be obtained from your nearby Radio Shack for less than $10, as well as a copy of their book, *Integrated Circuits, Volume 3, Projects* ($1.50), which helped me to understand the 567 better.

Overall Description

Basically, what this circuit does is take a CW signal from your receiver via the phones jack, and output to you via speaker or headphones a clear, uncluttered CW signal. It will work with very weak signals that are almost impossible to copy. It has an extremely narrow bandwidth so that it can easily separate two very close signals, especially when you are trying to copy the weaker of the two. If someone has a poor-sounding signal (chirp), you will never know it. It will receive RTTY, and you can tape a good signal off the air for practice later. It requires very little power, less than a Watt, so you can use an ac supply—or a small battery will do.

Circuit Description

See Fig. 1 as you read the following description. Audio enters pin 3 of the 567 via coupling capacitor C1. The 567 is a tone decoder which outputs a negative-going signal from 5 volts to 0 volts. The particular frequency that is able to activate the output depends upon a combination of R1 and C3. The center frequency can be determined by the equation: center frequency = 1.1/R1 x C3.

I used a center frequency of 2300 Hz. C2 is called the low-pass filter, and it determines the bandwidth that the 567 will pass at the center frequency. C4 is called the output filter, and it attenuates frequencies that lie outside the desired band of frequencies.

Normally, pin 8 of the 567 is high. When you tune across a CW signal so that

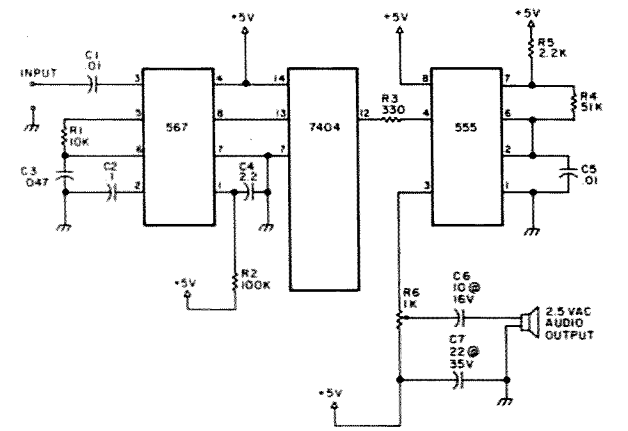

Fig. 1. Schematic diagram of CW circuit. R6 is a Bourns 3339P-1-102 PC board pot. Capacitor values are in microfarads; resistor values are in Ohms. The 555 and 567 are mini-DIP chips.

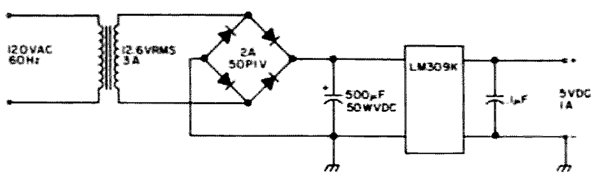

Fig. 2. 5 volts at 1 Amp dc power supply.

it generates the proper tone, pin 8 will go to zero with each dot or dash. So you end up with negative-going CW!

The signal enters the 7404, a hex inverter, at pin 13, and leaves at pin 12 as a positive-going CW signal.

From here, the signal enters the 555 at pin 4.

Data for the 555 can be obtained from *The Linear Control Circuits Data Book*, published by Texas Instruments. The 555 can be set up to run in many different modes. Here it is used to produce a tone every time it sees an input at pin 4. The frequency of this tone is determined by the equation: frequency = 1.44/C5(R5 + 2R4).

So, by changing the values of the components such as R4, you can vary the tone of the output in case you do not like my tone! You could even make R4 a pot, but I did not, to keep the cost low.

The 555 outputs the tone at pin 3, and its volume to your speaker is controlled by R6. Capacitor C7 was used as a filter because I used a 5-volt power supply. If you use a battery, it will not be necessary. And that is it; from the speaker comes uncrowded, clear CW!

Fig. 2 shows a simple 5-volt power supply if you do not already have one.

Summary

You will find that the circuit has a very narrow bandwidth so you have to be exactly at the correct "spot" to get an output. I have enjoyed using this circuit for a couple of months now, and, who knows, it might relight the CW flame in you, now that you do not have to listen to everyone on the band at once! ■

Center Insulator for your Next Antenna

—do it yourself with PVC

Here is a scheme for a center insulator for your dipole or center-fed antenna that does the job beautifully and is inexpensive and easy to make.

The parts are of the ½-inch, heavy-duty, schedule 40 PVC plastic variety, and should be available at your local plumbing supply or large hardware store. Try to obtain parts that are grey in color, as the ultraviolet radiation from the sun is harder on the white. Painting the white PVC with a dark enamel will help here. The strain relief fitting may require a trip to your local electrical supply store. My fitting is a Ralco brand made of cast aluminum which cost 89 cents. This fitting cost less than a pair of coax fittings and is waterproof to boot. Taking the fitting apart will show you how it works much more easily than I can describe, so I won't go into that. Fittings are available that will accept the larger RG-8 size coax also, but I use 58C/U, with which the ¼-inch hole in the rubber grommet works nicely.

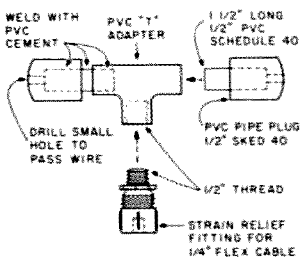

Fig. 1. Details of center insulator.

Run the element wires though their respective end cap holes and tie an overhand knot about 1 inch from the end of each wire. (Hope you use stranded flexible insulated wire, hi.) Pass the coax through the strain relief fitting and out the unglued end of the "T". Strip 2 inches of the jacket off the coax and separate the shield and center conductor. Strip ½ inch of insulation off the dipole ends and make the connection to the coax. Tape up the connections, and then carefully pull the works back into the center of the "T" and complete assembly.

Tighten the compression ring on the strain relief, and you're all set. If desired, before final assembly, the inside of the T-plug caps can be filled with wax, caulking compound, duct seal, etc., for additional protection against moisture through the end holes. You will find the completed project very strong, professional looking, and easily capable of doing its job. It can be tied to a supporting structure with nylon or poly rope, and you can be assured of good insulation and lasting performance. ■

Another Approach to Repeater Control

—uses 7516 chip for low parts count

Over the last couple of years, I have written several articles using the 567 type of IC tone decoder. If you have used these decoders, you probably have discovered that, while they do the job, they have many limitations. They are very sensitive to input level, the decoding bandwidth changes with the input level, and there is bounce or ringing on the output. In order to function well in a complete 16-tone DTMF (touch-tone™) decoding system, the 567s require a lot of special effort, not the least of which is the addition of an agc amplifier.

Our local repeater organization is in the process of upgrading our control system and some of the first things on the list to be replaced were several 567-based DTMF decoders. We reviewed the specifications on several new monolithic tone decoders that have come on the market in the last couple of years. After reviewing the specifications, we decided on the Telenetics decoder which, although expensive (over $100), has several very attractive features, not the least of which is single-supply operation. Telenetics markets a system which consists of two ICs, a tone decoder, and an address selector, either of which is a stand-alone device which can be used without the other. Before proceeding with this article, I would like to acknowledge the help of Jay Hein WB7DQN, who did most of the initial logic layout.

Decoder

A very simplified block diagram of the 7516 decoder is shown in Fig. 1.

To briefly go through the decoder, it has an input audio amplifier which will accept either balanced or unbalanced inputs. The amplifier output feeds low- and high-pass bandsplitting filters which separate the high- and low-group DTMF tone-group ranges. The output of the filters then goes into a limiter. That output then drives an envelope detector and the digit decoder. The envelope detectors provide an input to the decoder portion which tells the decoder if valid dual tones are present. The decoder, through a digital counting scheme, decodes the tones and then provides either a one-of-sixteen logic output or a BCD-coded output, depending upon what the user selects. One thing I didn't mention earlier is a speech detector circuit which prevents false decoding with speech-type waveforms. The device also has several test points brought out which allow checking of device operation. In addition to the test points, a 10-kHz clock signal is brought out. This signal is required by the address selector. The specified operating range of the device is 8 to 28 volts, which adds to the versatility.

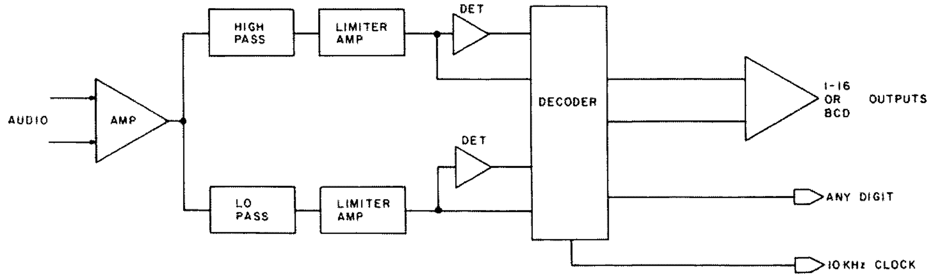

Fig. 1. Simplified block diagram of the Telenetics 7516 tone decoder. We obtained these and the address selectors direct from Telenetics, Inc, 4120 Birch St., Newport Beach CA 92660.

Address Selector

The 7511 address selector does just what its name suggests, i.e., recognizes an address. The length of the address to be recognized is user-selectable to lengths of 2, 3, 4, 7, or 10 digits. The chip requires a 10-kHz clock which can be provided directly from the 7516 tone decoder. This signal is used for internal timing. The selector provides either a positive- or a negative-going logic signal when the correct address is decoded, and the length of this output can be user-selected for 3, 5, or 9 seconds. The ingenious people who designed this circuit also provided for recognizing invalid digits through use of an "ANY DIGIT" output from the decoder or by resetting if too much time is taken in the digit selection. One minor drawback is the input voltage range; the maximum on the address selector is about 17 volts. This

normally won't present a problem.

Control Decoder

Now that I have introduced you to the device we are using, let's take a look at the complete repeater control system we designed around these devices. I divided the system up into blocks which are a little easier to describe. The first of these blocks is the control decoder, the heart of the system. The decoder is shown in Fig. 2.

The connections to the decoder and address selector are very straightforward and come straight from the Telenetics applications notes. The 12 (I didn't use all 16) digit outputs go to pads where they can be jumpered to the digit inputs of the address selector. In addition to these pads, I also ran the digit outputs out to the outside world so that the system can easily be expanded.

There is a 10-kHz clock output from the decoder (mentioned earlier) that is needed by the address selector. I also ran this line to the outside so that additional address selectors could be added at a future date. In order to ignore wrong addresses, the "ANY" line must also be connected. This line provides a pulse for each digit decoded by the decoder.

Pads also have to be provided for the selection of the address length and the address-selector output duration. The selection of 1-of-16 instead of BCD outputs I have shown hardwired, since that was the way our application went.

We used the low-going output of the selector ($\overline{Q}$) to trigger a 555 timer, which in turn puts out an enable signal to the rest of the function decode logic and will hold it for more than the time available from the selector. The # digit is fed through U13A and is used to reset the enable timer if desired. The other input to U13A serves as an inhibit to the control process. If this line is high, it will prevent enabling of the function-selection gates.

Two sections of U13 are cross-connected as a flip-flop and run off the decoded 8 and 9 digits to provide on/off toggling of the selected function.

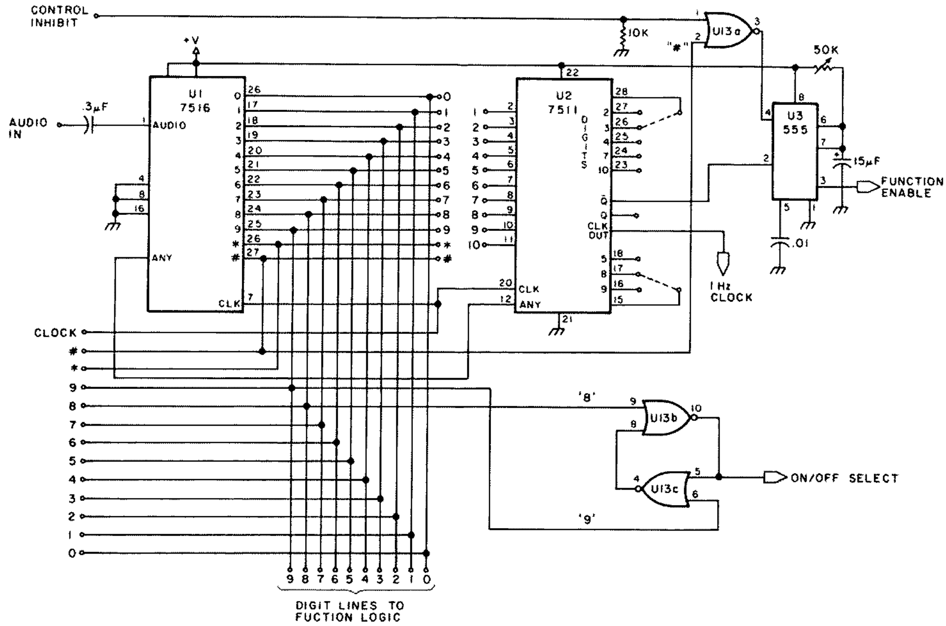

*Fig. 2. Schematic diagram of the decoder section of the complete control system. In this and the following schematics, the arrowheads indicate connections contained on the printed circuit board, while circles indicate those lines which go off the circuit board. The * is available but not used.*

Control Logic

The next section, illustrated in Fig. 3, recognizes that a valid address and control command have been sent and then provides an appropriate latched logic output to the outside world. In the case of the 6 and 7 functions, the logic in our system is hard-wired for timer disable and repeater disable, respectively.

The first digit normally sent would be an 8 or 9 to set the on/off flip-flop condition. The on/off flip-flop output line controls the D inputs to the flip-flops in U6, 7, 8, and 9. Now, if any of the flip-flops are clocked by the action of U4 or U5, their outputs will follow the state of the D input and set or reset the desired function.

In order to illustrate the operation this far, let's

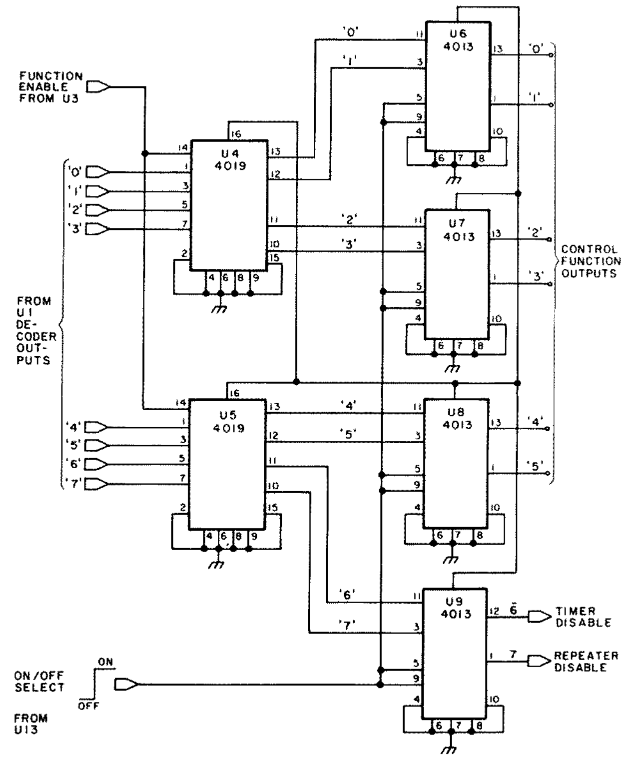

Fig. 3. Schematic diagram of the function decoder section of the control decoder. The control functions 0 through 5 go off the board for whatever auxiliary use may be needed.

assume that the correct address has been selected. U3 will then provide a high on the function enable line for about 5-10 seconds. This high will let the appropriate control-digit pulses through to the rest of the logic. If the next digit to follow the address was, for example, a 0, U4 would pass the high through to U6, where, if pins 5 and 9 were high, it would cause a latched high on the 0 function output. If the 0 had already been high and pins 5 and 9 were low, the output would have been reset to low.

As mentioned earlier, the 6 function is hard-wired for repeater disable and the 7 function is wired for timer disable. I made no attempt to buffer the CMOS outputs because of printed wiring board space limitations and because I thought it would put some restraints on the versatility of the board.

COR/Timer

The last section contains the COR, drop-out delay timer, time-out timer, and beep generator. The schematic for this section is shown in Fig. 4.

The PTT transistor is driven by U14A. One input of U14A is fed with a diode OR gate which allows either the time-out timer or the repeater disable signal from the control circuitry to inhibit the transmitter PTT. The other side of U14A is fed from U14B, which allows PTT operation from an external IDer, a second receiver, or from the internal COR switch.

The primary receiver COR circuit requires a signal keyed to ground when the COR is active. This signal activates timers U15A and U15B. U15A then activates the PTT; the setting of the 50k pot on this IC will determine the amount of time the PTT will stay on after the COR has shut off (drop-out delay). Timer U15B acts in the same manner except that it controls the time out timer. U15B also triggers a beep generator comprised of U16A and B on its falling edge. This provides a short beep when the timer is reset. In order for this function to work properly, the drop-out delay must be longer than the time-out timer time.

A typical setup for this would be to set U15A for about 2 seconds and U15B for about 1 to 1½ seconds. Thus the beep would be heard (and the timer reset) about 1 second before the carrier drops. There is a 50k pot on the beep timer which sets the duration of the beep tone.

One last connection to describe: The line marked COR inhibit, if taken to ground, will prevent the timers of U15 from operating. This effectively precludes PTT operation from the COR. This line was added as an afterthought to add to the possible methods of control. The last but not least section of this functional block is the time-out timer. I neglected to mention that the 7511 address selector also provides an output which is the clock input divided by 10,000, which, for the normal 10-kHz clock input, provides a one Hz output. By simply counting this output, time functions such as time-out can easily be accomplished.

The time-out circuit then simply consists of a chain of presettable counters which count down the 1-Hz clock. The first counter, U10, is hard-wired as a divide-by-10 to give a 10-second output. The second two counters, U11 and U12, are provided with strapping pads to allow programming of the desired time out in increments of 10 seconds. The output of U13D is also fed back to U10, where it stops the counting function, thereby holding the counter in its present state and holding the PTT off. U14 resets the whole timer chain when the COR signal is removed.

Operation

In the last section, I tried to tell you how this thing worked; however, its use is somewhat complicated, so I will try to explain it in some detail. Using the system requires two basic

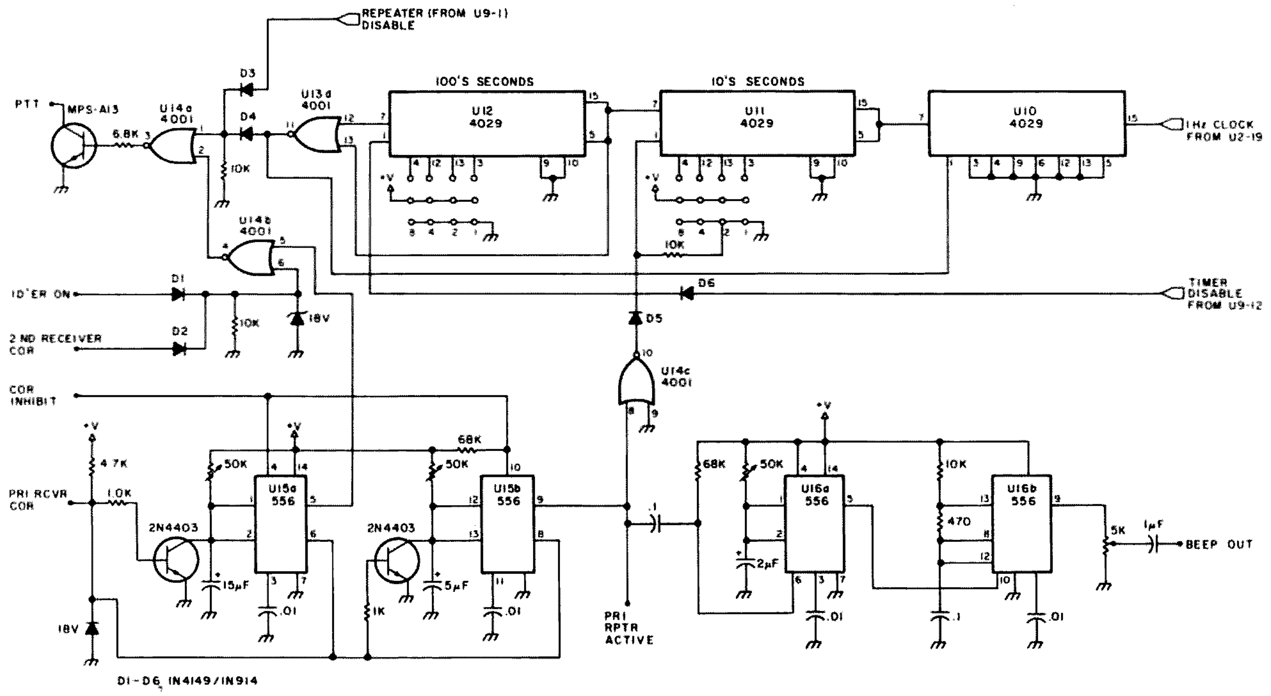

Fig. 4. Schematic diagram of the COR and timer sections of the control system. Note that the repeater disable and timer disable signals come directly from the function decoding logic (Fig. 3).

stages: initial setup and interconnection/adjustment.

Initial setup involves making some decisions and then strapping the options according to your decisions. The first decision is the length of the control address. This can be 2, 3, 4, 7, or 10 digits long. This option is set by installing a jumper between pin 28 of U2 and one of the following pins of U2: 27, 26, 25, 24, or 23.

The second decision, once the length of the address is decided, is what the actual address will be. I think this can best be explained by example. Let's say you selected an address length of three digits (U2, pin 28 to U2, pin 26) and an address of 9-4-2. Pin 2 of U2 is the first digit input, pin 3 the second digit input, and so forth to 10 (max.). Now, you would strap the first digit (pin 2, U2) to the nine digit output of U1, which appears at pin 25. Next, connect U2, pin 3 to the four-digit output (U1-20), and finally U2-4 to U1-18 (the two output). Your decoder system will now respond to an address of 9-4-2. Taking longer than about five seconds between digits or sending a digit out of sequence will cause the selector to reset and reject the address.

The last jumper you have to install on the address selector is the one which determines how long the output will stay active after a valid address is decoded. By jumpering U2, pin 15 to U2, pin 16, 17, or 18, you can select 9, 3, or 5 seconds. The printed circuit board being offered by the ARA* is hard-wired for a three-second time.

One last comment regarding the decoder: It can be jumpered for BCD outputs instead of one-of-sixteen as was done here. To do this, you have to reverse the states of pins 15 and 16. I don't want to go into any more detail since it is a whole different mode of operation.

The selection of time-out requires installation of jumpers also. The jumpers on U11 set increments of 10 seconds and the jumpers of U12 set multiples of 100 seconds. Both are programmed by jumpering the appropriate bit high or low in a BCD code for the digit desired. For example, if you want a three-minute timer, which is 180 seconds, you would program U11 to an 8 and U12 to a 1. To do this, we connect pin 4 of U11 and pin 3 of U12 to +V and then ground pins 12, 13, and 3 of U11 and pins 4, 12, and 13 of U12. This is now all of the jumpers required. The remaining adjustments should be made once the board is installed.

The primary connections to the controller are shown in Table 1.

Each of the function outputs is a latched CMOS-compatible signal which can be used, with the proper buffering, to control a number of various functions.

Conclusion

There we have a complete repeater control system which provides control decode functions, primary repeater control, auxiliary control functions, COR/PTT functions, adjustable squelch tail length, adjustable time-out timer length, and time-out beeper. With some professional assistance, we got the entire circuit on one 4½ x 6 inch plug-in circuit card. The Arizona Repeater Association is going to be marketing the printed circuit boards for the control system along with a compatible CMOS identifier printed circuit board. As of this writing, only prototype boards were completed, so pricing was not available. For pricing and availability, either contact the ARA or me.

One last comment; I almost forgot. Not shown on the schematic but present on our PC boards and highly recommended are .01 uF capacitors on the supply pins of each IC and 18-volt zener diodes on input lines for spike protection. ■

*Arizona Repeater Association, Suite 4000, Valley Center, Phoenix AZ 85073.

Signal	Description
PRI RCVR COR	An input line that is keyed to ground when the primary receiver is active.
COR INHIBIT	A normally open input line. A ground on this line will inhibit operation of the COR/PTT.
PTT	A transistor switch output keyed to ground and capable of about 200 mA. If anything other than a transistor circuit is to be keyed, it should be through a relay.
IDer ON	A high (+V) on this input line from the IDer will keep the PTT keyed while the ID is being sent.
2ND RCVR COR	Provides input capability for a second (link) receiver to operate the PTT. Note that this and ID both bypass the time-out timer.
BEEP OUT	Adjustable audio output signal which can be fed into the transmitter mic input.
AUDIO INPUT	This is the control audio Input which may come from a control line or from another receiver. Not normally fed from repeater receiver.
CONTROL INHIB	This input, normally open, will inhibit the control decoding process if a high is placed on it.

Yes, You <u>Can</u> Build this Synthesizer!

—keep your crystal rig

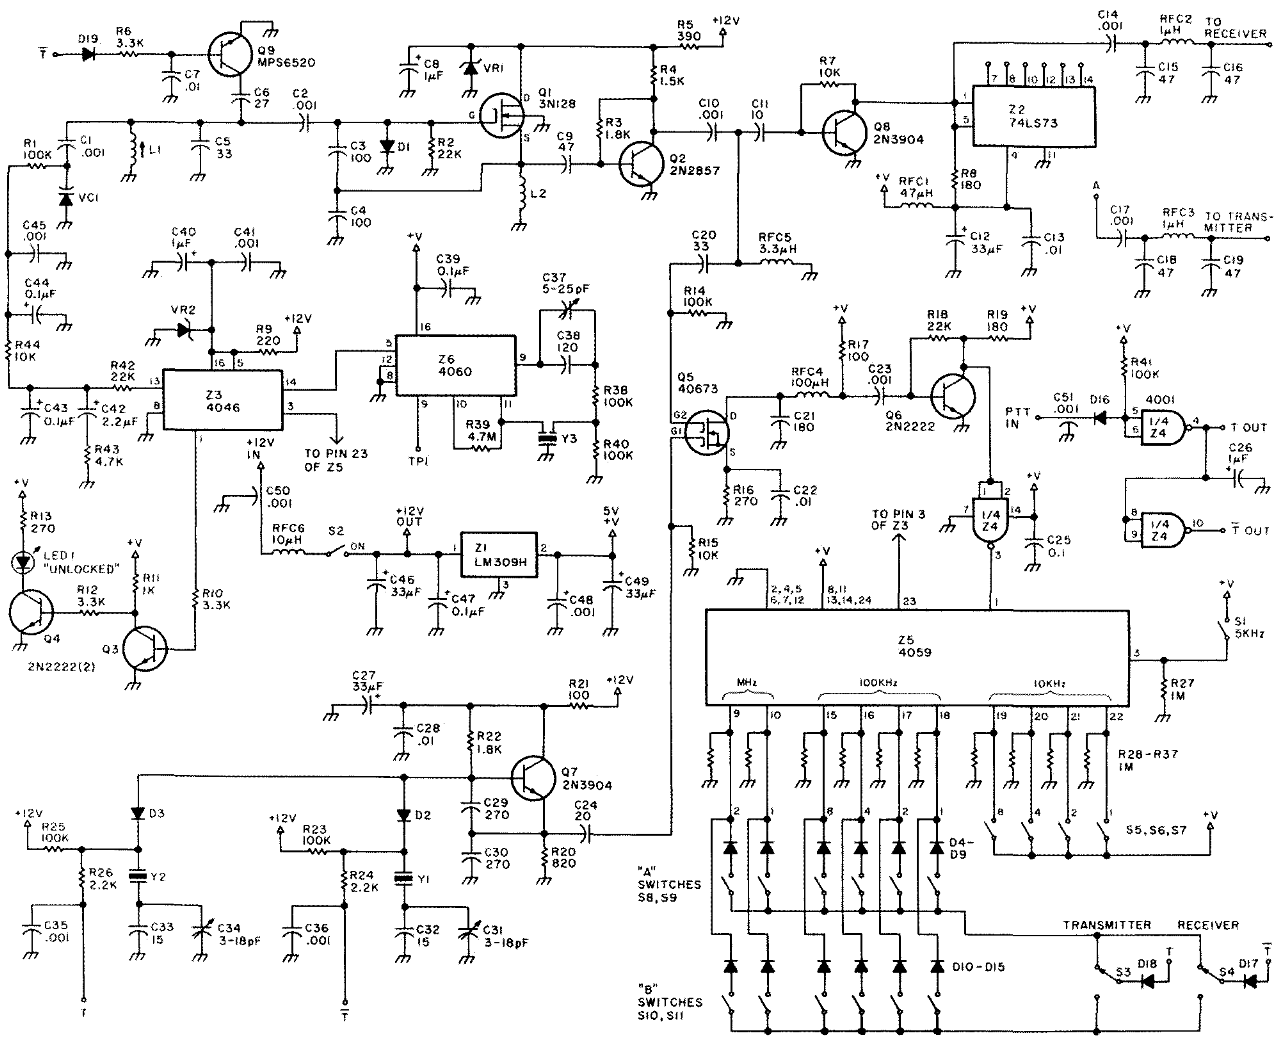

Fig. 1. 2m synthesizer schematic diagram.

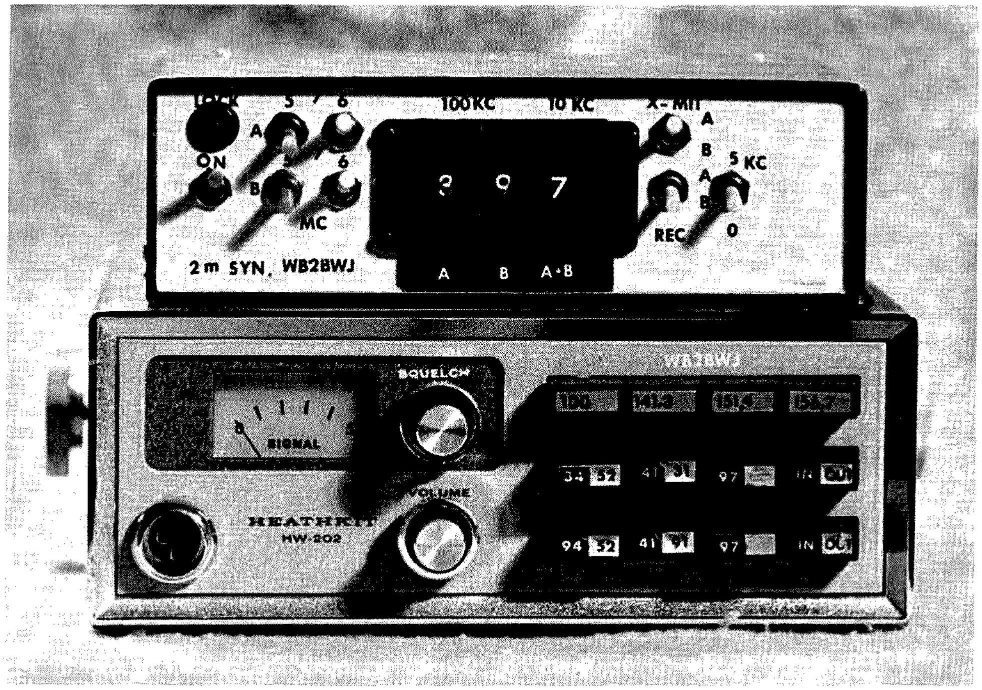

A low-cost, low-power, compact two meter synthesizer can now be built due to recent developments in COSMOS technology. The synthesizer covers 144-148 MHz and can be adapted to almost any rig simply by programming the output divider and using the proper crystals in the beat oscillator. Any repeater offset can be generated, as the receive and transmit frequencies are independently set in 5-kHz steps. The unit uses a total of six integrated circuits and draws about 60 mA at 12 volts. My unit is interfaced with a Heathkit® HW-202.

See Fig. 1. Q1, along with its associated components, forms a vco which has an output in the 22-25-MHz region depending upon what the voltage on VC1 is and if Q9 is turned on or off. Q2 is a buffer amplifier which is connected to one gate of mixer Q5. The other gate of Q5 is connected to Q7, which is the beat oscillator that also oscillates in the 22-25-MHz range depending on which crystal is switched into its base. The output of Q5 contains the sum and difference frequencies of the two signals present at its gates. RFC4 and C21 form a filter which allows the difference frequency to pass on to Q6 which shapes and level-shifts the signal so that it is CMOS compatible.

The first gate of Z4 acts as a buffer to drive Z5, which is a divide-by-N divider. The divider is connected to divide by 800 plus twice the switch settings, and then plus one if the 5-kHz switch is on. These switches are labeled as to what decade of the frequency they determine. The output of the divider goes to the input of Z3, which is a phase comparator. The other input of Z3 goes to Z6, an oscillator /binary divider, whose output is 833.333 Hz. This is the reference frequency. The output of Z3 is connected to a low-pass filter whose output goes to varactor VC1.

Let us now trace a complete cycle of the loop (see Fig. 2). Suppose we want to transmit on 146.940 MHz, and we set the switches as such. Our divider divides by 800 + 2(294) = 1388. Suppose that the vco is free-running at 24.00 MHz. This mixes with the 23.3333-MHz transmit crystal to give an output of .6667 MHz. This is divided by 1388 to give 480.3 Hz. This is compared to the 833.333-Hz reference, and the 4046 raises the voltage to VC1 to increase the frequency of the vco. When the vco has an output of 146.940 MHz/6 which is 24.490 MHz, the loop will

For 24-MHz crystals, connect point A (C17) to pins 1 and 5.
For 12-MHz crystals, connect pin 13 to A.
For 8-MHz crystals, connect pin 8 to pin 14, pin 7 to 12, pin 10 to 13, and pin 14 to A.
For 6-MHz crystals, connect pins 7, 10, and 12, all tied together, and pin 8 to A.

Table 1. Programming chart for Z2. All of these connections are made directly to the socket pads of Z2.

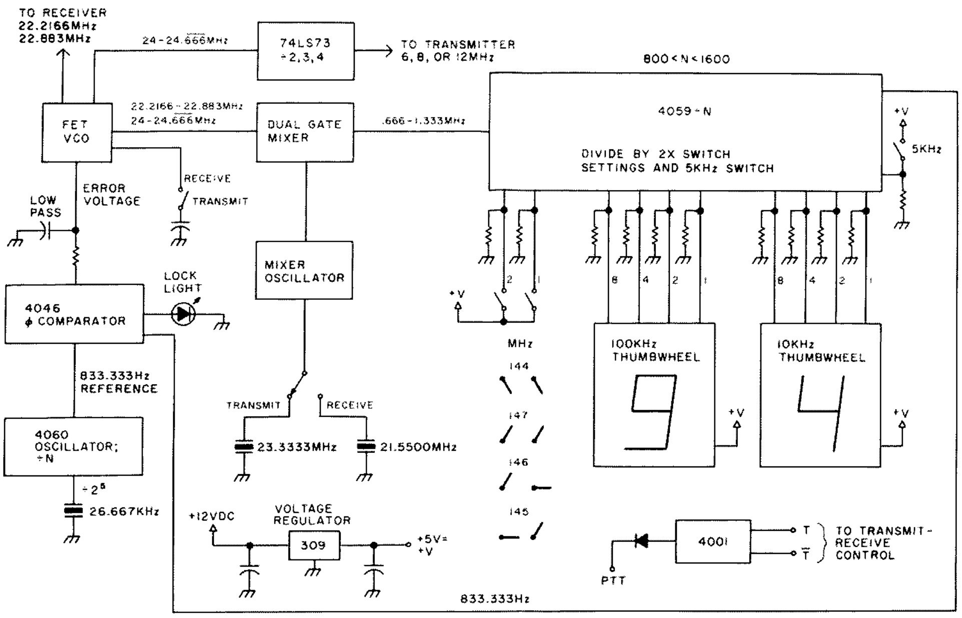

Fig. 2. 2m synthesizer block diagram.

lock since (24.490 − 23.333)/1388 equals 833.333 Hz.

The 4046 will adjust its output voltage so that the two inputs are identical in phase and frequency. Q3, Q4, LED 1, and associated components form an indicator that lights when the synthesizer is unlocked. This indication

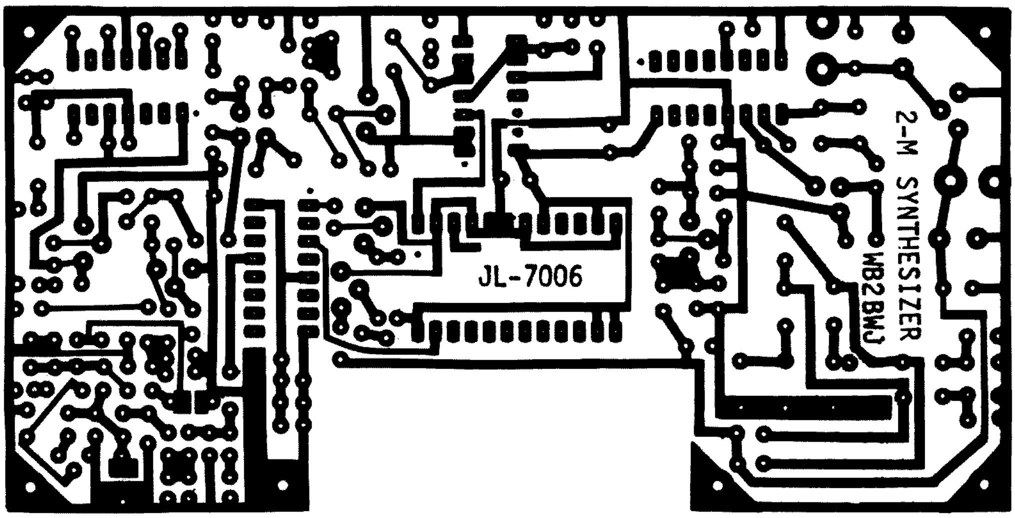

Fig. 3. PC board layout.

is useful when initially tuning the synthesizer, and warns the operator not to transmit if the loop becomes unlocked due to component failure, etc.

The second and third gates of Z4 generate two signals: T and $\overline{T}$ (pronounced not T). T is high in transmit and low in receive, and $\overline{T}$ is its complement. These signals switch between Y1 and Y2, select which set of frequency switches is connected to the 4059, and turn Q9 on and off, which places C6 in parallel with the vco tank to lower its frequency range in the receive mode. Q8 is a buffer stage which isolates the vco from the output circuitry.

Before the signal from Q8 goes to the receiver, it is passed through the low-pass filter composed of C14, C15, C16, and RFC2. This passes the 24-MHz rf, but keeps the VHF rf from the transceiver from getting into the synthesizer. Q8 is also connected to Z2, which is a quad flip-flop. By connecting the pins of Z2, as shown in the programming chart, Table 1, the chip can divide the 24-MHz signal by 2, 3, or 4, giving a 12-, 8-, or 6-MHz output. The transmitter's signal also goes through a low-pass filter.

Z1 is a five-volt regulator which supplies power to most of the circuit. Some parts of the circuit require 12 volts, and this is obtained at C46. In the HW-202, I take the supply voltage off the 11-volt regulated line within the radio.

Parts layout is fairly critical, and it is recommended that the PC board layout shown in Figs. 3 and 4 be used. Keep all leads as short as possible and mount Y3 and Z1 flush to the board. The use of IC sockets is encouraged. Resistors R28-37 and diodes D4-15, D17, and D18 are not mounted on the board but directly on the switches concerned. C50 and C51 are .001-uF feedthroughs mounted directly to the metal cabinet enclosing the synthesizer. RFC6 is not mounted on the board but is connected directly to feedthrough capacitor C50. RCA-type jacks are used for the receiver and transmitter output connectors. RG-174/U, 50-Ohm miniature coax is used to connect the receiver and transmitter output from the boards to their respective low-pass filters and jacks. The low-pass filters are assembled around the jacks. There are several jumpers that are connected to the bottom of the board (Table 2). They are noted on the parts placement diagram as J1, J2, etc. For example, a jumper must be connected from one point labeled J1 to another point labeled J1. Some jumpers go to more than one place. For example, there is a J4a, b, and c. This means that J4a goes to J4b and J4b goes to J4c. All jumpers are RG-174/U coax, and provision is made at each point for the shield to be soldered to

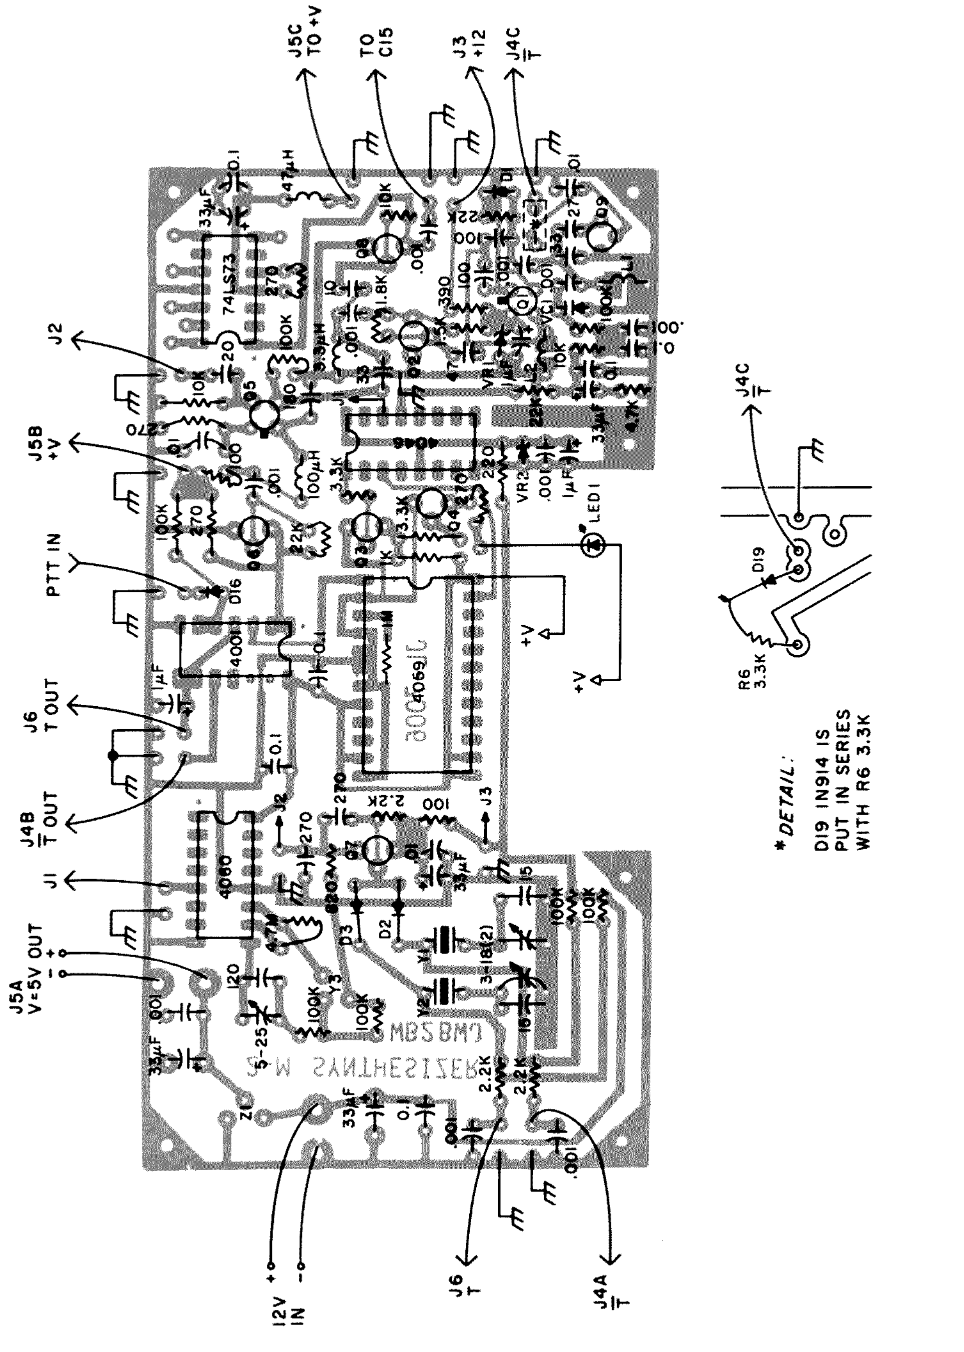

Fig. 4. Component placement.

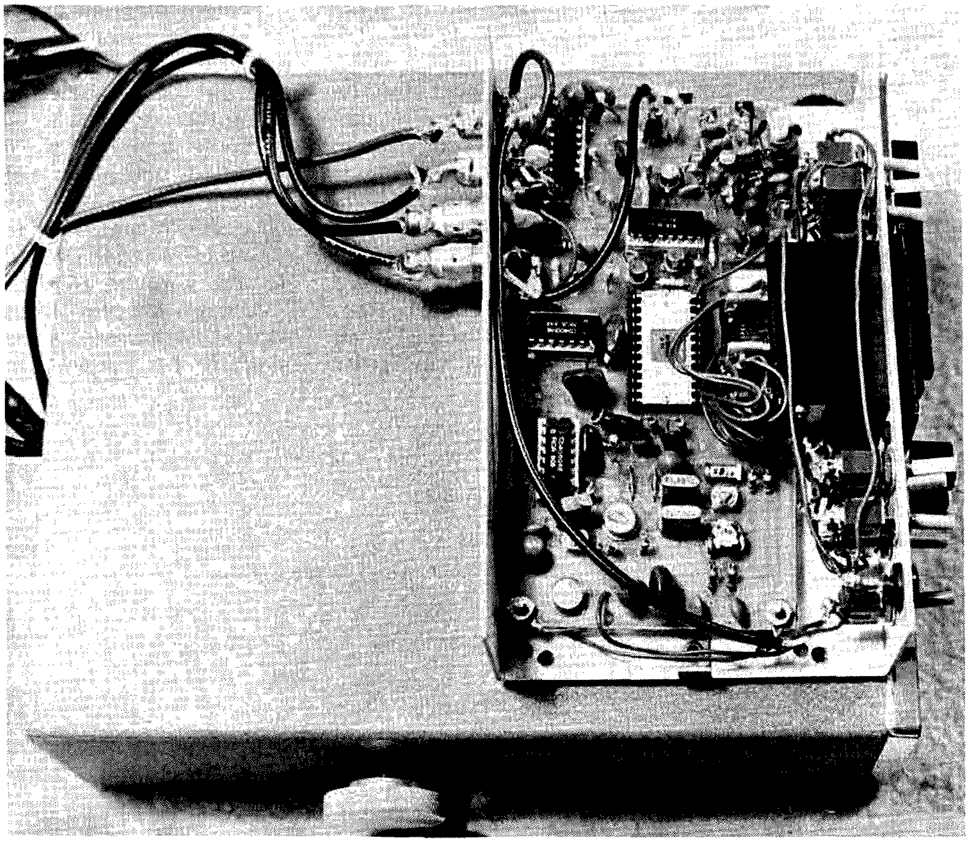

ground. Table 3 shows the cable lengths.

The switching arrangement I used (Fig. 5) was designed to keep the number of thumbwheel switches to a minimum. The arrangement consists of two sets of switches, one labeled A and the other B. S8 and S9 are SPST switches that comprise the MHz selection for the A set. Placing both switches down (turning them off) sets the MHz to 144, S9 up (S8 down) is 145, S8 up (S9 down) is 146, and both up is 147. S10 and S11 work in a similar fashion for the B set. S5 is a thumbwheel switch that selects the 100-kHz step for A; S6 does this for B. S7 is another thumbwheel that sets the 10-kHz step for both A and B. S1 selects whether or not 5-kHz step is used. S3 and S4 select whether or not the A or B setting will be used for transmit or receive.

As an example, if we want to go on 146.34/146.94 with A selecting the transmit frequency and B selecting the receive frequency, we set S8 and S10 to on, S5 to 3, S6 to 9, S7 to 4, S3 to A, and S4 to B. To go on simplex on 146.34, say, to monitor the input, we set S4 to A. To go simplex on 146.94, we set S3 and S4 to B. To go on reverse 146.94/146.34, we set S3 to B and S4 to A. With this method of switching, most common repeater pairings can be obtained. If a more sophisticated system is desired, an automatic offset[1] could be built in, or a keyboard-type entry system[2] could be used. The important thing to note is that the synthesizer only requires the BCD code of the desired frequency—no look-up table is needed.

Mount all of the parts on the board in the following order: sockets, resistors, capacitors, chokes, transistors and diodes, crystals, and jumpers. Before inserting the IC chips, apply 12 volts to the unit and check for the proper supply voltages at the IC sockets. After turning the supply off, insert all of the IC chips. Turn the unit on again and the unlocked light should come on. The first signal to check on the unit is pin 14 of Z3. There should be a 5-volt peak-to-peak square wave at a frequency of 833.333 Hz. With an accurate frequency counter, preferably set to measure the period, adjust C37 until the frequency, or period, is as stated. This adjustment could also be made by looking at pin 9 of Z6 and setting C37 for a frequency here of 26.6666 kHz. Connect the positive lead of a VTVM or FET VOM to the lead of R1 farthest from VC1. The voltage here probably will be either near zero volts or near 10 volts, either of which represents an unlocked condition. With the synthesizer in the receive mode, set the frequency select switches to 147.995 MHz and adjust the tuning slug on L1 until the voltage reads approximately four volts. The unlocked light should now be extinguished. Change the frequency select switches to 144.000 MHz and check to see if the light is still extinguished. Simulate the transmit mode by grounding the PTT line on the synthesizer and check to see that the synthesizer locks over the same frequency range in transmit. The voltages at R1 should be within 0.5 volts of one another for the same frequency on transmit and receive.

Trim L1 until the tuning range is correct. Any con-

Photo A.

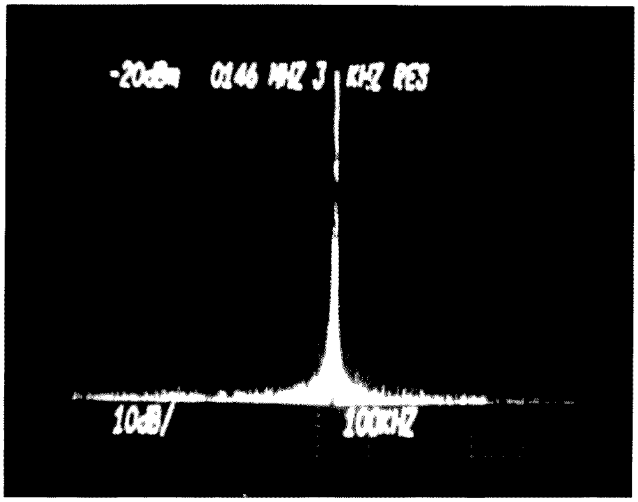

Photo B.

stant flickering of the unlocked light indicates an unstable condition, and the transceiver should be keyed only if the light is fully extinguished. A brief flash of the light when setting the frequency select switches, or when keying the transceiver, is just an indication that the synthesizer has become unlocked momentarily while changing frequency.

With the PTT line open (receive mode), connect a frequency counter to the receiver output jack and set the frequency select switches to 146.000 MHz. Adjust C34 until the counter reads 22.5500 MHz. Ground the PTT line (transmit mode) and adjust C31 until the counter reads 24.3333 MHz. It should be noted that the reading of 22.5500 MHz in the receive mode assumes that Y2 is 21.5500 MHz, which is the proper crystal for a 10.7-MHz i-f. For any other i-f, the counter should read (24.3333 − i-f/6). This completes the calibration of the synthesizer.

The unit should be built in a metal box with a cover that makes good electrical contact all around its perimeter. This prevents rf from getting into the synthesizer from the transceiver. Connecting leads to the transceiver should be made with RG-174/U. The first step in interfacing the synthesizer to the transceiver is to select Y2. Its value depends on the i-f frequency of your transceiver. For a radio with a 10.7-MHz i-f and receive crystals in the 45-MHz region, Y2 will be (23.3333 − 10.7/6) = 21.5500 MHz. For other i-fs, (23.3333 − i-f/6) will give the value for Y2. Even though the transceiver takes 45-MHz crystals and 22-23 MHz comes from the synthesizer, the receiver's oscillator and multiplication circuits do the proper multiplication. Receivers using 15- or 22-MHz crystals will also work with this scheme.

Connect the receiver output coax to the transceiver at an unused receiver crystal socket. Use a .001-uF capacitor to couple into the socket (Fig. 6).

The transmitter output coax from the synthesizer also goes to an unused crystal socket, but a 100-Ohm resistor and a .001-uF capacitor are connected as shown in Fig. 7. The resistor assures smooth operation of Z2. A ferrite bead is placed as shown to act as a choke which keeps the VHF rf from entering the synthesizer.

The PTT input line should go to a line in the transceiver that is open or has at least +5 volts on it during receive and is grounded during transmit. This line will most probably be the PTT line from the microphone to the relay. The +12-volt input line can go to the same place from which the transceiver gets power, but if it is at all possible, connect it to some source of regulated and hash-filtered power within the rig. A ferrite bead should be placed at the ends of the coax on both the PTT and +12-volt connections. See Fig. 8.

The most difficult part of interfacing the synthesizer to a particular transceiver is keeping stray rf from the transceiver from getting into the synthesizer. This problem will be noticed when your audio is reported as sounding bassy or distorted. A very severe case of rf leakage will cause the unlocked light to glow on transmit. A less severe case will cause the aforementioned bassy audio.

Cable	Length (inches)
J1	3½
J2	3¼
J3	4¼
J4ab	3½
J4bc	4½
J5ab	3½
J5bc	2½
J6	3½

Table 3. Cable lengths (RG-174/U).

If you have this problem, listen to yourself on a nearby receiver. Disconnect the receiver's coax at the synthesizer while transmitting, to see if the audio clears up. If it does, then this is the path of leakage. Try more ferrite beads or an additional low-pass filter in series with the other one. To check if the rf is leaking through the power supply line, temporarily run the synthesizer off a 12-volt battery and see if the audio clears up. If it does, try more ferrite beads or a larger value for RFC6. To check if the rf is leaking through the PTT line, disconnect it from the synthesizer and simply short the PTT input to ground. If the audio clears up, try more ferrite beads or another bypass capacitor. If none of these remedies seems to cure the problem, then the transmit

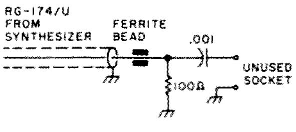

Fig. 7.

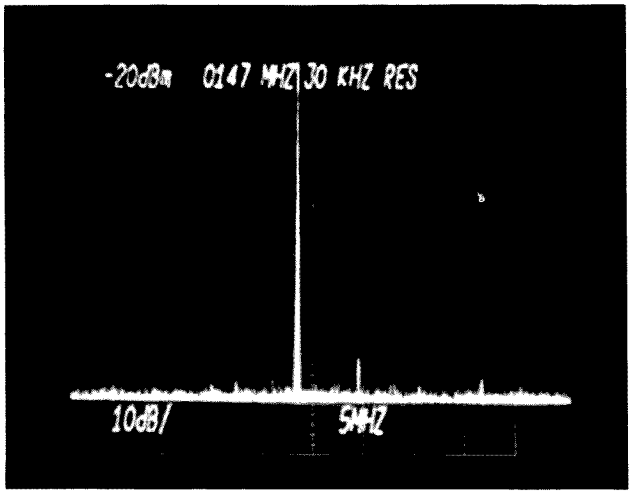

Photo C.

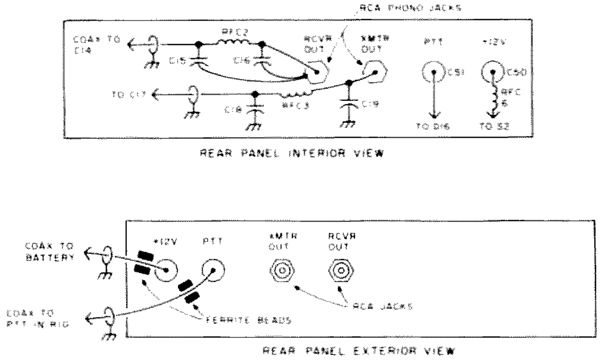

Fig. 8. Rear panel connections.

coax is probably the path of coupling, and additional ferrite beads or another low-pass filter probably will fix it.

Photo A is a spectrum analyzer photograph of the 6-MHz output of the synthesizer being sent to my transmitter. The analyzer is set for a 30-Hz resolution, 500 Hz per division, and a 10-Hz video filter in place. The vertical is calibrated at 10 dB per division. The signal is very clean; there is no sign of the 833.333-Hz reference sidebands, and the noise is 60 dB down. Photo B is the output of my transceiver with the synthesizer set at 146.000 MHz. The analyzer is set for 3-kHz resolution, 100 kHz per division, and 10 dB per division vertically. There are no close-in spurs within 60 dB. Photo C is also the output of my transceiver, but the resolution is 30 kHz, and every division now represents 5 MHz. The strongest spur is at about 154 MHz, but it is 60 dB down, complying fully with the latest FCC regulations for spurious output.

In conclusion, this synthesizer is performing very well on my HW-202. It is a versatile design and it leaves room for many additions that people may want to incorporate. ■

Arlington VA 22204

The use of OSCAR to transmit human electrocardiograms (ECG—or EKG, after the German spelling), and the article in the February, 1978, issue of *73 Magazine* ("Inexpensive EKG Encoder" by WA3AJR), indicate interest in the transmission of analog data. The techniques needed to transmit the human ECG are also useful for transmitting almost any form of analog data signal in which the repetition rate is low and all frequency components fall into the "under 500 Hz" range. In this article, we will examine such circuits from the viewpoint of the human ECG and certain other physiological signals, but the information can be applied to other problems as well.

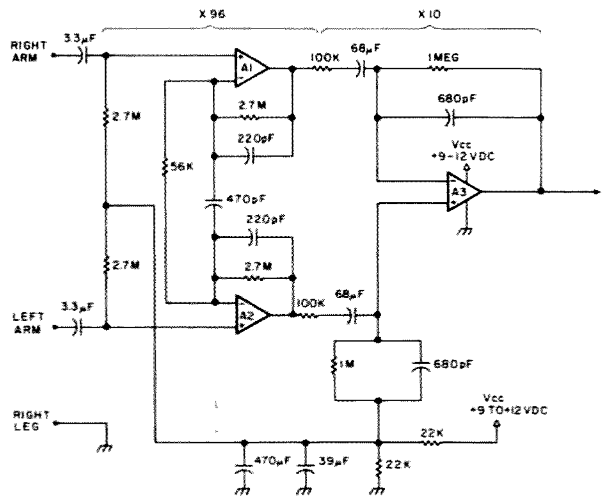

Fig. 1. Typical ECG preamplifier.

The ECG Preamplifier

The peak amplitudes in the ECG waveform are on the order of 1 or 2 millivolts, and significant frequency components exist in the 0.05- to 100-Hertz range. Electronic amplifiers used in professional diagnostic ECG equipment will have this AHA-recommended frequency response, while equipment used exclusively for monitoring usually has a frequency response of 0.05 to 40 or 50 Hertz (depending upon manufacturer).

ECG preamplifiers usually are differential types so that their inherent rejection of common mode signals can be used to eliminate 60-Hertz interference.

Additionally, ECG preamps must be capacitor-coupled to prevent drift due to changes in the *electrode-offset potential* that exists between the electrode and the patient's skin. The electrolytic skin surface reacts with the metallic electrode to form a battery that produces upwards of a volt or more.

Fig. 1 shows the circuit for an ECG preamplifier used in a battery-operated radio telemetry transmitter. This circuit operates from a single 9- to 12-volt dc power source, although, in most non-portable applications, it could easily be redesigned to take advantage of the operational amplifier's bipolar power supply terminals.

The circuit in Fig. 1 is basically an ac-coupled version of the classic instrumentation amplifer, and has a voltage gain of approximately 1000 (see "Op-Amp Encyclopedia"

by K4IPV, *73 Magazine,* February, 1978).

Under specific sets of circumstances, ac mains-powered equipment can be hazardous to connect to some patients, so modern ECG preamplifiers use isolated designs. In most cases, the output of a preamplifier such as in Fig. 1 will be used to amplitude-modulate an oscillator operating in the 30- to 100-kHz range (see Fig. 2). The preamplifier will be on an isolated portion of the printed circuit board, along with the amplitude-modulator and a floating rectifier-filter that creates a dc power supply from the 50-kHz signal. Alternatively, some use separate dc-to-dc converters that do essentially the same thing from a separate oscillator.

The situations that create a hazardous environment for patients do not ordinarily exist outside of the hospital/medical environment, but experimenters and science-fairists who might want to use these techniques are advised *not* to connect people to *any* mains-powered equipment. The use of battery power provides the same isolation as used in professional equipment, but only if the entire apparatus is battery operated.

Transmission Encoders

Some portable units do not encode the ECG waveform at all before transmission, and are called direct-FM telemetry systems. In this type of transmitter, the output of a preamplifier such as in Fig. 1 is applied directly to a varactor-modulated crystal oscillator. In one popular brand, the oscillator operates at 12 to 14 MHz and is multiplied into the 174- to 215-MHz region with the final deviation being 75 kHz or so.

Other models first encode the ECG waveform in the form of a frequency-modulated audio carrier that can be transmitted over a wire or radio communications channel. This method is called FM/FM telemetry. The encoder consists of a voltage-to-frequency converter, or voltage-controlled oscillator (vco), that uses the ECG signal as its control or input voltage. The output of the vco is then applied to an ordinary FM transmitter.

Fig. 3(a) shows a circuit for an ECG encoder that was originally designed at the National Institutes of Health (NIH)[1] in Bethesda MD, for use in telephone call-in cardiac pacemaker-surveillance systems.[2] The circuit was built into the case of a modem (modulator/demodulator used in computer systems), and was issued to patients. The box had a pair of telephone earpiece cups so that the tone could be transmitted down the line. The patient would phone in to the pacemaker clinic once a week, where an analog recording of the waveform was made, and certain computer measurements were taken. These were reviewed later by a cardiologist (an M.D.), who would decide whether or not to ask the patient to come in for a closer examination.

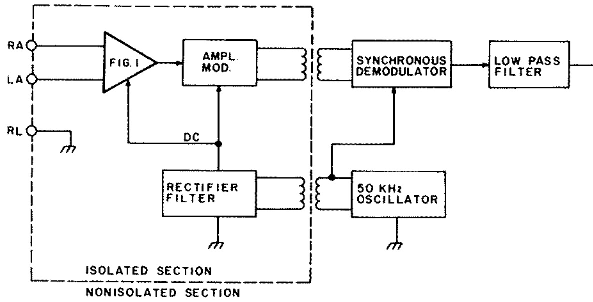

Fig. 2. Block diagram of an isolated ECG preamplifier.

The encoder in Fig. 3(a) uses four 741-family-operational amplifiers and a Motorola MC4024P vco chip that drives a loudspeaker in the modem box. Note that this device is filtered too heavily to provide diagnostic quality ECG recordings, but is sufficient for the limited purpose intended. For those who wish to use the circuit for a wider frequency-response system, some modification of the low- and high-pass filter sections is in order.

Gain is provided by amplifier A1, while A2 serves as the high- and low-pass filter section. The frequency response was limited intentionally so that interfering signals from the patient's skeletal muscles did not obscure the ECG waveform—a necessity because of the less-than-optimum situations in which recordings were attempted. The amplifier input lines were connected to a pair of 1.5-inch metal disk electrodes on the top surface of the modem box. This is not the best possible configuration, but is convenient for the home patient.

The 60-Hertz power mains will cause a tremendous interference signal to be present in nondifferential amplifiers and in those differential amplifiers in which the input balance cannot be maintained. To overcome this, a 60-Hz notch filter, A3 plus the cir-

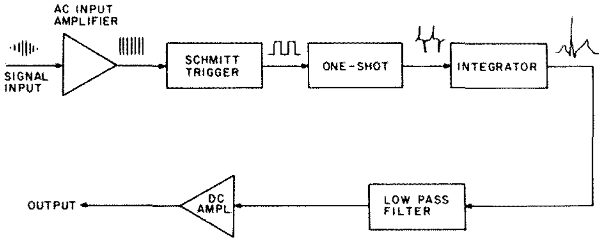

Fig. 4. Block diagram of a pulse-counting FM detector.

cuit in Fig. 3(b) is provided. A claim of 50-dB suppression is made, but we could verify only 18-23 dB.

Amplifier A4 serves as a level shifter between the ECG preamplifier and the MC4024P vco input. The output of the vco is fed to a loudspeaker for acoustical coupling to a telephone. Note that a series resistor is used between the speaker and the vco. This component is needed because the TTL output of the vco will be loaded too much by the low impedance typical of speakers.

The output of the vco in Fig. 3(a) is too high for most radio transmitter audio input stages, and the waveform consists of a chain of square waves. To overcome this problem, an attenuator/low-pass filter is needed between the vco output and the radio transmitter input connector.

Decoders

Neither the circuit of Fig. 3(a) nor the circuit presented in the February, 1978, issue of *73* is useful by itself, except to show that your heart can control the whistle of the modulation in the loudspeaker! Unless a decoder (i.e., FM demodulator) is provided, all these circuits can do is whistle at you in step with the ECG waveform!

The encoded signal is an audio-range (1 to 5 kHz) carrier that is frequency-modulated by the ECG waveform. Any phase-sensitive detection scheme could conceivably work, but two types are most commonly employed: phase-locked loops, and pulse-counting (also called digital) FM demodulators.

A number of technical papers have been written that show the use of low-cost PLL chips for ECG telemetry decoding, but, in my experience, these circuits have not been altogether satisfactory. It seems that many of the low-cost PLL chips do not recover rapidly enough following the ECG R-wave (the spike-like feature). This results in distortion of the waveform in an area that is of particular interest to the physician. Such circuits should, however, prove interesting to the hobbyist who can tolerate some distortion.

It is a little easier to use the pulse-counting detector of Fig. 4. The signal received from the radio loudspeaker or telephone line will probably be weak and noisy, so the first stage will be an amplifier and bandpass filter stage. It should have a bandwidth that is not much greater than the signal's frequency swing, i.e., 2x deviation. In most encoders, the deviation is 25 to 75 percent of the unmodulated carrier frequency.

The amplified audio-FM carrier is then squared in a Schmitt trigger circuit or other form of circuit that will produce output square waves from irregular input signals. The output of the Schmitt trigger is then differentiated to form spike pulses that are suitable for triggering a monostable multivibrator (one-shot).

The actual detector consists of the one-shot and an integrator stage. This arrangement is common not only in telemetry applications, but also in many industrial and scientific instruments, including FM-carrier tape recorders that record low frequency analog data on ordinary audio tape. This circuit produces a dc level that is proportional to the frequency or pulse-repetition rate of the input signal.

The one-shot produces an output pulse for each trigger pulse received at its input. The one-shot output pulses differ from the input pulses, however, in that they have a constant amplitude and duration (period). Only their repetition rate varies with the input frequency. As a result, the output of the integrator, which is a time-averaging circuit, is a dc level proportional only to frequency. Note that at least one high-quality hi-fi FM tuner uses this technique at 10.7 MHz to demodulate the FM i-f signal. The integrator is a form of low-pass filter, so the circuit is inherently low-noise.

A practical example of this type of detector is shown in Fig. 5(a). Note that this is not a clinically acceptable circuit, but it is able to produce results that are good enough for educational or experimental applications. Most serious experimenters wishing to transmit low-frequency human or animal physiological signals by radio or wire, or to store them on an audio tape, will be successful with this circuit.

An LM311 voltage comparator is the input signal conditioner. This circuit is connected as a zero-crossing detector and requires at least 200 mV of signal to operate reliably. Lower signals can be accommodated if IC1 is preceded with an operational amplifier gain stage.

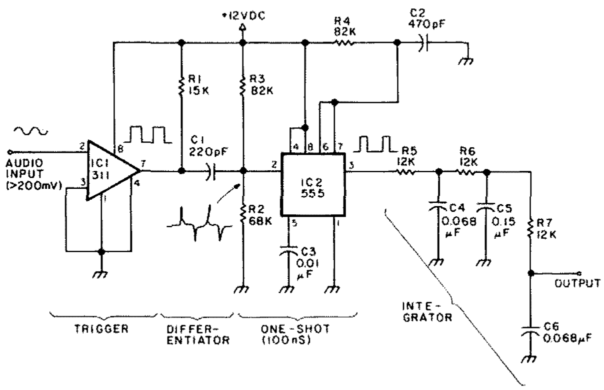

Fig. 5(a). Practical hobbyist decoder circuit.

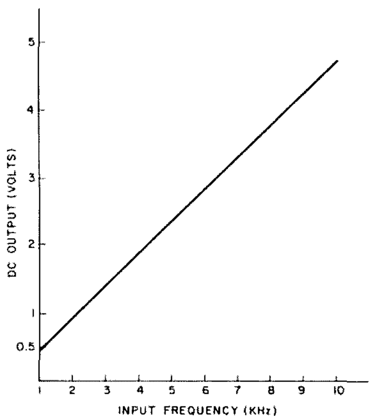

Fig. 5(b). Output voltage versus input frequency.

The square waves at the output of the LM311 are differentiated by C1-R2 to form spike pulses that will trigger the 555 one-shot stage (IC2). The 555 output pulses have a constant amplitude and duration, but their repetition rate varies with the input frequency.

The 555 pulses are integrated in a three-stage RC integrator. The output is taken across capacitor C6, and is a frequency-dependent dc potential. The graph showing input frequency versus dc voltage is shown in Fig. 5(b).

Does it work? I built a modulator using the A4/IC1 portion of Fig. 3(a) and used a function generator to drive its input. A triangle waveform of 2 Hz was selected because it approximates the frequency components of the ECG waveform. The output of the modulator was attenuated and then applied to the input of the circuit in Fig. 5(a). Fig. 5(c) shows the original input waveform from the function generator (upper trace) and the dc output of the decoder (lower trace). Note that the demodulated version shows some, but not much, loss of high frequencies in the waveform.

The vertical gain of the oscilloscope used was adjusted to show more clearly the two waveforms. The amplitude of the upper trace was several volts p-p, while that of the lower was approximately 80 mV p-p. An operational amplifier following the integrator would build this level up to whatever level is required.

Accessories

A qrs-beeper can be used by using the R-wave to trigger an audio oscillator. this is the "beep-beep" used to good effect in doctor TV shows. A popular method is to use the R-wave to fire a one-shot that drives one input of a NAND gate. The other input of the NAND gate is driven by a 1-kHz (or so) audio oscillator.

Alternatively, the output of the one-shot that is triggered by the R-wave can be connected to an LED to form a qrs-flasher. These circuits are shown in Fig. 6. In both cases, the noninverting input of the comparator might either be grounded, as in Fig. 5(a), or connected to a dc level that prevents the comparator from firing on noise impulses or, in most cases, the ECG T-wave.

The circuit of Fig. 5(a) is also useful to make a cardiotachometer (jargon for heart-rate meter) if the time constants are changed. The ECG waveform has a fundamental frequency of approximately 0.5 to 2 Hz, so it will not work properly with the 2-kHz values used when the decoder in Fig. 5(a) is used, but the same principle is used in the tachometer. (The same principle has been published many times as an auto tachometer, incidentally, again with suitable component value changes).

In the case of a cardiotach, the one-shot duration should be 25 to 50 ms, and the values of the integrator capacitors and resistors will probably have to be raised. The dc output meter can be calibrated in beats-per-minute. If you do not have a 1-Hz range function generator to calibrate this circuit, then use TTL or CMOS counter/dividers *a la* crystal calibrator circuits to divide the 60-Hz line from a 5-V ac filament transformer (*not* direct from the 115 V ac line!) down to 0.5, 1, and 2 Hz for calibration purposes. ■

The MICROSIZER: Computerized Frequency Control

—a synthesized vfo replacement for most HF rigs

The use of microcomputers in the operation of amateur radio stations has increased rapidly in the past year. Applications have ranged from simple Morse keyboards to complex antenna-tracking systems. One use that has been neglected is that of controlling the frequency of a transceiver with a microcomputer. Microcomputer frequency control is extremely useful and flexible, but has not been explored because of the incompatibility of analog vfos in transceivers with the digital output of the microcomputer. Now, however, it is possible to combine a handful of inexpensive digital ICs with a few discrete components on a single printed circuit board to form a 5.0-5.5-MHz frequency synthesizer. This unit can serve as a solid-state replacement for the mechanically-tuned vfos used in nearly every popular amateur HF transceiver. Because thumbwheel switches do not meet the amateur's requirements for casually scanning the bands, a convenient method of "tuning" the synthesizer is needed. The marriage between the computer and the radio was inevitable. This article presents a practical approach to building an HF synthesizer for your transceiver, plus some simple software to enable a 6800-based microcomputer to control it.

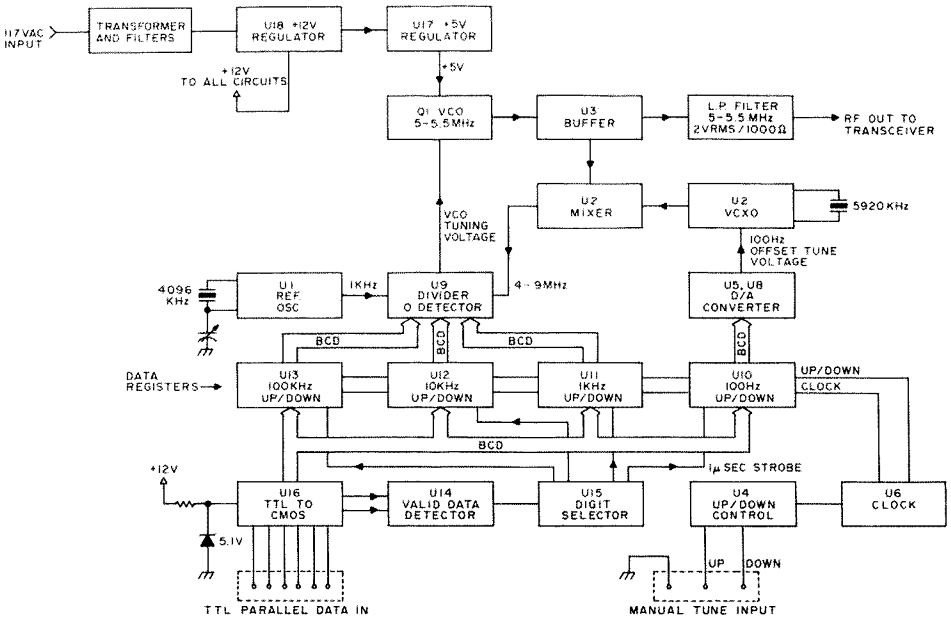

Fig. 1. Block diagram of the MICROSIZER. All parallel data bits are normally high between data words for at least 1 μs. Valid data should be held for a minimum of 4 μs. All digit values are BCD. Digit selector: 100 Hz = 00; 1 kHz = 10; 10 kHz = 01; 100 kHz = 11.

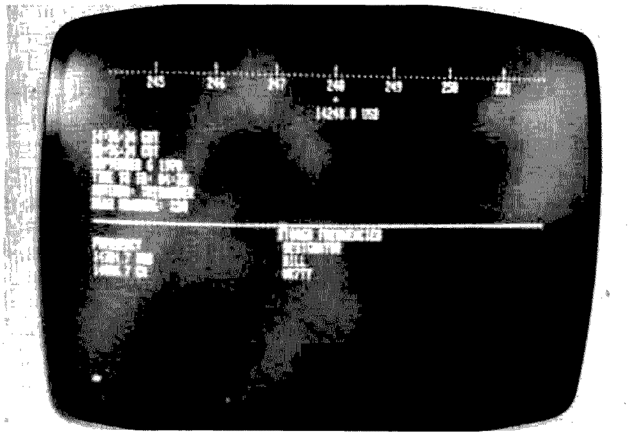
The Hardware

The MICROSIZER, as it is affectionately called, is a solid-state, digitally-synthesized remote vfo that will operate with virtually any HF transceiver. It tunes the popular 5.0-5.5 MHz vfo range in precise 100-Hz increments and can

MICROSIZER in operation at WA0QJI.



Simulated "dial" display.

be controlled by an 8-bit parallel interface port from any microcomputer. The frequency stability and signal purity are excellent, exceeding that of most analog vfos. When controlled by a computer, a CRT terminal is used for entering and displaying the operating frequency. Alternately, the MICROSIZER can be used by non-computer-equipped amateurs as a stand-alone remote vfo with fast or slow up/down tuning controlled by the station's keyer paddle. When operating without a computer, a digital readout in the transceiver is used to indicate the operating frequency. A dual paddle is preferred, offering a slow tuning rate of 500 Hz per second if either the up or down paddle is activated. If both paddles are closed simultaneously, the tuning rate increases to 20 kHz per second, with the tuning direction determined by which paddle was first closed.

Circuit Description

The MICROSIZER's circuitry consists mostly of CMOS ICs and is contained on a single-sided 4.8" × 5.3" PCB. The board has been designed for mounting in a Radio Shack Model 270-253 utility cabinet. Most of the parts are available directly from regular advertisers in *73 Magazine*. A PCB and some other selected parts can be supplied by sources listed in the parts list on page 82. Please note that the PCB layout printed here is copyrighted and reproduction by individuals for other than their private use is prohibited. Microcomputer interface or local control connections are through a 10-terminal connector on the rear panel. Other than an on/off switch, no controls are required on the front panel, making out-of-the-way placement convenient.

Circuit Operation

Refer to the block diagram in Fig. 1 and the schematic in Fig. 2 for the discussion to follow. The vco (voltage-controlled oscillator) operates directly at 5.0-5.5 MHz, using a high-Q varactor-tuned Colpitts circuit. The output of the vco drives the vco buffer, U3, and is then lowpass-filtered and applied to the transceiver. The output level is approximately 2.0 V rms across 1000 Ohms, a level compatible with the remote vfo input requirements of most transceivers. The output of the vco also drives a section of U3 used as a buffer, which is applied to mixer U2. Another input to the mixer is from the vcxo offset oscillator, U2, operating at approximately 5.9 MHz. The difference frequency from the mixer is in the 400 to 900 kHz range and is applied to U9, a Hughes HCTR-0320, containing a 3-stage programmable divider and a phase detector. The 100-, 10-, and 1-kHz BCD inputs to the programmable divider section of U9 determine the division ratio. The phase detector section of U9 compares the output of the divider with a 1.00000-kHz reference signal, converting any frequency or phase error to an error voltage to correct the frequency of the vco. The 1.00000-kHz reference signal is derived from a 4096-kHz oscillator and 12-stage binary divider, U1.

Thus, five hundred 1-kHz channels are produced over the 5.0-5.5 MHz range by varying the data to the programmable divider from 400 to 900. This data comes from 3 sections of a 4-section data register composed of U10 through U13. This register is a 4-decade up/down presettable counter with outputs from 0000 to 5000, corresponding to the five thousand 100-Hz channels. The output of the 100 kHz counter, U13, is modified by a section of U7 so that 4 is added to its output. Thus, the data presented to the programmable divider, U9, varies from 400 to 900 as the vco output varies from 5.5 to 5.0 MHz. The 100-Hz steps are produced by varying the frequency of the 5.9-MHz offset vcxo (voltage-controlled crystal oscillator) over a 900 Hz range in nine 100-Hz steps. This is accomplished by a digital-to-analog (D/A) converter (U8 and U18) controlled by BCD inputs from the 100-Hz section of the data register, U10. This scheme allows a lockup 10-times-faster than at least one commercially-available HF transceiver—without sacrificing frequency resolution. The data register can be clocked up or down at a fast or slow rate by circuits from U6 and U4. This is the mode of operation when microcomputer control is not used. The data register is automatically reset to 0000 each time power is applied to the MICROSIZER, preventing invalid BCD codes from upsetting U9. Microcomputer control is accomplished by utilizing outputs of a TTL-to-CMOS converter, U16, to program the BCD preset inputs of the data register. The two digit-select bits are also converted from TTL to CMOS levels by U16 and then decoded to one of four outputs by U15. U15 is enabled by a one-microsecond strobe pulse to load the data register with the BCD data present on bits 0-3 of the 8-bit inter-

face. As in the manually-tuned up/down mode, 0000 in the data register corresponds to an approximately 5.5-MHz vco output frequency. The 5.9 MHz offset vcxo is actually at 5.920 MHz so that 0000 will produce an operating frequency approximately 20 kHz below each amateur band, allowing plenty of margin for off-frequency heterodyne crystals in the transceiver. The software calibration routine adds a constant to the desired operating frequency to produce the "data frequency" that actually controls the MICROSIZER. Some transceivers, such as the Drake TR series, tune "backwards" on some bands, in which case 0000 would produce an operating frequency approximately 20 kHz above the high end of the normal tuning range of the vfo. This causes no major problems, because the operating frequency could be subtracted from a constant to produce the desired output data and tuning direction.

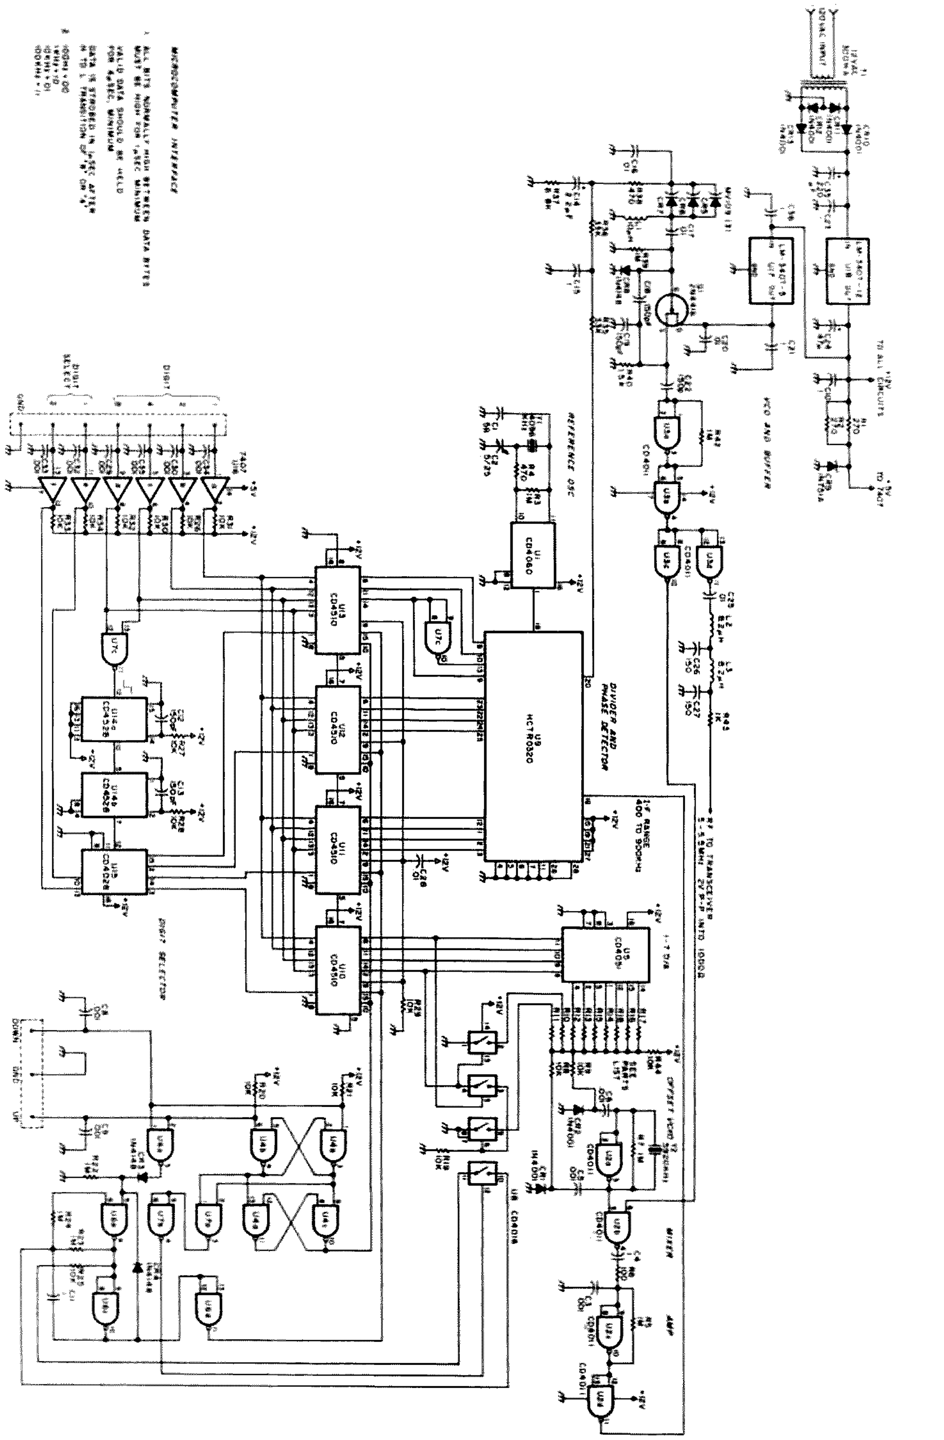


Fig. 2. Schematic of the MICROSIZER.

Power Supply

The vco operates from a regulated 5-volt source provided by a 3-terminal regulator, U17. The rest of the circuits operate from a separate 3-terminal 12-volt regulator. Five volts for the TTL-to-CMOS level converter is zener-regulated from the output of U18. Both 3-terminal regulators operate on 15 volts from the rectified and filtered output of a 12-volt transformer. A 10% variation in the ac line voltage causes no measurable shift in the output frequency. As is characteristic of all high-quality synthesizers, the frequency drift, even from a cold start, is very low, typically a few Hz. In the photograph of the spectrum of the MICROSIZER, note that the 1-kHz sampling sidebands are down more than 60 dB.

Possible Applications

The number of uses for a computer-controlled transceiver is limited only by the imagination. Here are a few seeds for thoughts. Many of you readers are programmers by profession and could develop these ideas more effectively than we.

Storage and Recall of Frequencies

Any of the 5000 channels in the basic 5.0-5.5 MHz range could be stored for instant recall by the computer. These frequencies could be catalogued as channel numbers, or with more meaningful designators (such as SSTV for 14.230 MHz or W1AW for 07.080 MHz). Some uses of this capability are:

1. Scanning selected frequencies for activity;
2. Split-frequency operation for DX;
3. Net operation and coordination.

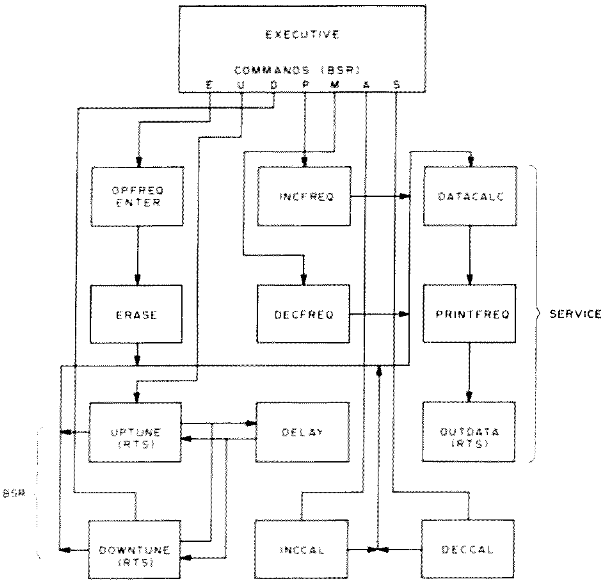

Fig. 3. Block diagram showing the functional arrangement of and linkage between the modules.

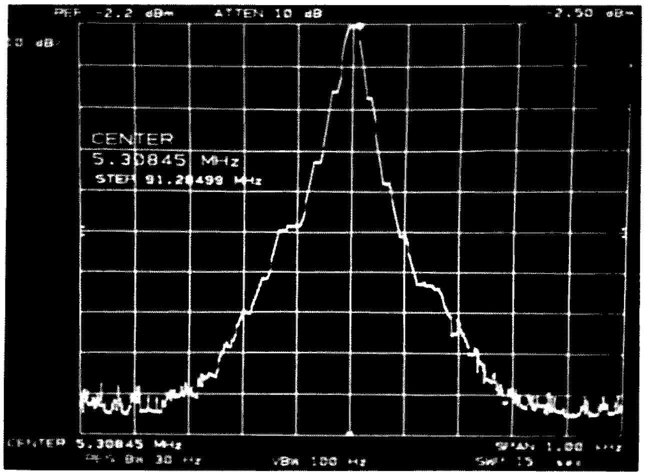

Spectrum analyzer photo of output.

Automatic Tuning

The transceiver could be swept automatically over any given band or band segment and at practically any tuning rate, ignoring undesired band segments. Out-of-band operation or operation on unauthorized frequencies can be detected by the tuning software, and an error message can be displayed to the operator. This would be especially useful during hectic contest or DX-chasing when the operator's attention sometimes strays. A similar frequency-recognization scheme could make the transceiver "hop over" foreign broadcast QRM on 40 meters or boring nets on 20 meters. With the computer's ability to decode CW, the times and frequencies of rare DX activity could be monitored and recorded continuously, especially during multiband single-operator DX contest operations.

Doppler Shift Correction For OSCAR-Relayed Signals

Using a variation of the automatic tuning mode, the transceiver could be tuned at the correct rate to track the Doppler shift of an OSCAR-relayed signal. Once a signal is initially tuned in, an OSCAR orbital prediction program and real-time clock in the microcomputer would determine the instantaneous Doppler shift and retune the receiver accordingly. The operator need only enter the geographic location of the transmitting station and the uplink and downlink bands.

Remote Control Operation

Virtually any microcomputer can be operated from a remote location by the addition of a simple modem and a remote terminal. This would permit

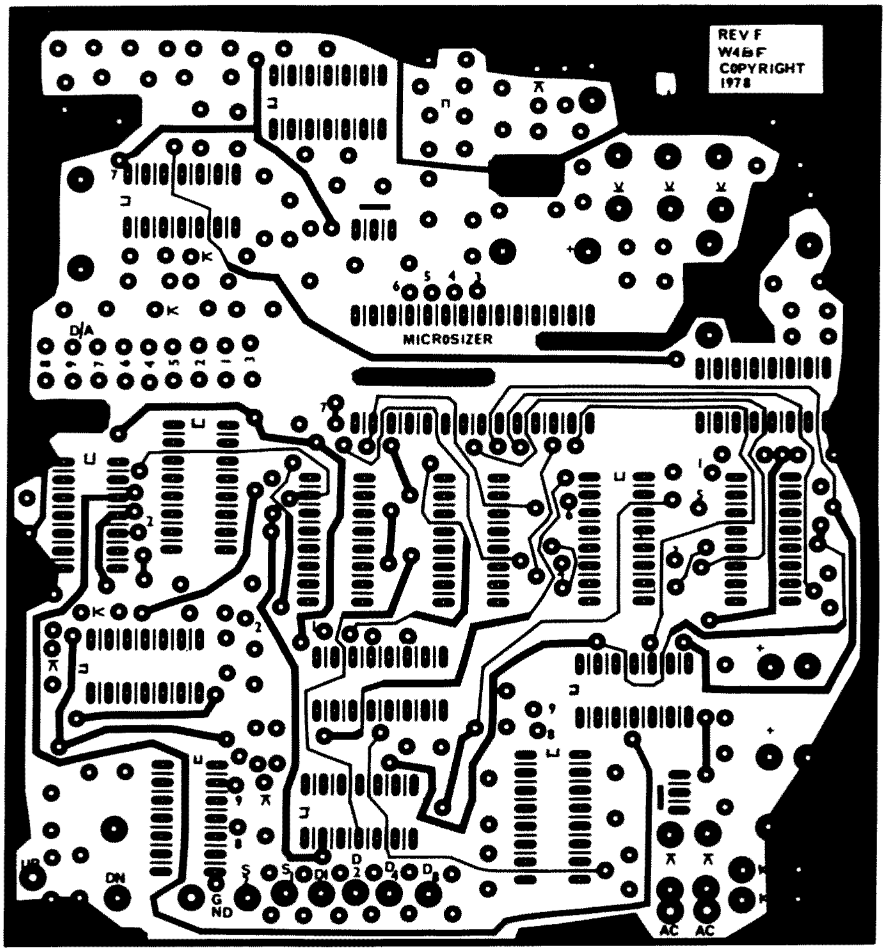

Fig. 4. Top view of PC board.

an operator to control the MICROSIZER and the other station functions from any location where an audio link could be established. The link could be either a telephone or radio system. Imagine operating your super DX station from your office telephone or through the local FM repeater! Unauthorized control of the system could be prevented by the use of classified "passwords" to limit computer access.

Improved Frequency Display

One common objection to digital readouts in conventional HF transceivers is the lack of visual "feel" when tuning. While tuning an analog dial, the operator can visually relate the operating frequency to other frequencies in the band. With a computer terminal serving as a display device, a simulated "dial" can be created with frequency calibrations and graticules moving left or right as the frequency changes. Some terminals even offer high-resolution color graphics, making possible some really "sexy" displays.

Some Software To Get You Started

OK, enough about our dreams. What have we really done? Well, desiring to develop some really useful software, but considering our lack of experience as programmers, we settled upon a few basic functions, which are:

1. Continuous CRT readout of the operating frequency;
2. Ability to tune continuously in 100-Hz steps;
3. Software correction for off-frequency heterodyne crystals;
4. Relocatable code;
5. Single 8-bit parallel interface.

This entire program was coded without the aid of an assembler, programming experience, or above average intelligence. Because each module of the program was developed and tested separately, this 500-byte program was only slightly more difficult to code than each of the short modules by itself. Our prime considerations obviously did not include fast program execution or ultra-efficient use of memory. An attempt was made to follow the basic guidelines of structured programming, but deviations were necessary because of the limitations of conditional branching in such a large program. Again, the program is modular in form, and branches between modules have been held to a minimum. The individual modules are simple enough for even the novice to understand. Each module may be modified to satisfy some special application requirement without disrupting the functions of the other modules. Because the program is relocatable, it should be easily integrated into any 6800 system having access to MIKBUG® or SWTBUG® routines and 520 bytes of RAM. Patches to other input-output routines will be very simple.

The Executive Routine (0030-007A)

The executive routine, as the name implies, is the master of this program. It monitors the system keyboard, decodes your commands, and calls upon the other modules of the program to perform various functions. Fig. 3 is a block diagram showing the functional arrangement of and linkage between the modules. Each module will be described in the text. The executive responds to the following commands: E—enter operating frequency; U—tune upward in frequency; D—tune downward in frequency; P—plus 100 Hz (single frequency step); M—minus 100 Hz (single frequency step); A—add 100 Hz to calibration offset; S—subtract 100 Hz from calibration offset.

Upon receiving an "E" command, the executive calls upon the "opfreq enter" module, which prompts with "FREQUENCY?" The operator enters six digits of frequency data. (Example: 142500.) Next, the "service" module adds this frequency data to the calibration offset (positive or negative), prints the operating fre-

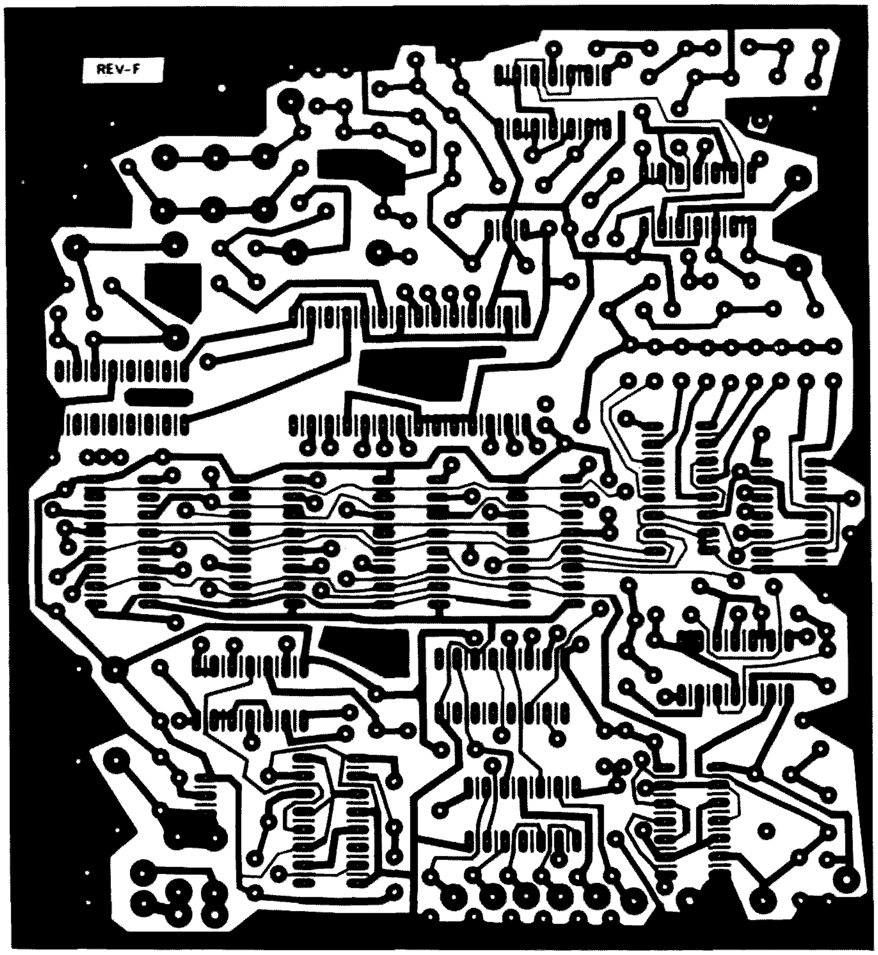

Fig. 5. Bottom view of PC board.

quency ("14250.0 kHz") on the CRT terminal, and outputs the frequency-controlling data to the frequency synthesizer sequentially through a single 8-bit parallel-output port.

A "U" command tells the executive to call upon the "uptune" module, a sort of "vice-executive" module, which in turn calls upon the "delay," "incfreq," and "service" modules repeatedly until any key is pressed, at which time program control is returned to the executive.

Similarly, on "D", the executive appoints "downtune," another vice-executive, to call the "delay," "decfreq," and "service" routines repeatedly until a key is pressed.

The "P" (plus 100 Hz) command tells the executive to call incfreq and service once only. The executive immediately resumes command of the program.

On "M" (minus 100 Hz), the executive calls decfreq and service, and resumes command.

On "A", the executive calls upon incal and service, and resumes command.

On "S", the executive calls upon decal and service, and resumes command.

Future plans include a much more powerful executive to control synthesizer, Morse transmit and receive, and QSO logging routines.

Erase Module (007B-0098)

The erase module, when called, erases the screen of a CRT terminal by outputting the proper ASCII control characters. This module also initializes the 6820 PIA of the synthesizer interface port.

Delay Module (00EB-00F4)

The delay module, called by the uptune and downtune "vice-executives," determines the tuning rate of the uptune and downtune modes of operation. The number of cycles of the delay loop, and therefore the time delay, is determined by the values of the two bytes of data stored at hex locations A022 and A023 of the system's 6810 scratchpad RAM. The maximum delay occurs when A022/A023 contain FFFF, allowing 65,536 loop cycles, for a delay of approximately 1.75 seconds.

Incfreq Module (0099-00B1)

The incfreq module adds one (100 Hz) to the BCD frequency data stored at hex locations 0000-0005. A BRA command always routes the program flow to the service module.

Decfreq Module (00B2-00D2)

This module subtracts one (100 Hz) from the BCD frequency data stored at hex locations 0000-0005. A BRA command always routes the program flow to the service module.

Inccal Module (01D6-01EE)

Inccal adds one (100 Hz) to the BCD calibration offset data stored at hex locations 0007-000C. A BRA command always routes

Program listing.

program flow to the service module.

Deccal Module (01EF-0207)

Deccal subtracts one (100 Hz) from the BCD calibration offset data stored at hex locations 0007-000C. A BRA command always routes program flow to the service module.

Opfreq Enter Module (00F5-012C)

The opfreq enter module utilizes the MIKBUG® / SWTBUG® OUTEEE routine to display "FREQUENCY?" on the top line of a CRT terminal. Next, using the monitor's INEEE routine, opfreq enter accepts six digits of frequency data, with the 10-MHz digit entered first, and the 100-Hz digit last. Opfreq enter does not accept decimal points or commas between the digits. The data entered is stored at hex locations 0000-0005, with the 100-Hz digit at 0000, and the 10-MHz digit at 0005.

Service Module (012D-01D5)

The service module is rather complex compared with the other modules of the program. For simplicity, this module was written and will be described as three separate modules that are unconditionally linked together. They are: datacalc, printfreq, and outdata.

Datacalc Module (012D-016D)

Datacalc takes the BCD operating frequency data at 0000-0005, adds to it the BCD calibration offset data at 0007-000C (positive or negative), formats this result for output to the frequency synthesizer, and stores it at 000E-0011.

Only four digits of data are required to drive the 05,000.0-05,500.0-kHz synthesizer, because the units (5) and tens (0) of MHz never change. Although the 5.0-5.5-MHz vfo of most HF transceivers tunes backwards, this reversal is handled by the hardware of the synthesizer. This software merely outputs the four least significant digits of the BCD operating frequency data, plus or minus any

calibration offset.

Printfreq Module (016E-01BB)

Printfreq, utilizing OUTEEE, displays the operating frequency data stored at hex locations 0000-0005 on the top line of the CRT terminal. The five most significant digits are output, then a decimal point, the last digit, and the letters "KHZ".

Outdata Module (01BC-01D5)

Outdata outputs the previously formatted BCD frequency control data stored at hex locations 000E-0011 to the 8-bit parallel-output port driving the frequency synthesizer.

Modifications

The uptune and downtune modules repeatedly monitor the system's control interface for the signal to stop tuning. An interesting alternative would be to monitor the parallel port connected to a tone detector used for CW receive programs. The program would stop tuning when a signal is found, and with a more powerful executive, jump to a CW receive routine. The address of the port to be monitored is stored at 00D8-00D9 and 00E4-00E5. The value of the "normal" byte found there is stored at 00D8 and 00E7 (no stop command or no signal). Any different value stops the uptune or downtune function and returns program control to the executive.

Construction

A full-size layout of the printed circuit board is shown in Figs. 4 and 5. Even with the double-sided board, it is still necessary to install 9 wire jumpers (number 26 wire) on the top of the board. Fig. 6 shows the jumper and component layout. Notice that the resistors are mounted vertically to conserve space. Plated-through holes are not used in the design, although if you make your own boards and have the facilities, you could do so. Our boards use "Z" wires to connect certain pads on the top and bottom sides. Fig. 7 shows the location for the "Z" wires, along with the method of installation. The cost savings of plated-through holes

Parts Availability

The following parts are available from MICROSIZER, PO Box 44, Cedar Rapids IA 52404: Double-sided, drilled G-10 PCB, tin-plated, $17.00; MV109 diodes, .75 ea. Hughes HCTR-0320 is available from Coombs Associates, 1001 E. Touhy Ave., Des Plaines IL 60018, for $14.70.

more than offset the inconvenience of the "Z"-wire installation. The rf output is routed from the pad on the PCB through miniature coax to an rf connector (RCA phono) on the rear. The PCB is mounted by removing the sheet metal screws that hold the rubber feet on the cabinet and replacing them with 5/8" 4-40 screws. The PCB is spaced off the bottom of the cabinet by appropriate spacers (or just #4 nuts on the top and bottom side of the board). The power transformer is mounted on the rear panel, using hookup wire to connect it to the PCB. Since the transformer was designed for PCB mounting, it is necessary to carefully bend the terminals so that they will not short to the chassis. An SPST toggle switch and ½-Amp fuse and fuse holder complete the mounting effort.

The vco inductor, L1, is mounted to the PCB with an insulated washer and a 5/8" 4-40 screw. Due to the tolerances in permeability of the toroid core, the actual turns required may vary by 1 or 2—so use the number called for in the parts list and remove a few if it is found necessary in the tune-up section. The two crystals are mounted directly on the PCB—just remember to solder quickly, in order to avoid too much heat on the pins.

Test and Alignment—Computer-Controlled

This step is easiest if you have the tuning program keyed in and ready to present data to the parallel data port connected to the MICROSIZER.

Apply the 120 V ac power and check for +12 and +5 at the outputs of the two regulators. Connect a frequency counter to the rf output jack and enter a frequency of XX0000. (Note that the first two digits don't really matter to the MICROSIZER—they are only for the CRT readout to indicate the tens and units megahertz.) The MICROSIZER should respond with a frequency somewhere in the range of 5.517 MHz. The exact frequency depends upon the frequency of the 5920 mixer crystal. However, this is not at all critical since the "A" or "S" calibration commands will correct the data frequency so that the MICROSIZER supplies the exact frequency to the transceiver to make XX0000 be at the bottom edge of any band. Monitor pin 9 of U1, the reference oscillator, and adjust the trimmer for 4096.000 kHz. Check the voltage at the junction of R35 and C15 (control voltage to the vco) for 11 to 11.5 volts. If necessary, adjust the number of turns on L1 or their spacing until this voltage is achieved. Next enter data XX5000 and check that the output frequency moved down exactly 500 kHz. The vco tuning voltage at this point should be between 5 and 6 volts. If everything

has checked out so far, input various frequencies and check that the 100 kHz, 10 kz, 1 kHz, and 100 Hz data move the frequency as it should. At this point, you should be able to connect the MICROSIZER to your transceiver and successfully perform all of the software operations available. Notice that the lockup time between 100-Hz steps is very fast and smooth, and tuning up or down is just like using a vfo, except that it's all done by the computer. Now enter a frequency and watch the CRT display show a jump to the desired frequency, accurate to within 100 Hz, in less than 100 milliseconds. Try that with a regular vfo! ! !

100-Hz Adjustment

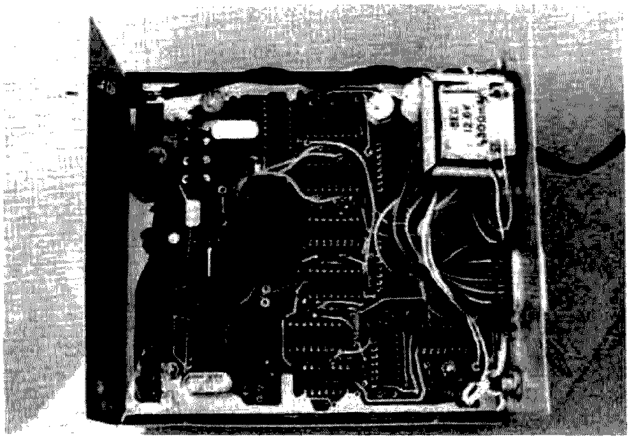
If your tests showed that the 100-Hz steps within a 1-kHz range were not accurate to within a few Hertz of the desired 100 Hz, some adjustment on the digital-to-analog converter may be necessary. The values for R10-R17 shown in the parts list may be juggled slightly to tailor the individual 5920 mixer crystal to the tuning diodes. Each 100-Hz step voltage is controlled by a single resistor, with the exception of the 900-Hz step, which is obtained by paralleling a resistor with the one used for the 800-Hz step. Table 1 shows the resistors and the 100-Hz steps that they control. If necessary, alter their values slightly—or, better yet, use a pot to determine the exact values, measure them, and replace each with a 1% unit.

Resistor	100-Hz Step Controlled
None	000
R17	100 Hz
R16	200 Hz
R18	300 Hz
R14	400 Hz
R15	500 Hz
R13	600 Hz
R12	700 Hz
R10	800 Hz
R11/R10	900 Hz

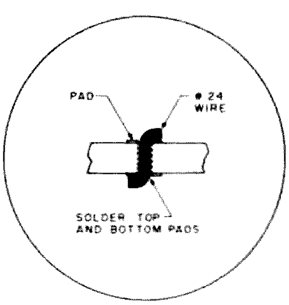
Table 1.

Test and Alignment—Manual Tuning Mode

If you don't have access to a computer to input data, you will probably need to measure the BCD output of the four data registers in order to determine their output to the divider chip and D/A converter. When the unit is first powered up, the registers should be all programmed with 0000, since C28 and R29 apply a 1-ms reset pulse when 5 volts first appears. Check that the output frequency is near 5.517 MHz, and zero the 1 kHz reference as described in the computer-controlled tune-up procedure. Now, ground the "up" tuning line, and the frequency should start changing in 100-Hz steps at a fairly slow rate. If the "down" line is simultaneously grounded, the tuning rate will increase. Momentarily remove power and reapply it to reset the counters to 0000; check



Interior view of MICROSIZER.



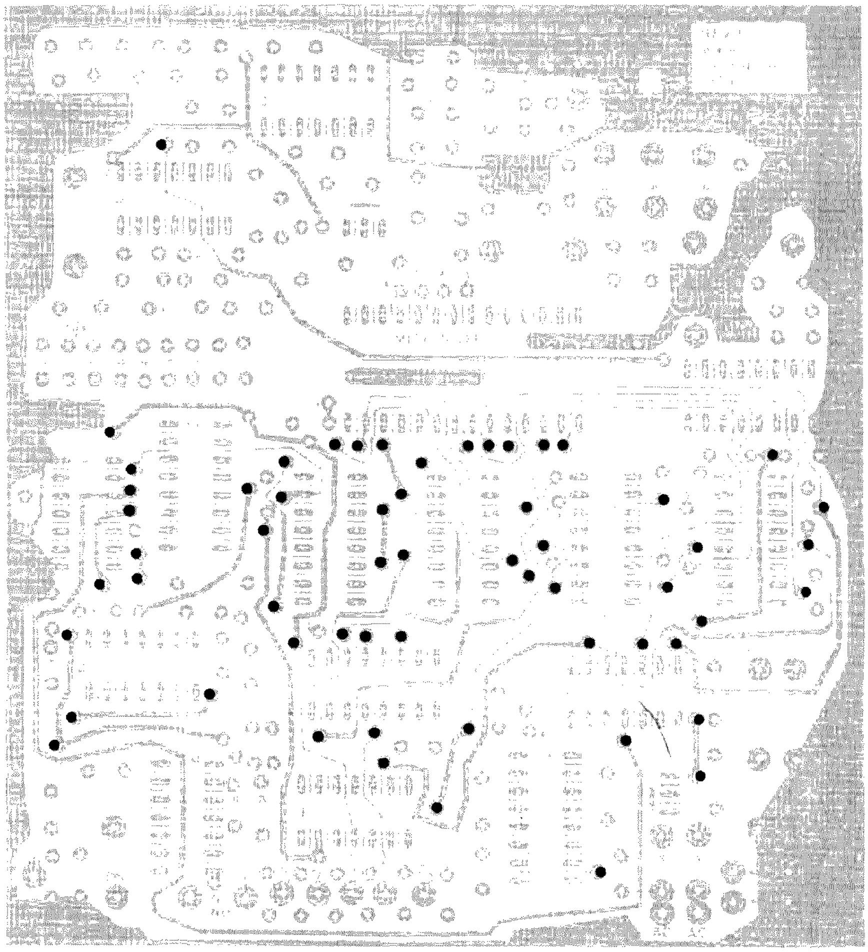


Fig. 7. "Z"-wire placement, along with method of installation.

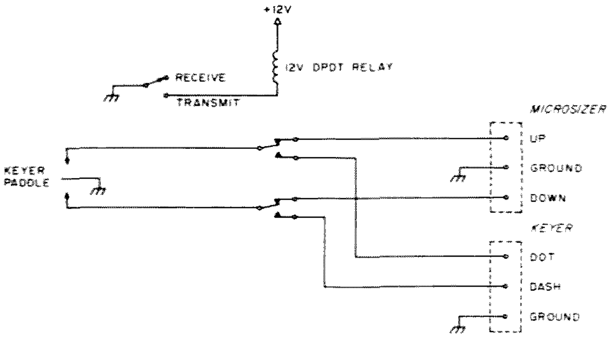

Fig. 8. Method for switching the keyer paddle between MICROSIZER tuning and keyer operation.

the vco tuning voltage as described in the computer-controlled tune-up procedure. Also, check the accuracy of the 100-Hz steps and vary the D/A converter resistors (R10-R17) if necessary. The tuning rate in the slow mode is controlled by C11; that in the fast mode is controlled by R25. They may be varied to adjust the tuning speed to suit your needs. If you are using your keyer paddle to tune, the simple circuit shown in Fig. 8 will permit it to tune the MICROSIZER in receive and operate the keyer in transmit.

Hopefully, this article will inspire radio amateurs to surrender the almighty tuning knob and discover the fascinating world of computerized "hamming." The possibilities are endless, and the cost of a computer is now less than that of a good transceiver. ■

CW Fans: Give Superior Selectivity to your Atlas Rig

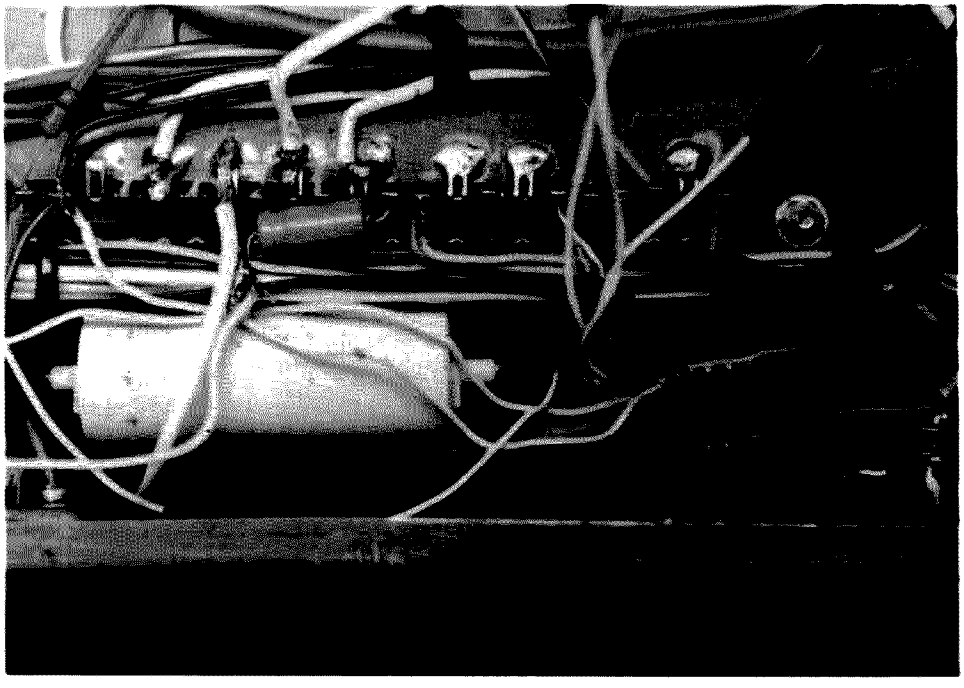
—this mod uses an inexpensive MFJ filter

Henry B. Ruh WB9WWM
Box 1347
Bloomington IN 47402

As have many other hams who enjoy the use of the great Atlas solid-state, no-tune-up rigs, I quickly discovered that while it was great for SSB, it lacked a little in CW reception ability. This simple modification will bring it around and make CW as enjoyable as sideband.

The Atlas rigs have a fine SSB i-f filter, but if you try to copy CW with this unit, you find that there is no original factory CW filter, nor any adjustments to narrow the i-f bandwidth. The problem of separating close CW signals by tone alone is difficult and frustrating, especially if you are a Tech trying to upgrade. (I finally got my Advanced using this rig on the Novice bands!)

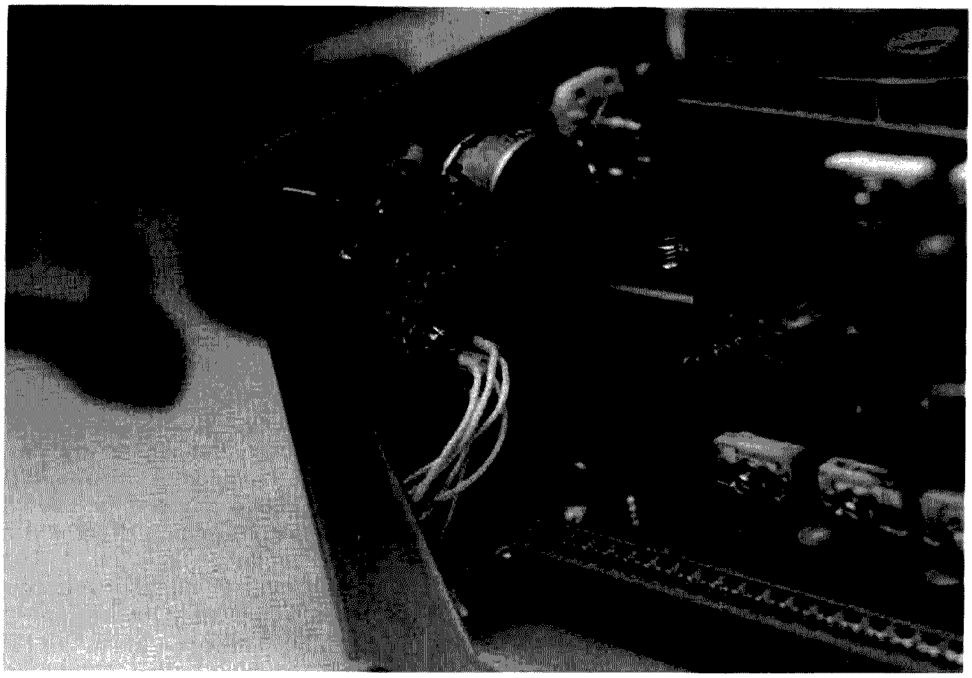
MFJ makes a dandy CW audio filter with a selectable bandpass which is centered at 750 Hz and which is also the CW offset of the Atlas, making it an ideal choice. While you could outboard the unit and keep buying 9-volt batteries for the filter, I found it could be placed easily inside the Atlas, deriving power and operational benefits from its location. While an audio filter is not as good as an i-f filter for CW, the performance of the hybrid unit when completed was more than adequate, and only the worst of QRM and zero-beating of signals could not be overcome. A more demanding CW operator would prefer the narrower i-f filter, but this works fine for most of us, and, since it can fit inside the rig, allows unimpeded mobile or portable operation.



Audio circuit connections, showing new wires and placement of the filter output capacitor (small electrolytic) in the center of the picture.

The MFJ filter, model CWF-2, like most MFJ products, comes in a small box and is powered by an internal 9-volt battery. Because of the small size and super compactness of the Atlas, there isn't much room inside for add-on goodies, but the MFJ fits.

The first step is to familiarize yourself with the operation of the MFJ filter. It employs a series of



Mounted bandwidth selector switch.

active audio filters using IC chips and matched components for a 750-Hz center frequency and a variable bandwidth of 180, 110, or 80 Hz. This allows easy copy without resorting to very low audio notes—nice in a non-CW rig—so you don't walk down the band, retuning to hear the other guy. The selectivity is chosen from a multi-position slide switch. The MFJ unit is designed for use either between audio stages or between the rig output and a headphone jack, supplied on the front of the MFJ box.

Modification Steps

1. To complete the conversion as pictured in the photos, follow these easy steps. No mechanical work is necessary unless you have the noise blanker option in your unit, in which case a single 3/8" hole is required.

The filter board is nestled between the speaker and the back wall of the chassis.

2. First, remove the screws holding the MFJ unit together. There are four, two on each side of the box.

3. Once the unit is open, you will see that the actual filter is contained on one PC board, held to the rear and bottom of the box with a rubber-like cement. Using an X-acto® or similar knife, carefully remove the PC board from the box. A wedging action between box and board is sufficient.

4. Remove the switches and headphone jack from the box by removing the four screws and a large nut holding the ¼" jack. The box should be set aside and all loose hardware stored in the bottom shell of the MFJ box.

5. Label or identify on the PC board each wire on the MFJ unit. There are two wires for power, + and −, audio in, and three audio out wires. The electrolytic capacitor attached to the multi-position switch is removed and saved for later use. After removal of the wires, the switches and connector can be remounted in the MFJ box. The box can be reassembled and set aside for other projects.

6. Remove both the top and bottom covers from the Atlas.

7. Remove the hole plug on the front panel below the NB (noise blanker) notation or, alternatively, drill a small (3/8") hole wherever you would like the bandwidth selector switch to go. A good spot is near the af/rf gain controls, positioned to allow as much room as possible for fingers to turn the knobs.

8. The switch selected for the rig shown in the photos was a Dale SP10T. A very small Alco or similar rotary with 4 positions is adequate. The Dale was in the ever-growing junk box. The type of switch used is the same as found on many HTs for frequency selec-

tion and is available from most parts houses, FM specialty houses, and ham stores. Spectronics (1009 Garfield, Oak Park IL 60304) has some for use on Motorola HTs for adding more frequencies. The cost is about $4.

9. Because the switch is really nestled in the rig, it is necessary to prewire the terminals. Five lengths of stranded no. 26 in your favorite colors, each about 14" long, will do nicely. Prepare the switch for insertion.

10. The PC board in the Atlas on the far right (facing front) is removed for insertion of the switch. This is the rf module, PC-100; or, if you have the noise blanker, find your hole and insert the switch as best you can.

11. The wires from the switch are routed to the front corner and down through the open space by the wafer selector switch to the underside of the Atlas. There is a channel in the rf cover over the vfo near the front lip which can serve as a cable raceway, or the wires can be run around the outside of the Atlas chassis over the audio board.

12. If you take the time and are neat, you can run the switch wires directly to the MFJ PC board. Or, use the wires attached to the MFJ unit and splice in midstream. Being naturally sloppy (according to the XYL), I chose to splice in midstream. The MFJ board slips between the speaker magnet and the rear connectors of the Atlas.

13. There is a red/white wire coming from the center terminal on the af level control which goes to the edge connector of the audio board in the Atlas. Remove the end attached to the edge connector. This is the input to the MFJ filter. This wire attaches to the #1 terminal (filter-bypass) position on the rotary switch. The audio input wire coming from the MFJ filter board is attached to the af level center terminal.

14. The output terminal on your selector switch is run to the vicinity of the edge connector and is connected to terminal 12 of the edge connector, using the electrolytic capacitor supplied with the filter (series connection).

15. The + power lead of the filter is connected to pin 21 of the edge connector.

16. The ground lead is attached to pin 18 of the edge connector.

17.The filter-select wires of the MFJ unit are connected to the terminals of the rotary switch in the order desired: 80, 110, 180, or 180, 110, 80 Hz.

18. The Atlas covers are replaced.

19. Turn on and enjoy!

Performance of the unit on the crowded 80- and 40-meter Novice bands was excellent. Needless to say, tuning the Atlas with the filter in the 80-Hz position makes for *fast* tuning. It was found that the 180-Hz mode was adequate for most work and tuning, and the 110-Hz mode was best for QRM-laden stations. The 80-Hz mode was something else, allowing you to hear the other stations chirp and drift with keying. You really can tell about vfo stability with the 80-Hz mode!

All in all, the unit performs very satisfactorily and makes a good SSB rig an even better all-rounder for those of us who only dabble in CW. The MFJ unit is currently priced at $29.95 and is available from a number of sources, including MFJ direct. ■

A Sensible CMOS TT Decoder

—presented by popular demand

C. Warren Andreason N6WA
PO Box 8306
Van Nuys CA 91409

Several years ago, *73 Magazine* published one of my articles titled "Autocall 76" (June, 1976). At that time, I offered printed circuit boards and the response was overwhelming. To make a long story shorter, over the time span, the circuit was redesigned using CMOS, and commercial printed circuit boards were developed.

While that circuit was intended for paging use, there were many letters asking how the circuit could be modified to work as a control circuit in a repeater with an on/off function. I designed a new circuit with a plug-in printed circuit board that meets this requirement.

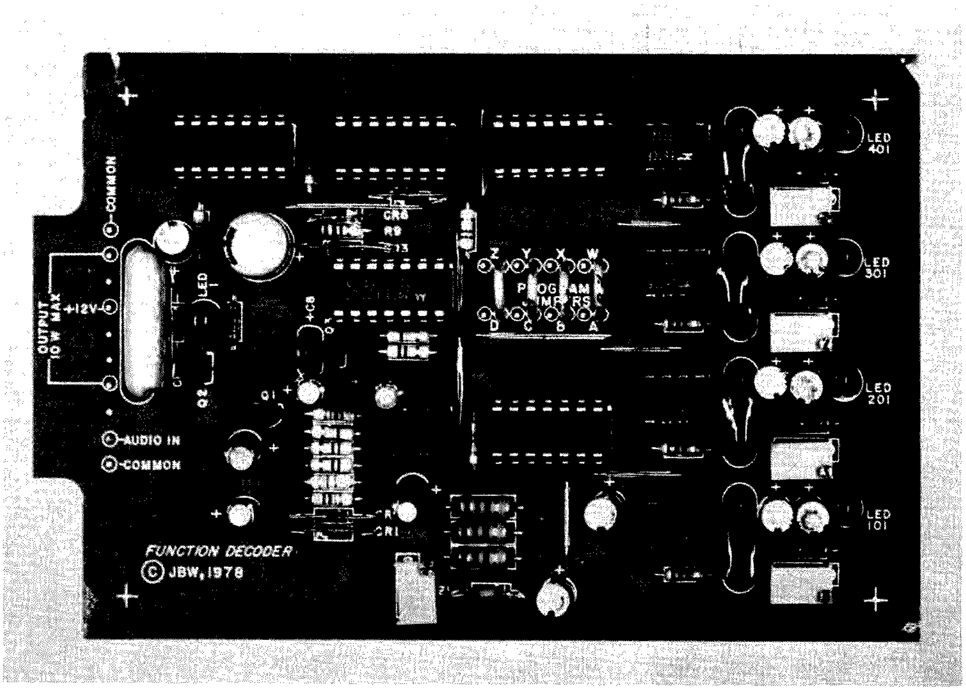


Photo of completed decoder.

This unit that is being presented is a totally self-contained single-function control board that requires only a 12- to 15-volt power source at about 100 mA and virtually any level of audio. The input is high impedance so it will not load or affect the audio line to which it is attached, and it adjusts its own input gain so that whatever audio input level is present is optimized for maximum performance. The output of this unit is in the form of a reed relay which can handle loads of up to 10 Watts. The relay contacts are isolated from all circuitry and may be used in any manner required. The circuit contains everything necessary for tuning and programming, without the need for test equipment. Once set up, the unit will respond to a four-digit touchtone™ code, latching the output relay, and releasing the relay upon reception of the proper and different four-digit off

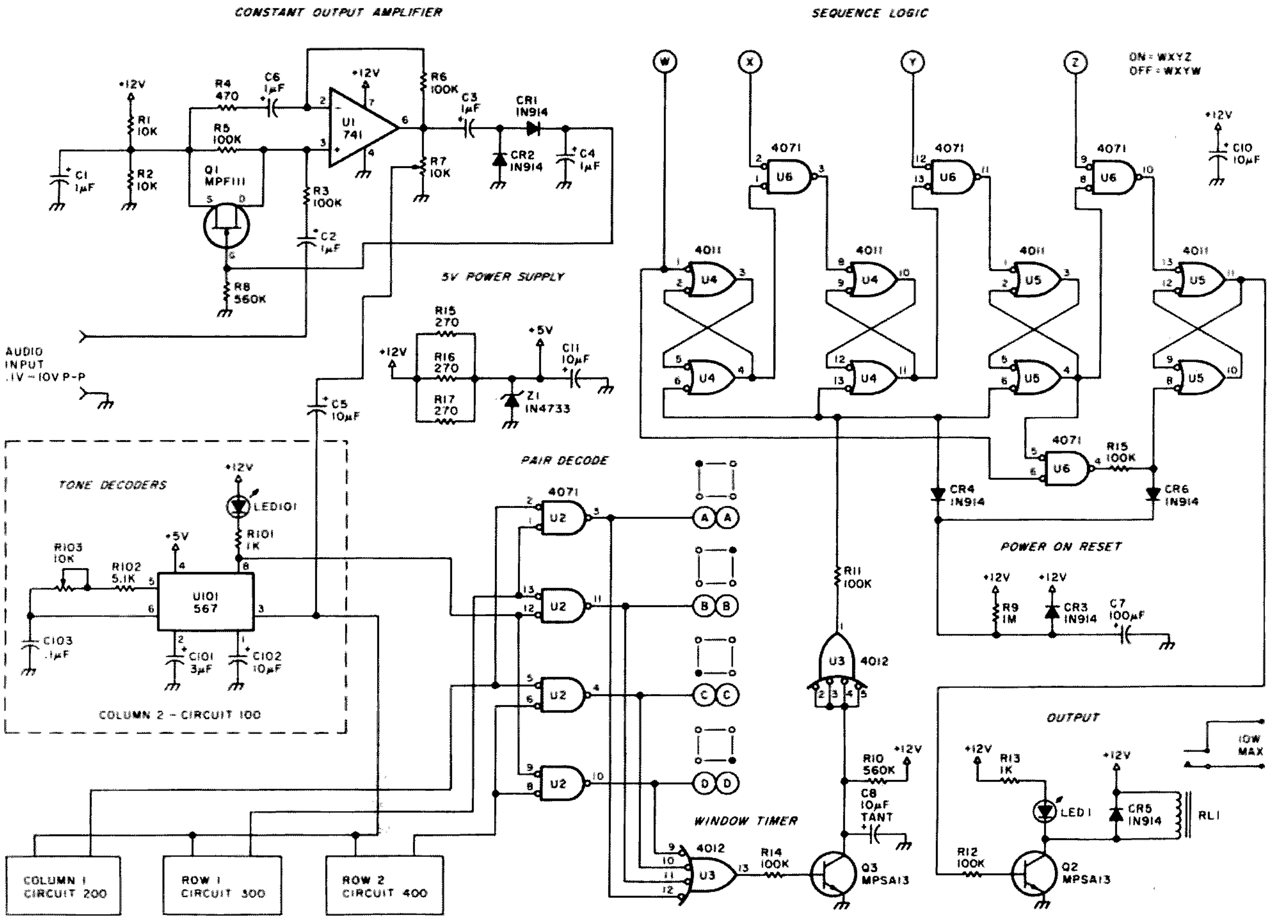

Fig. 1. Schematic of remote-control decoder. All resistors ¼ W, 5% unless otherwise stated. On all ICs, connect pin 14 to +12 volts and pin 7 to ground unless otherwise stated. Circuits 100, 200, 300, and 400 are identical except that part 101 becomes 201, etc.

code. This unit cannot be triggered by voices, yet will work even under the most trying conditions.

Circuit Description

See Fig. 1. The input stage of this function decoder is a self-adjusting automatic-leveling amplifier. It will take its input from any point which has audio available. The input impedance is on the order of 100k Ohms, so it will not load the audio line to which it is attached.

U1 forms a fixed-gain amplifier and the rectifier stage sampling the output produces a dc voltage level which is directly related to the output amplitude of the amplifier stage. This dc voltage is fed back to Q1, which turns on as the dc voltage goes in the positive direction. As the dc tries to go higher, the FET conducts more, shunting the input signal away from the amplifier input and not allowing the amplifier to produce any greater output.

In this way, the input stage regulates its gain to allow only small changes in the output, while the input may vary over a wide range.

The constant-level audio is fed to the inputs of circuits 100, 200, 300, and 400, which are tone decoders. Two of these circuits are tuned to column tones, and two to the rows. The desired decode tones are decided on and a touchtone dial (Fig. 2) is used to determine which columns and rows are needed. The leftmost column used will be referred to as column 1; column 2 is the rightmost. In a like manner, row 1 is the uppermost used row, and row 2 is the lowermost used row. Circuit 100 is tuned to the column 2 tone, circuit 200 to column 1 tone, circuit 300 to row 1 tone, and circuit 400 to row 2 tone.

These four decoded tones are fed into U2, (Fig. 1), which detects tone pairs and gives the digit-decode outputs. Output "A" would be row 1 and column 1; output "B" would be row 1 and column 2; output "C" would be row 2 and column 1; and output "D" would be row 2, column 2.

The decoded digits are fed to the W, X, Y, and Z inputs in the order in which the numbers are desired. An example would be the

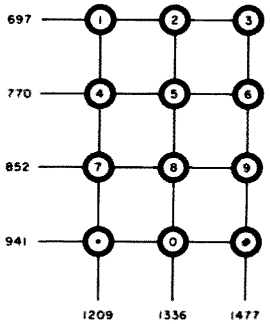

Fig. 2. Touchtone keypad showing row and column tones.

control number 1-3-7-9. 1 (column 1/row 1) output "A" goes to "W". 3 (column 2/row 1) output "B" would go to "X". 7 (column 1/row 2) output "C" would go to "Y". 9 (column 2/row 2) output "D" would to to "Z".

Anytime a digit is decoded, the output on pin

13 of U3 goes high, turning on Q3 and discharging C8. The low at C8 is inverted by the other half of U3, and is fed through R11 to the enable inputs of the sequence logic. As long as the enabling output from U3 is low, the sequence is held in a reset state, but the decoding of a digit and the subsequent discharge of C8 will enable the sequencing logic for a period determined by the charge time of C8.

If another proper digit is not received by the time C8 is charged by R10 (about 3 seconds), the logic is reset. As the proper sequence of digits is received, the flip-flops formed by U4 and U5 are set, in turn, until U5, pin 11, goes high with the proper decode of the fourth digit of the "on" code. When pin 11 is high, it drives the base of Q2, causing the transistor to conduct and relay RL1 to pull in. The relay will stay closed until the flip-flop driving Q2 is reset by the "off" code. The "off" code is the same as the "on" code except that the first digit of the code is also used as the fourth digit. If the code 1-3-7-9 were used as the "on" code, the "off" code would be 1-3-7-1.

LED1 in the collector of Q2 is a status light which allows the person looking at the board to know if the relay is energized. If the LED is lit, the relay is energized.

The network made up of C7, CR3, R9, CR4, CR6, R11, and R15 is used to provide power reset protection. In the event of a power failure, the unit will always come up in a mode where the relay is off (open contacts) when power is restored.

As mentioned earlier, this circuit is extremely effective and is in use in many repeaters, working as described. Some of the earlier units (based on the Autocall circuit with modifications for this task) have been on hilltops in repeaters and have been operating for several years without problems, so the circuit has been well proven.

In building this unit, it would be wise to select good temperature-stable components for operation in the area of the tone decoders. Resistors R102 and R103, and capacitor C103 must not change much if the tuning of the tone decoders is to remain stable. Show some care in handling and soldering of the CMOS logic, as I can attest to what a soldering iron with a leaky tip can do. If in doubt about your iron, ground the tip with a clip-lead near the handle. CMOS is great stuff but it cannot handle high voltage, even at extremely low current levels.

A final note of interest is that on the printed circuit card, the decoded digits, A, B, C, and D are brought out to a patch point and the sequencing logic inputs W, X, Y, and Z are also brought to the same point where convenient strapping is available for programming.

Professional PC boards and all components are available from CW Electronics (the author) as shown in the parts list.

Tuning—With Test Equipment

Provide an audio source and observe audio at pin 3 of any tone decoder on an oscilloscope. Adjust R7 until the audio peaks are about 200 mV. After deciding which tones to decode, connect a frequency counter which has a high-impedance input to pin 5 of each tone decoder (567), and, in turn, adjust each associated pot until the proper decode frequency is read as the vco idle frequency. This is done with no audio being fed into the unit.

Tuning—Without Test Equipment

Connect the audio input to a source of touchtones. Set R7 midrange and introduce the row 1 tone into the unit. This can be done by pushing two buttons of the touchtone pad simultaneously. Adjust pot R103 until the LED lights. Lower the adjustment of R7 until the LED goes out. Raise the adjustment of the R103 about 2 turns past the point where the LED lights again. Now, in a similar manner, provide the desired row or column tone, and adjust the other three tone decoders. R7 is set only once and just the tone decoders need adjusting. Make sure each tone pot is set in the center of the range, halfway between the drop-out points.

Jumpers

When all four decoders are set, decoded tone pairs will appear at outputs A, B, C, and D. Provide jumpers from A, B, C, and D to W, X, Y, and Z to obtain the desired order of decode, i.e., first digit to W, next to Y, and so on.■

DTMFR for your Repeater

—state-of-the-art TT decoding

O. C. Stafford K4ALS
3702 Holts Chapel Road
Greensboro NC 27401

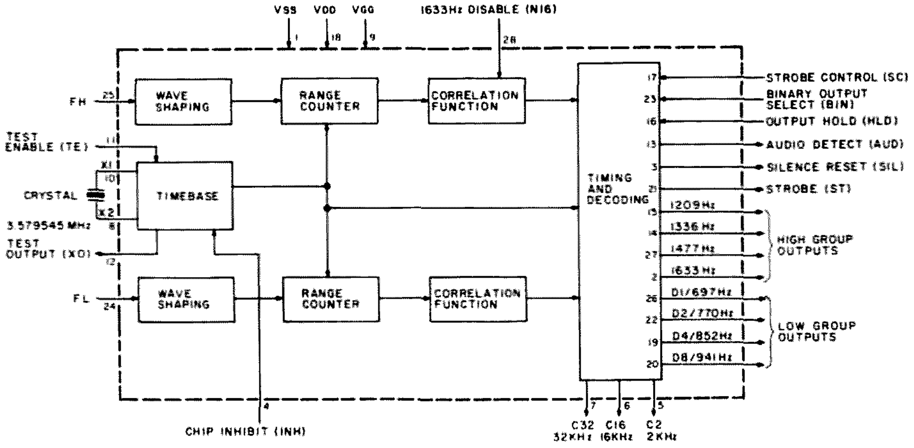

Fig. 1. CRC 8030 block diagram.

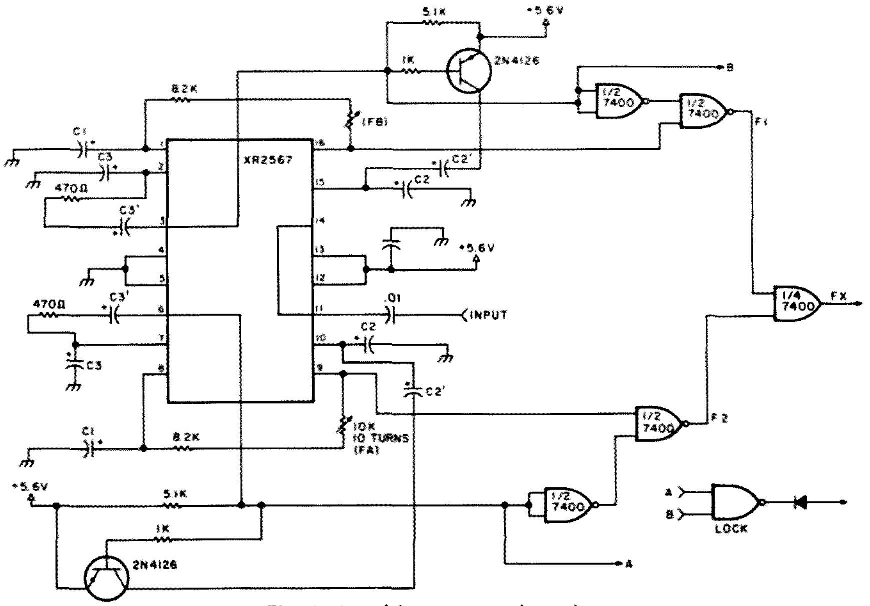

Fig. 2. Dual-loop tone decoder.

Decoding touchtone™ signals in a noisy environment can create real problems. Having the autopatch come up in the middle of a rag chew or turning on the air conditioner in the middle of winter can be embarrassing.

The development of the NE 567 by Signetics, the XR 2567 by EXAR, and the Mostek MK 5102 simplified the hardware required to construct tone decoders. Now you can replace the NE 567 and XR 2567 combos with a single chip—the CRC 8030 made by Rockwell-Collins. The chip costs more than the MK 5102, but then it does more and has more output functions.

When coupled with a suitable front end section, you can make a dual-tone multi-frequency receiver (DTMFR) that has fast lock-up time, practically no false outputs, and a few other features that will be discussed later. Pin connections for the CRC 8030 are shown in Fig. 1.

Fig. 3 shows the block diagram of the unit. I built three filters for use with the CRC 8030, but the one shown here seems to be the easiest to adjust and maintain. This circuit also produced some circuit tips that can be added to the decoder circuit described

by Buffington (*73 Magazine*, April, 1977), to decrease the lock-in time.

A single-stage agc amplifier drives XR 2567 dual-tone decoders. The decoders form bandpass tracking filters for the two tone groups. A simplified diagram of the filter circuit

Fig. 5. Touchtone matrix: binary outputs.

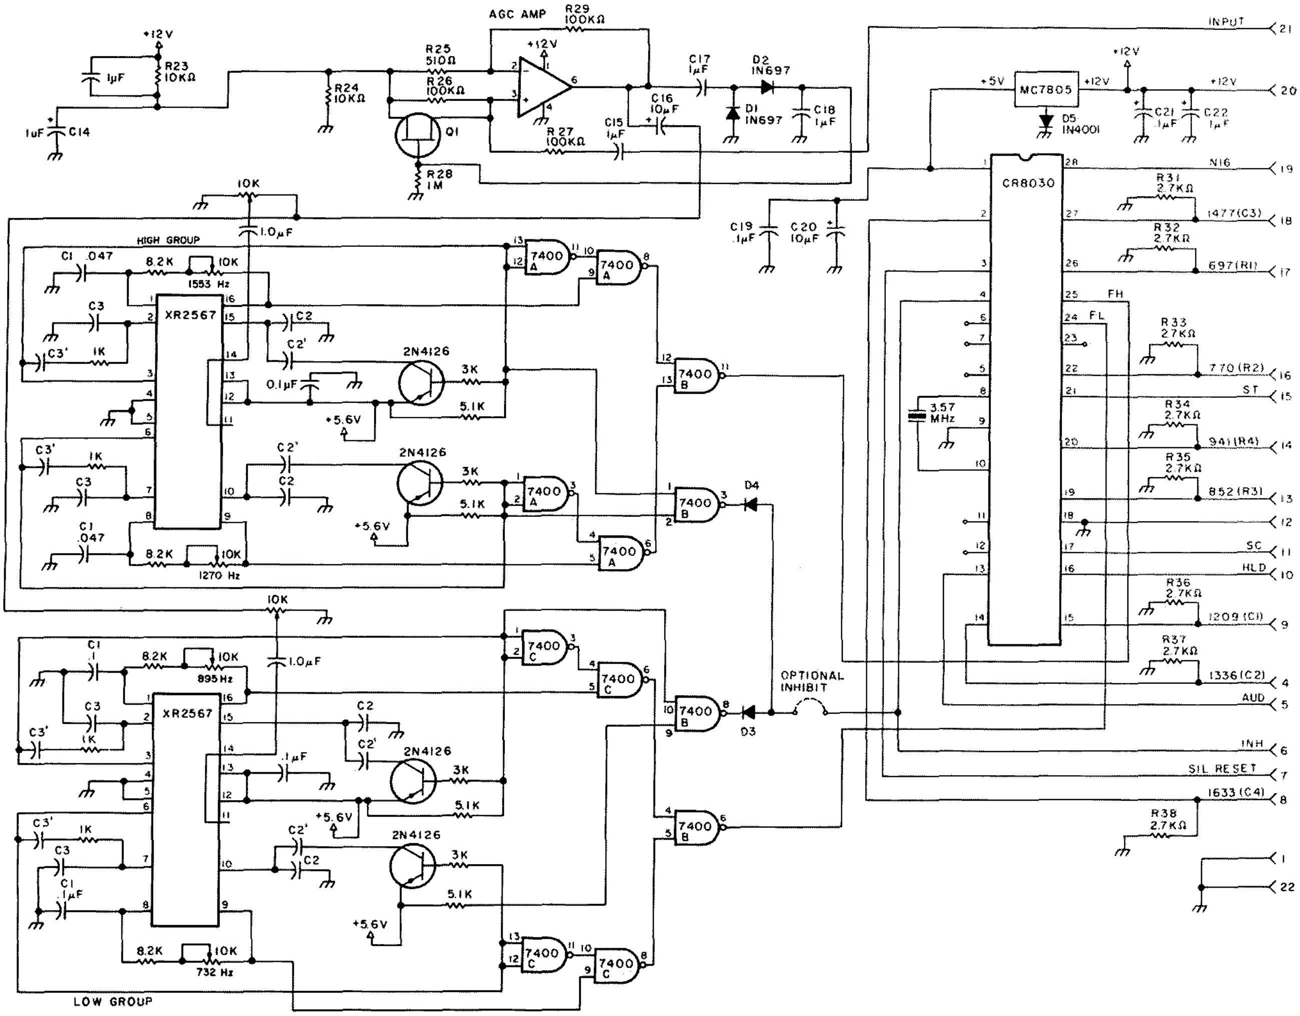

Fig. 6. Schematic of DTMFR. Values for C2, C3, C2', and C3' are found in Fig. 4.

is shown in Fig. 2. Each decoder has two control loops. When no signal is being received, the decoders are free-running at the center frequencies shown in Fig. 4. The smaller value for the loop filter capacitor allows the unit to lock faster. When a tone appears within the passband and the first lock occurs, pin 3 or 6 goes low and the second loop takes over, reducing the bandwidth and over shoot. It's like driving at 90 miles per hour and stopping immediately, if not sooner. In other words, the bounce is gone! After this occurs, the output of the locked decoder is then gated to the CRC 8030.

The CRC 8030 examines the input signal and, if it likes what it sees, generates a strobe pulse to indicate valid data, and all within 40 ms! Whenever a signal is present, AUD (pin 13) goes low to indicate a tone is present. The SIL (pin 3) stops sending out 10 millisecond pulses. Output can be 2-out-of-8 or binary if the BIN (pin 23) is held low. Binary output format is shown in Fig. 5. The output can be stored in the output register if HLD (pin 16) is held low.

I decided to use the INH (pin 4) to inhibit decoding of any tones unless a tone from each group is present. Neat, huh?

Adjustments

Adjust the four decoders to the free-running frequencies shown on the chart of Fig. 4 by first grounding pin 3 or 6 of the respective decoder. Next, apply a single tone of approximately 1 volt to the agc amplifier and adjust the low-tone group control for 1 volt at the input to the decoder for that tone group. Repeat this procedure with the high-tone group.

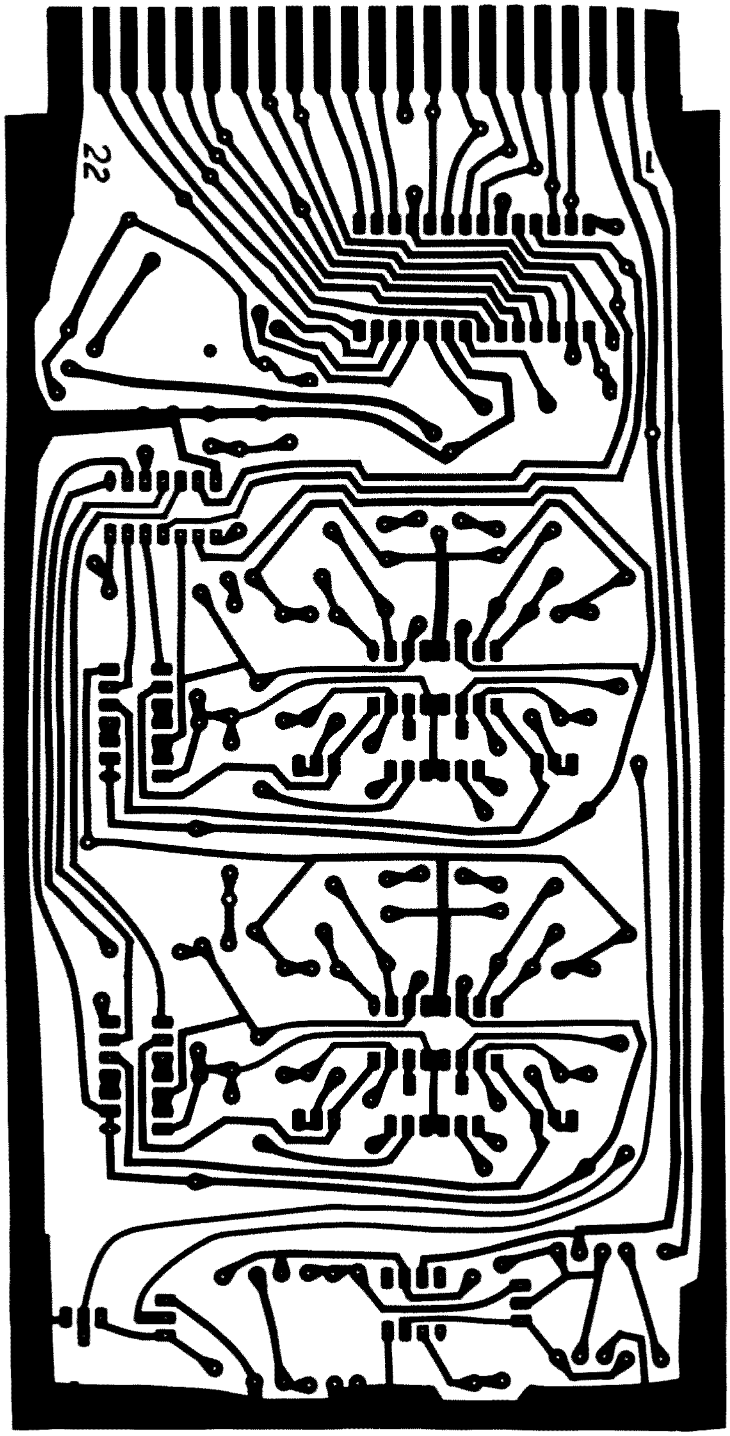

Fig. 7. PC board.

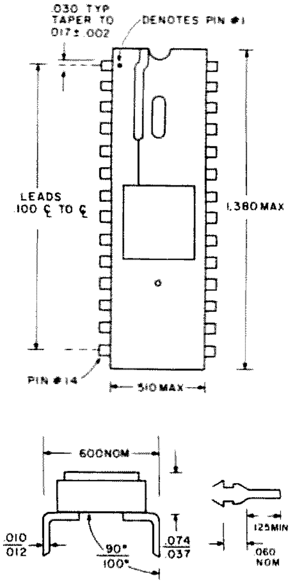

PIN NO	FUNCTION	PIN NO	FUNCTION
1	VSS	15	1209 Hz
2	1633 Hz	16	HLD
3	SIL	17	SC
4	INH	18	VDD
5	C2	19	D4/852 Hz
6	C16	20	D8/941 Hz
7	C32	21	ST
8	X2	22	D2/770 Hz
9	VGG	23	BIN
10	X1	24	FL
11	TE	25	FH
12	XO	26	D1/697 Hz
13	AUD	27	1477 Hz
14	1336 Hz	28	N16

Fig. 8. DTMF detector (CRC 8030).

The agc amplifier should handle signals from 50 millivolts to 5 volts while holding the output constant.

The dual-lock circuit for the XR 2567 can be incorporated in existing systems without too much trouble and cost. With this circuit, it is possible to use a standard card dialer which would make autopatching a lot easier and safer while mobile in motion.

Further improvements can be made to the front end by using separate agc amplifiers with suitable filters for each group. I would appreciate any and all comments on this circuit.■

Freedom Fighters on Forty

—SWLing the anti-Castro clandestines

Harry L. Helms, Jr. KA5M
3002 Valley Meadow, Apt. 144
Dallas TX 75220

Hams by their very nature are "talkers," whether by SSB, FM, CW, or RTTY. I love to yak, too, and that desire to talk is one of the main reasons I wound up with my ticket. But there are times when listening is far more rewarding than speaking, and I can't help but wonder how many hams are aware of some of the remarkable things which could be heard on 40 meters during the first six months of 1978.

My mike and key gathered dust for several weeks as I spent my operating time searching the 7070-7100 kHz range for a Spanish-speaking OM who identified himself as "El Comandante David." His station used no call letters, only the slogan "Radio Rebelde." David did not engage in the usual ham QSOs; rather, he used his station to deliver impassioned and moving speeches against the regime of Fidel Castro in Cuba. As I listened to Radio Rebelde's broadcasts, I found myself becoming emotionally involved with David's situation, hoping desperately that he would manage to avoid detection by the authorities for another night.

David was a Cuban radio amateur. Radio Rebelde was a Cuban ham station pressed into service as a broadcasting station. David faced the death penalty for treason if caught by the Cuban government.

I entered the ranks of ham radio after several years as an SWL (shortwave listener). Unlike many hams who get their start in SWLing, I have never lost interest in the hobby and still belong to a number of SWL clubs. Thus, I was aware that interesting things do pop up from time to time in the 40 meter band. Almost yearly, some teenagers get ahold of an AM phone transmitter like the DX-60 or Johnson Ranger and set up a bootleg broadcasting station for a few days (one I particularly remember took to the air in 1973 under the callsign "WTIT, The Sound of Young America!"). During the first few years following Castro's rise to power in Cuba, 40 meters was the site for several low-powered freedom stations operating from various locations inside and outside Cuba (SWLs refer to such hidden stations as "clandestines"). But such activity decreased during the 1970s, with the last activity I can recall having taken place in 1975.

But recently Castro has become much more venturesome. Despite the continuing stagnation of the Cuban economy and hardships suffered by the Cuban people, Castro decided to launch large-scale involvement of Cuban troops in Africa. American sources estimate that over one-quarter of Cuba's armed forces are currently involved in Africa and the strain upon the homefront is reportedly severe. Goods and services, which have long been in short supply, have in some cases become virtually unobtainable by the average citizen. Moreover, certain portions of Africa, particularly Angola, are becoming as difficult for Cuba to extricate itself from as Vietnam was for the United States. Casualties are high, especially among black troops in the Cuban army, and this has resulted in smoldering racial tensions within Cuba.

Given such a backdrop, it was perhaps inevitable that some form of new anti-Castro clandestine radio activity would spring up. The first inkling came in the pages of *FRENDX*, the monthly bulletin of the North American Shortwave Association (PO Box 13, Liberty, Indiana 47353). During November of 1977, several SWLs reported hearing a station identifying as "Radio Abdala" operating in the AM mode on frequencies centered around 7085 kHz. All broadcasts were in Spanish, using male and female announcers reading scathing critiques of Castro and communism in general. Its theme music played at sign-on and during station breaks was from "2001, A Space Odyssey." It claimed to be operating from within Cuba itself, but most listeners doubted this, if for no other reason than its

elaborate and professional production. A better guess placed the transmitter either in southern Florida or somewhere in Central America. "Abdala" turned out to be the title of a well-known Cuban exile group.

Yet another anti-Castro clandestine was heard by a Miami SWL during December, 1977, operating in the 7000-7025 kHz range. The Miami SWL, Timothy Hendel, recorded one of his receptions and forwarded the tape to well-known SWL Glenn Hauser, editor of the "Listener's Notebook" section of the *FRENDX* bulletin. Glenn was able to glean from the tapes such tidbits as the announcer claiming to be operating from the Oriente Province of Cuba "especially for the Revolutionary Armed Forces." The station indentified itself as "Radio Rebelde, unida a Radio Libertad Cubana" and the announcer referred to himself simply as "El Comandante David."

I noted such reports with interest, but was unable to find either Radio Abdala or Radio Rebelde during checks during January of 1978. The two stations gradually began to fade from my memory until the evening of May 5, 1978. I was tuning 7080 kHz around 0300 GMT when I ran across an AM station badly QRMing the Europeans trying to work the states on SSB. Despite my best efforts to tune out the pest, his strong signals continued to obliterate 7080. I flipped the mode selector on my rig to AM and decided to see if I could identify the lid.

Something about the announcer's voice immediately caught my attention. It was strident, urgent, emotional. I found myself struggling to remember the Spanish I took as a college freshman. Certain words kept popping up clearly in his speech: "Cuba," "Angola," "Sovietica," and "la tirania de Fidel Castro." I now realized what I must be hearing, and it was soon confirmed with the identification as "Esta es Radio Rebelde, unida a Radio Libertad Cubana."

I heard Radio Rebelde again on May 9, and on May 10 I heard both Rebelde and Radio Abdala. By this time I was hooked on listening for these two stations. I caught Radio Abdala on May 10 at 0135 GMT on 7080 kHz. Both male and female speakers were heard, and talks were interspersed between musical breaks. Signal strength was excellent, yet modulation was quite crummy. I kept listening until they signed off at 0210. At 0253 on 7088 kHz, I again caught Radio Rebelde and David at the mike. He seemed to be having some sort of transmitter trouble this night, as the carrier left the air several times while he was speaking. Once it returned on 7089.5 kHz. David left the air promptly at 0300 and was heard no more that night.

I tuned for both without success on May 11, but again caught both on May 12. This quickly developed into a pattern; if one station was on, the other was sure to be on later that night. Radio Abdala was caught at a 0122 GMT tune-in on 7082 kHz while Radio Rebelde and David were heard beginning at 0201 GMT on 7089 kHz. David was rapidly proving the more interesting of the two stations. His voice delivery was seemingly extemporaneous, and frequently there were moments of dead air while he seemed to collect his thoughts. He claimed to be broadcasting from a hidden location in the mountains of Oriente Province and that there was a large underground in Cuba ready to rise up against Castro. He attacked the shortages of goods in Cuba and accused the Cuban government of falsifying casualty reports for its African operations.

I couldn't help but wonder if David was a radio amateur like myself. On May 12, I found out. At 0325 David paused and his carrier left the air for a few moments. Another Spanish-speaking voice came on frequency, mocking David and asking, in effect, "Why don't you give up? No one is listening to you anyway!" Immediately David's voice returned to the air, angrily challenging the unidentified intruder. No, no, that's not the case, claimed David. Radio Rebelde had "muchos, muchos oyentes" (many, many listeners). Thus wound up, David once again tore into the Cuban government and Castro until 0400 GMT, when he signed off and thanked his listeners.

David had to be listening to his transmit frequency in order to hear his heckler, indicating that he was operating transceive. That little incident convinced me that Radio Rebelde was actually a CM/CO amateur station in disguise.

As May wore on, I could hear both Radio Abdala and Radio Rebelde two to four times per week. I began to note that David was being subjected to "jamming" of a sort, such as swishing vfos and rough ac-modulated tones almost zero beat with his signal. At the time, I merely chalked these up to noodle-brained stateside hams.

On May 24, I caught a new voice on 7090 kHz from 0152 to 0159 GMT. This speaker was definitely not David, but another Spanish-speaking OM attacking Castro. At sign-off, I caught a clear identification as "Radio Libertad Cubana," the station supposedly "united" with Radio Rebelde. I felt exhilaration as I realized that David was not alone, that there were others inside Cuba who were working with him. And the very next night, May 25, David and Radio Rebelde were back on 7090 kHz until 0300 GMT.

About this time, I was seized with an almost irresistable urge to communicate somehow with David, to let him know that his message was being heard outside the boundaries of Cuba. From several sources, I was able to form what I feel to be a reasonably accurate guess as to the true identity of David and his amateur callsign. Writing a letter was obviously out, due to the chance it could be intercepted by Cuban authorities. I toyed with the idea of ignoring several FCC rules and using AM phone on David's frequency, sending him greetings in Spanish. I decided, however, to stay within the rules.

In retrospect, I wish I hadn't.

Things came to an abrupt head on June 2. At 0235, I caught David and Radio Rebelde on 7080 kHz, 10 kHz lower in frequency than normal. His subject, as near as I could determine with my limited Spanish, was the growing influence of Castro in Venezuela and his designs on that nation's large oil supplies. But, at 0238, he was suddenly QRMed by an English-speaking OM using the call CM2HB, calling CQ for stations in Europe. CM2HB was using SSB, but his signal was so perfectly placed atop the AM signal of Radio Rebelde that he could be copied without using a product detector. CM2HB and Radio Rebelde were identical in strength, and CM2HB continued to call CQ for several minutes. The operator of CM2HB

had to be aware of Radio Rebelde on the same frequency, and I knew his choice of frequency could not have been purely accidental.

At 0253, CM2HB got tired of CQing and left the frequency. In his place popped up someone swishing his vfo across the frequency. Through the QRM, I could hear David's voice thanking listeners for their letters. I couldn't help but wonder if this wasn't just some wishful thinking on the part of David, since if the listeners could figure out how to get a letter to Radio Rebelde, the Cuban authorities surely must also have had some inkling as to the identity of David. David exchanged bits of conversation with another Spanish-speaking station, but the talk was too fast for me to follow. Abruptly, at 0258, Radio Rebelde left the air.

I tuned the 7080-7090 kHz range for several minutes before I caught an open carrier on 7080. At 0315, Radio Libertad Cubana came on the air, picking up Radio Rebelde's theme of Cuban influence in Venezuela. I was never able to catch the name of the announcer for Radio Libertad Cubana, but it was not David's voice that I heard. I didn't get the chance to listen to much of Radio Libertad Cubana this night, for, at 0317, several stations suddenly came on the frequency, all using CW. There were four or five stations, all neatly spaced in the bandwidth of the AM signal so as to completely destroy the intelligibility of Radio Libertad Cubana. I switched my receiver into the CW with a narrow bandpass filter and found that each of these CW stations merely sent CQ over and over without signing any call. At 0325, Radio Libertad Cubana left the air and the mystery CW stations likewise ceased operations.

The rest of the evening was a confusion of jumbled activity on 7080 kHz. At 0330, I caught David's voice again, engaging in a brief QSO with another Spanish-speaking amateur using the AM mode. At 0335, Radio Rebelde again took to the air, with David this time sharing the mike with another male announcer. As soon as he began his transmission, David was jammed by a couple of other stations which began sweeping their vfos across his frequency. At 0345, Radio Rebelde left the air as David wished all his listeners a good night and thanked them for listening.

To date, I have not heard Radio Rebelde, Radio Libertad Cubana, or Radio Abdala since.

I have carefully searched 40 meters in the months since June 2, 1978, many nights, but have failed to hear David's distinctive voice once. Nor have any receptions of the three stations appeared in the bulletins of any of the SWL clubs that I belong to.

It could have been that David and his compatriots simply got tired of their activity. Or the jamming activity of June 2 could have indicated to them that it would be best to lie low for a while. A much more ominous possibility is that some of them are currently in a Cuban prison or even dead.

But if David or some of his friends should somehow read these words, I hope that someday he'll return to the air to let his listeners know that he's still all right. And if you should come across an AM station in the CW portion of 40 meters some evening, stop and listen. It could well be David. ■

The Miserly Mobile PVC Special

—radiates a very economical signal

A quickie-cheapie for 2m.

Richard L. Hladky AA4RH
Rte. 2, Box 240
Summerland Key FL 33042

Want a quickie-cheapie two meter antenna for your car? One that doesn't need a ground plane, and makes a near-perfect match to the feedline? Try this:

Take a piece of RG-59/U coax, long enough for your feedline plus about ten feet. Trim the outer cover back about two feet. Carefully expand the braid by pushing from the free end to enlarge the diameter to about twice its normal size (but don't unravel the braid). Now, work the braid down over the top of the outer covering of the coax, so that the braid is folded back over itself over the outer covering. When it is all smoothed down, trim the length of the braid to one-quarter wavelength for the frequency you want (19.25 inches for 146 MHz). Tie or tape the braid in place.

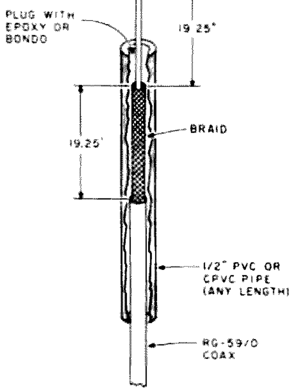

Fig. 1.

Next, cut the exposed center conductor and insulation about two inches from the folded-over end of the braid. Remove the insulation except for about an eighth of an inch. Now cut a piece of brazing rod (or #10 copper wire) to a quarter wavelength and solder it to the free end of the center conductor of the coax, with the rod butting against the insulation. Tape, or use heat-shrink tubing on the joint.

See what you have now? A half-wave antenna fed at the center, and matched to the coax it's made from.

Now take a quick trip to the hardware store and get a piece of ½" PVC or CPVC pipe. Cut it to the length you want for your finished antenna. Insert the end of the antenna through the pipe so that the rod protrudes about twelve to fourteen inches. Plug the end of the pipe around the rod with auto body filler (such as "Bondo") or epoxy. After this sets up, you can pour the rest of the pipe full of fiberglass resin if you want, but it isn't necessary if you've put a good plug in the rod end. (CPVC material seems to slow the setting of fiberglass resin, but it will set up in time.) All you need now is the appropriate fitting for the other end of the coax, and you're on the air.

The swr on my antenna is practically the same across the entire band, about 1.3:1. I have it in a six-foot piece of pipe which gets me well above the car body, so its pattern is not distorted by the metal of the car. And it is much more effective than the quarter wave I used to have on the roof. The CPVC pipe is flexible enough to bend almost double if I forget to take it down before going into the carport (but the noise is terrifying!).

The same approach works well for an antenna for the home rig, but if you're going to have a very long feedline (over about 25 feet), you should use RG-11/U coax. It's next to impossible to pull the braid on this coax back over itself, so the trick is to cut off a couple of feet of coax, take the braid completely out, expand it, and slide it over the piece you're going to use as a feedline. You can then solder the braids together, and I find it protects the outer covering of the RG-11/U if you work a small piece of fiberglass cloth under the place you're going to solder. The braid will easily expand enough to pull it over the top of a couple of layers of cloth.

This is a good project for a rainy Saturday. The antenna works well, is cheap, and, with a little care, can be made good-looking. Try it! ■

FSK Fix for the 820S

—the RTTY relay remedy

Talk up this "talk it up" solution.

Hugh Aitken W1PN
155 Amity St.
Amherst MA 01002

One of the many attractive features of the Kenwood TS-820S transceiver is the fact that circuitry for FSK (frequency shift keying) is already built in, so that the owner who wants to operate radioteletype has no need to start digging around in the vfo or local oscillator. Additionally, when in the FSK mode, one can use the very sharp 500-Hz CW filter and get really remarkable selectivity. When transmitting FSK, the rig even automatically cuts down the power to a level safe for continuous service.

There is, however, one slight difficulty. To key the transceiver, you have to arrange matters so that the FSK input is grounded on mark and open on space. This is a little different from what you may have been used to. If you own the ST-5 terminal unit made by HAL, for example, or its big brother, the ST-6, you can't just connect its FSK output to the FSK input on the TS-820S. The reason is that the HAL units provide negative and positive voltages at the FSK output—about −12 volts on mark and +12 on space. This is an excellent method for keying most transmitters, but don't try it on the TS-820S. Such voltages will confuse the diode circuits Kenwood uses to shift frequencies.

The obvious solution is to insert a sensitive relay in your RTTY closed-loop circuit and use its contacts to key the transceiver. This is what I did, at first, using a small encapsulated relay I had bought from Poly Paks. It worked fine, except that it didn't seem quite "state of the art," and also it made the required CW identification a little awkward. (Since I was no longer using my ST-5 to provide keying voltages, I couldn't use its CW ID capability.) What you end up doing is inserting a hand key in series with the relay contacts. Just remember to close the shorting lever on the key after you've completed your ID. I forgot several times and ended up transmitting a fine unmodulated carrier, but no RTTY.

There had to be a better way, and there was. If I have learned anything in fifteen years of ham radio, it's that the best way to get help with a problem is to "talk it up"—preferably on the air. That's what I did. My solution came from Gordy WB9TGB, who had had the same problem. He passed along a simple two-transistor circuit which he, in turn, had gotten from Mel WØRV.

Fig. 1 shows what is involved. You need two NPN switching transistors (2N2222 or equivalent), a couple of resistors, and a scrap of perfboard. The 12 volts dc can easily be "stolen" from your terminal unit. Note that you get your CW identification by grounding the base of the second transistor—and you don't have to remember to close any shorting lever! I built my unit outboard, but it shouldn't be too hard to squeeze it into the cabinet of your terminal unit, unless you are very cramped for space.

If you use audio frequency shift keying (AFSK), of course, none of this applies to you. All you have to do is feed your audio tones into the phone patch "in" jack on the rear wall of the cabinet. Your problem then will be quite different. Since you will be transmitting lower sideband (LSB), you won't be able to use that beautiful sharp CW filter. There is a modification to get around this problem, made available by the Dovetron Corporation, but it involves several internal wiring changes in the TS-820S, and you may not want to do that. There's no reason why you should. With this solid state relay, going the FSK route is easy. ■

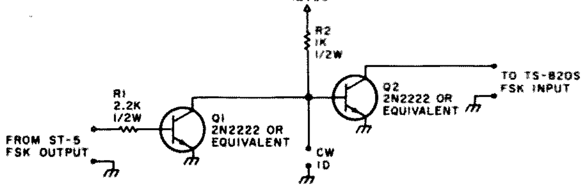

Fig. 1. An FSK relay for the TS-820S.

Einstein Was Wrong!

—this story has a Mobius twist

To quote the inspiring words of that highly-placed military official in 1776, "You can't make an omelet without you break eggs."

True. Remember that near-total blackout of the East Coast in 1965? And power-outages all over New England in February, 1978? And then there were those electrical failures around Peterborough, N.H. (home of *73 Magazine*), early this year.

Well, I'm sorry! Honest. I didn't *mean* to cause them. They were just by-products of a revolution—they happened because I was working on a revolutionary step forward in the field of ham radio which now can be revealed for the first time.

I'm not going to tell you who I am, yet. (That name, above, is a phoney, as must be obvious.) There are still too many soreheads around, and I will not risk exposing myself to the mobs until my Mobius-twist, All-purpose, Synergistic, Lumped-constant circuit, Hanger-hung, Folded dipole, Phase-velocity Transcalent-Transceive System (MASLHFPTS™) is bringing happiness into the average American home.

Background

Those blackouts were simply normal side effects of my genius. They were only because of little slips of memory, actually, for I am far from inexperienced in using electrical stuff.

Electrical stuff has always fascinated me. I remember my introduction to the field, in 1934, in Brooklyn, N.Y., when I was only 14. I hooked a crystal or something up to a radiator—I forget exactly how—and heard voices! And I couldn't have been older than 20 when I was able, most of the time, to find WJZ, WEAF, WOR, and some other stations on the family wireless!

As it happened, most of the years between those early triumphs in the thirties and the Big Blackout of the sixties were devoted to other hobbies in which I also excelled—I was Brooklyn basket-weaving champion in 1939—but I kept in touch with electrical stuff through the science section of *Time* and articles in *Reader's Digest*. (Not much of importance was going on in the radio field in those 30 years, anyway.)

But then, a few years before the East Coast incident, I ran across a book which has been guiding my research in sixteen areas ever since. With regard to science, a single little-known fact published in that book brought my interest in electrical stuff flooding back. I started work on my MASLHFPTS™ at once and went all out.

East Coast lights went all out, too! Joke! (Sorry.) What I had done was to hook up my Mark I transceiver (which utilized that little-known fact) to an antenna system consisting of all of the overhead lines in Greater New York with trackage of the N.Y. Central, Pennsylvania, and Boston and Maine railroads as the ground system. I was so eager to start operating that I didn't check out the circuits, but plugged in the power supply (the main generator of Con Edison) and blooey!

I had forgotten to fuse it!

Now look, I've already said I'm sorry. And please note: Each of the other outages, in 1978 and 1979, affected fewer people than the one before. If that's not progress, I don't know what you *want*!

Oh, yes, the little-known fact. I shall quote it exactly as it appears in the book—and you can check it out yourself.

*...electricity will pass through copper wire at the rate of two hundred and eighty-eight thousand miles in a second of time—a velocity greater than that of light.**

And on the very next page (p. 910), that vital information is augmented by reference to the "electric fluid" which gives rise to the

**The Circle Of Knowledge*, "Essential Facts of Everyday Interest in Nature, Geography, History, Travel, Government, Science, Invention, Education, Language, Literature, Fine Arts, Philosophy, Religion, Industry, Biography, Human Culture, and Universal Progress," Henry W. Ruotf, M.A., Litt.D., D.C.L., Editor-In-Chief. The Standard Publication Company, 1919.

appearance of lightning, and its velocity, which

. . . is not less than two hundred and fifty thousand miles per second.

Well, I ask you! With this knowledge of more rapid electricity than was recognized anywhere and of the existence of a fluid form of the stuff, what couldn't I do?

I won't bore you with all the difficulties of those early years of the development and microminiaturization of the Mark I MASLHFPTS™. I had to revise all of Einstein's formulas, too, of course, and gradually build up my knowledge of ether (which obviously does exist, after all; I have renamed it GLOP—for Global Lubrication Of Power), but I will share with you one discovery which will help you over any difficulties you may have in accepting the fact that relativity is a lot of bunk.

Einstein was secretly an associate of Bitten, Batten, Button, Distribution, and Ozymandias, that Madison Avenue firm which had the Waltham, Transworld, and Ivory accounts! He dreamed up his concepts of time, velocity, and size simply in order to sell watches, plane tickets, and the Large Family Size!

(Yeah, I thought that would shake you. I found out because I'm also an expert in advertising, mention of which leads me to the next phase of my research, the development of the Mark II MASLHFPTS™, the heart of which was my 1954, 18", black and white Philco TV set. I selected it because of that advertising slogan. You know, "You can be sure—if it's Philco.")

By early 1978, I had charted the lines of flux of the electric fluid at my QTH and had developed the Mobius-twist™ component of my antenna. This produced the well-known single-sided band which, naturally, provides constant resonance at all frequencies. I wanted to watch the Bruins playing hockey on Channel 38, but my Philco wasn't VHF—just UHF. (Or vice versa; I always get those two mixed up.) Anyway, in my mulling over this problem I suddenly remembered that 8 plus 9 plus 10 plus 11 adds up to 38! There was my answer!

Eagerly, I hooked up Channels 8, 9, 10, and 11 in series, attached my antenna, and plugged in. Blooey! I had barely glimpsed Yastrzemski, I think it was, poised for a slapshot, when the lights went out in Connecticut, Rhode Island, Massachusetts, Maine, New Hampshire, and Vermont.

I had forgotten to hook in my Adjustment Circuit Box!

Back to the drawing board, so to speak.

But good comes from everything, and as I rebuilt the blown parts, I was able to perfect a modification, the NN™ (No-Noise) attachment, which provides 100% effective rf suppression—no non-ionizing radiation on any band.

And so it was that by February of this year my Mark III MASLHFPTS™ was an almost-fully-tested QRN-free, all-mode transceiver, covering all bands from 12 Hertz (VVLF) to 300,000 GHz (Ultra SEHF). (It was possible to go below and above these frequencies, but under 12 Hertz I kept falling asleep for some reason, and over 300k GHz something kept happening to my eyeballs.)

Only one last step remained to prove the value and reliability of my Mobius twist and the Adjustment Circuit Box: turning it on. I flipped the GPMT switch (giga-pole, mega-throw) to Channel 4271 and powered it . . .

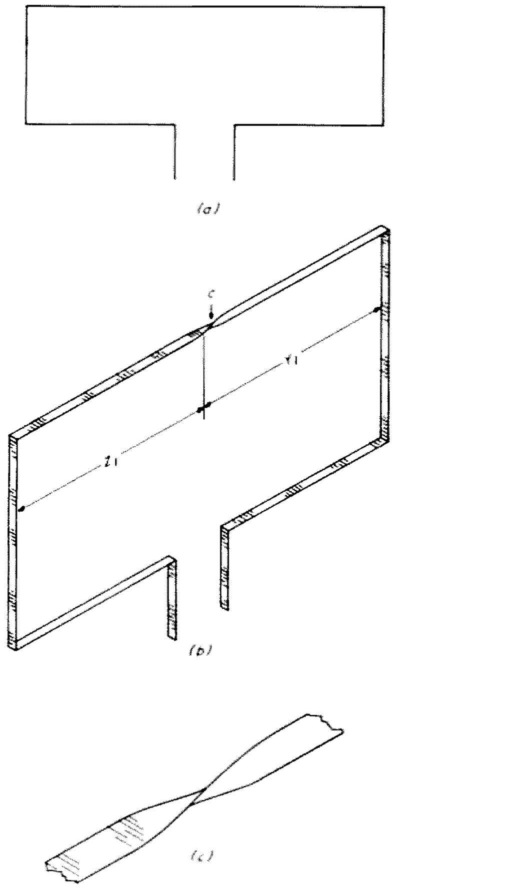

Fig. 1. (a) Schematic of Mobius-twist™, folded dipole, hanger-hung receive system. (b) Isometric presentation showing the location of the twist, with Z_1:Z: :Y_1:Y (see equation in text). (c) Detail of the twist.

Well, the blackout in Peterborough is hardly worth mentioning (no newspapers outside of some in N.H. and Boston did), but in the midst of some strange vibrations which made vision difficult, for about 72 seconds I watched the most incredible sight: The pictures coming in on my tube from the studios of the MGBC (Mars Galaxy Broadcasting Company) were in *color*! Yes, in *color*! I reached for the PTT unit to ask how come and blooey!

The blackout was nothing; the tragedy was the fire in my shack, for I had been forgetful again.

Construction

Nobody is perfect; there is this one component with which I am having difficulty and with the rebuilding of which I am going to ask your help. We'll get to it. But first, let's cover the *obvious* construction—the OB construction, I call it. (The other is the ŌB construction.)

Fig. 1 shows the basic receive system. So long as the total length of the Mobius strip is exactly L as in the following formula, it is not critical whether the unit of measure is the inch, chain, furlong, hand, or fathom. L can be made up of ells, even. Joke! (Sorry.) But L must = (300,000 GHz − 12 Hertz)/X(Z−Y), where X is the altitude of your QTH and Z and Y are its latitude and longitude, respectively. (If your shack is in Death Valley or elsewhere below sea level, it is

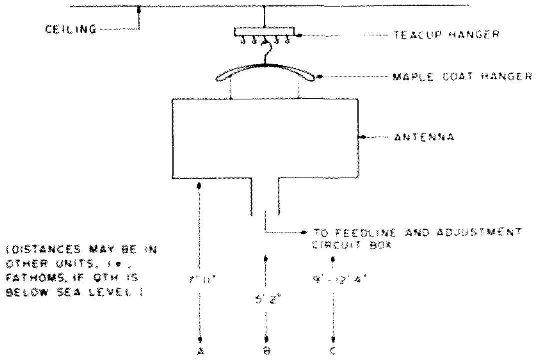

Fig. 2. Parts placement for the antenna array, and linear relationships to ambient resistances, resonances, and other wave influences. A—walnut bookcase; B—steel file drawers; C—bathroom pipes (find mean distance).

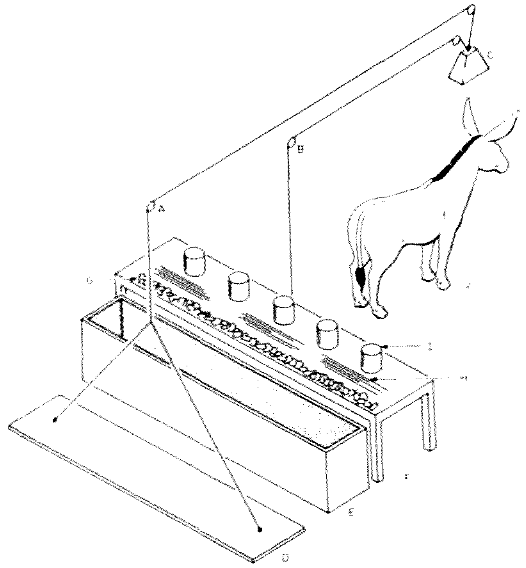

Fig. 3. Setup for the three steps. A—pulley system to jerk up cover (D) of Adjustment Circuit Box (E) when B, pulley system to weight (C) drops weight when mule (J) kicks over table (F) sending flying G—all components from your junk box, H—copper wires of assorted lengths, and I—pots of molten solder, into the perfboard-lined Box and onto the cover as it flies up and over. (Note: Weight C should be positioned to hit mule J on head to keep him calm until ready for the next setup.)

recommended that you use fathoms.)

Fig. 2 shows the critical distances between the Mobius twist and those elements which my experiments have shown provide the most favorable reception. Substitution of some materials is OK. The bookcase, for example, may be made of ebony, balsa, Hawaiian monkey pod, or Guamanian ifil instead of walnut, but the steel file drawers *must* contain from 36 to 42 back issues of *73 Magazine*; back issues of *Ham Radio* produce QRM, QRN, QSB, QSD, QTA, and 1-1 conditions.

The other important item is the Adjustment Circuit Box. It must measure exactly 2' x 2' x 8' inside dimensions, with all six interior surfaces covered with perfboard. Consult Fig. 3 and assemble all parts as shown.

Well, here is where your help is needed. You see, I was so anxious to get my transceiver operable that I plumb forgot to diagram or list, as I installed them, the diodes, triodes, tetrodes, pentodes, octodes, pigeontodes, resistors, transformers, inductors, solenoids, thyristors, shields, spark gaps, fuses, piezoelectric crystals, and switches!

Silly me!

But if you will do as I shall do, complete a setup as in Fig. 3, and follow the three simple steps listed below, one of us will *have* to come up with the internal electrical stuff for the Adjustment Circuit Box just as I had it arranged before the fire last February.

Step 1. Back a mule up to the setup and then annoy him.

2. Let the solder harden, plug in the circuit, and see if it works.

Step 3. Set everything back up again, and go back to Step 1.

Conclusion

There is one at every hamfest, and, Buster, I can hear you now, saying, "It won't work!" OM, you have forgotten the well-known fact that if a few thousand monkeys are provided with typewriters, sooner or later they will write the complete works of William Shakespeare.

All we have to do is to make monkeys out of ourselves by following the steps, and after some unknown number of mule-kicks in the future, that one last, essential component for the MASLHFPTS™ will be recreated.

And *then*, by golly, I'll be able to figure out why that MGBC program came in in color. ■

An 8-Bit DPDT Digital Switch

—many uses

Welcome to tristate.

Stirling M. Olberg W1SNN
19 Loretta Road
Waltham MA 02154

A couple of projects requiring the eight-bit output from an ASCII keyboard have been completed at W1SNN. These are an ASCII-to-Morse converter and an ASCII-to-Baudot translator.

A Southwest Technical Products KBD5 keyboard was purchased for the first of these two units, and later, when a television display and microcomputer from the same source were added to the station, the keyboard was included in the display framework. It is a considerable task to disconnect the keyboard each time the other units are used. Some might say why not use the microprocessor in the computer to eliminate these two peripherals. I thought of that, but also remembered the time and effort spent on them and decided that some means of switching the eight-bit output wouldn't be too much of a task.

By using tristate quadruple bus buffer gates with three-state outputs, as is often done in the microprocessor data input and output streams, it is very easy to reroute the eight-bit output from the keyboard to either of the aforementioned peripherals and to use the TV display to read what is being sent.

The bus buffers are 74125 and 74126 chips. The inputs of these devices are paralleled and fed into the eight-bit inputs of each of the external units. The ASCII-to-Morse unit does not require the full eight bits, and two of the buffers are unused in this requirement; however, they are all used in the other unit. Additional buffering was added to the bit stream output of the keyboard to reduce the load to the keyboard translator chip, which requires only one TTL load per bit.

Tristate buffers operate so that when the control input of each of the 74125 gates is high, the output is disabled; simultaneously, the 74126 outputs are low. The switch action therefore is completed. Control of the logic is from switch S1 which can be mounted near or on the keyboard.

As shown in the flow diagram, the data from the keyboard is directed into one or the other peripheral devices and into the television display. It may also be fed into the parallel input of the SWTP 6800. This operation provides "canned" sentences for retransmission recalled from the memory of the microprocessor.

There are many types of tristate chips available. I am sure that, by the time this is printed, it will be possible to find one LSI that will do all of the functions described. The ones used in this circuit are inexpensive and readily available from dealers found in the ads of this magazine.■

Get a Piece of The Rock

—a DXpedition to Gibraltar

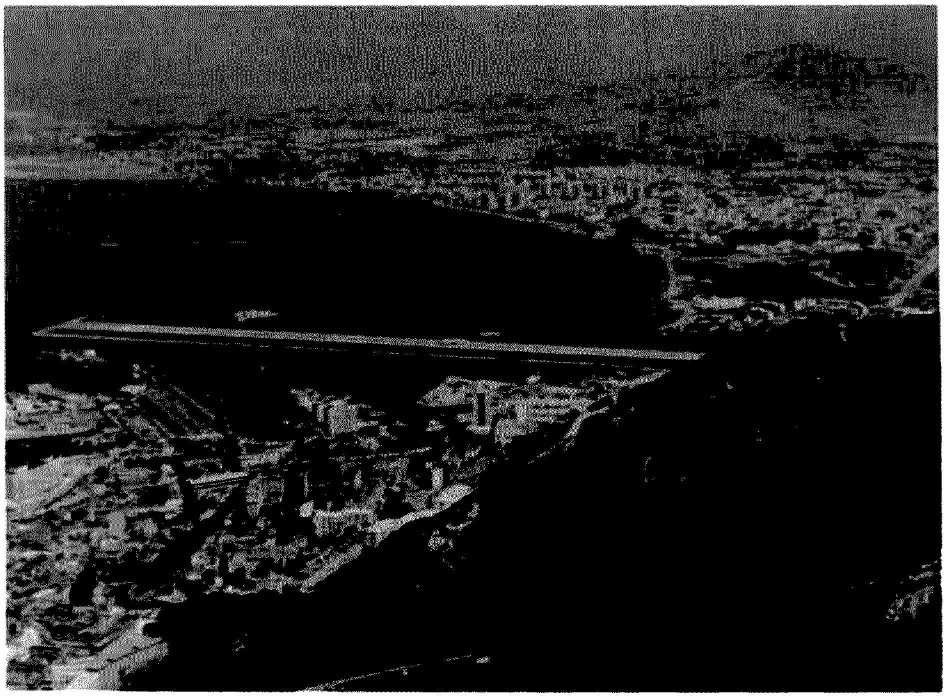
Slow careful CW, calling CQ, "de WDØEDX."

"This must be a fairly new ham," I thought. "I'll give him a new country." I called at 10 wpm, and back he came and said, "Where is Gibraltar?"

There I was, sitting in the shack of Jimmy Bruzon ZB2BL, which he very kindly loaned to me for a few days for my '78 ZB2CS expedition. In '73, I had operated from the Caleta Hotel on the east side of The Rock. In '75, I was on the west side of The Rock at the Montarik Hotel, and in '78, I was lucky enough to have Jimmy's quad to help things along.

Twenty meters was in fine shape in late July and the USA was roaring in. I slid up to 14.285 for some SSB operation. This time I was going to work a lot of Generals that I had not picked up before. One of the first was WA2PYI, who had just received his General and reported that I was his first SSB contact, his first ZB2, and his first DX. At the other extreme, W1HZV confided that in 46 years on the air, I was his first ZB2.

SSB signals from the USA are fantastic in Gibraltar. US hams are excellent operators. On a stand-by, the QRM was fierce, but when I went back to one station, everyone else was silent. The only times there were any problems with several talking at once were when conditions were marginal and some probably were not hearing me well enough to know who I was trying to work. A number of 6s and 7s came through well, and even KL7HRN was readable through the east coast curtain. It is possible, with a little concentration, to pick up 4 or 5 calls in a pileup and then work all of those before picking up more. This was not during a contest, but I was trying to work contest-style to contact as many as possible. About 50% of the people I worked said I was a new country for them. This is a real pleasure for one who is accustomed to being a run-of-the-mill W9 on the other end of the pileups.



This view shows the town of Gibraltar, left, the airstrip, center, and the town of La Linea, Spain, beyond the airstrip.

Gibraltar is probably best known through the efforts of The Prudential Insurance Company and its slogan, "Get a Piece of The Rock." The model that Prudential uses in TV advertising is only about one-tenth of The Rock. The Rock actually extends about 3 miles to the right of the model as shown and the airstrip is at the foot of the model just to the left. The concrete runway has one end in the Bay of Gibraltar and the other end in the Mediterranean. After considerable air travel, this is

the only place where I ever saw a jet airliner put the jets in reverse while still 100 feet off the runway. I found out that the British Trident is one of the few airliners to be able to handle this condition.

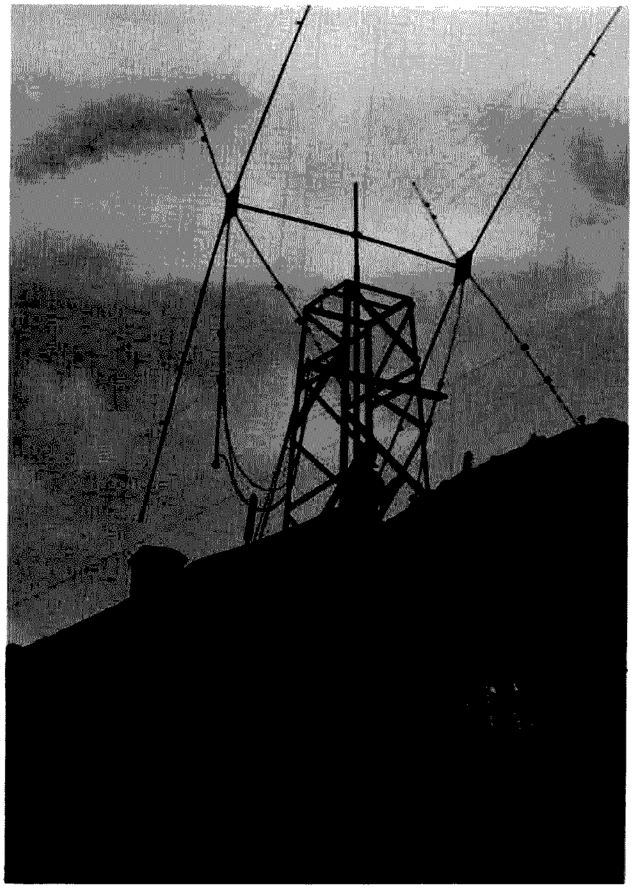
On one trip to The Rock I made the mistake of taking in three cardboard cartons of radio gear. This was impounded by customs, and I had to wait 24 hours while officialdom made a ruling that I could get it back. If your gear is in a suitcase, there is no problem.

A license is not hard to get. The postmaster is in charge of such things, and a letter in advance with a copy of your personal license is enough. The fee is about $2. Almost 200 ZB2 calls have been issued, but most of them are British servicemen long gone to other duties, and a scattering of occasional visitors like myself who show up once every few years. The most recent visitor, a few months ahead of me, was Ken Palmer K2FJ/ZB2C, who ran a Gibraltar expedition in February '78. An important consideration to remember is that Gibraltar power is 50 Hz and 250 volts only.

Parts and accessories are hard to come by. Almost everything must be ordered and shipped in; duty, plus the shipping costs, all add to the expense. Jimmy ZB2BL is a TV service man and is able to get ahold of some electronic parts, but there are needed items which normally are not in TV stock. There is a hi-fi store on Main Street across from the Montarik Hotel which has Kenwood 520 and 820 transceivers for sale at considerably higher prices than here in the USA. If one didn't mind the extra expense, it would be possible to fly in and buy equipment locally to get on the air.

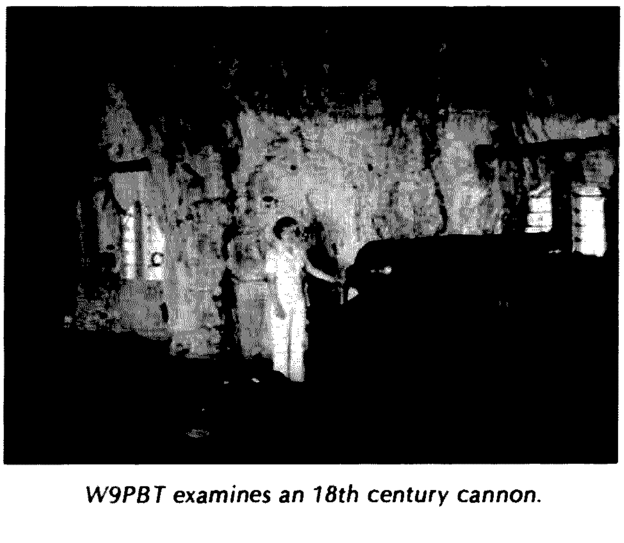
Gibraltar's people are bilingual. The schools and all public business are officially conducted in English. Everyone speaks Spanish most of the time, however. The well-educated people speak both quite well. With American or British visitors, they speak English all the time. They switch back and forth when speaking to each other. The reason, they told me, is that some ideas are expressed better in one language and other ideas better in the other.

Gibraltar is isolated; it is a peninsula connected to Spain. There is a road, but the gates were closed by the Spanish government ten years ago and no one is allowed to pass through.

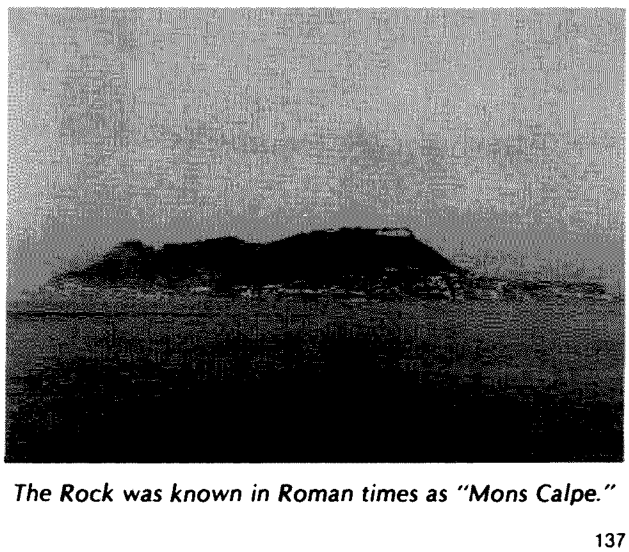


This is the ZB2BL triband quad with its owner.

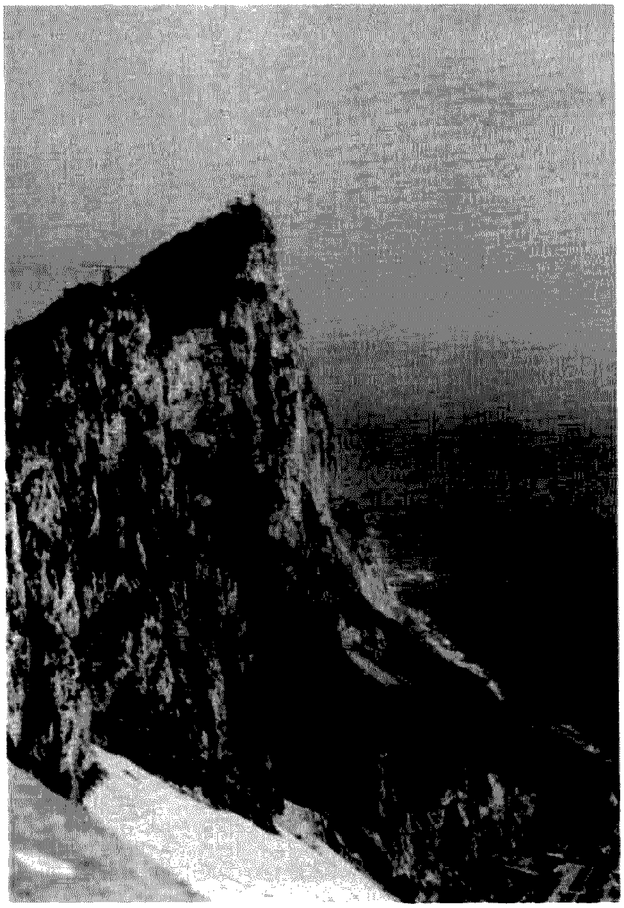
Many residents of The Rock have relatives and friends in Spain. In order to visit they must take the boat across to Tangier and then back to Algeciras. This means a considerable cost in money and time to make what should be a simple, inexpensive, short trip. Spain wants control of The Rock. The closing of the gates is part of a move to get the British to leave. The citizens of Gibraltar much prefer English rule, and many of them are of British descent.



W9PBT examines an 18th century cannon.



The Rock was known in Roman times as "Mons Calpe."



The eastern face of The Rock.

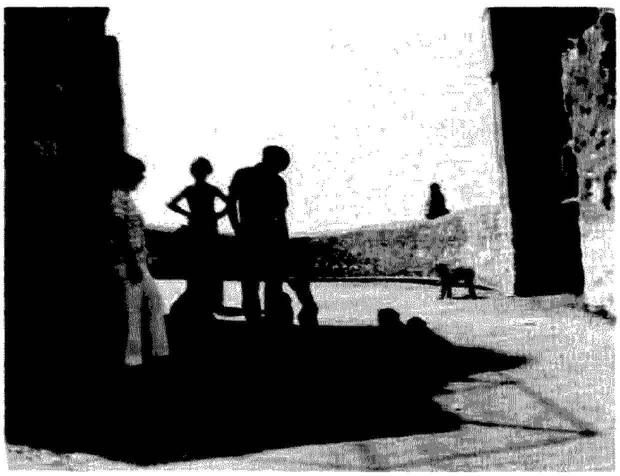
The only time the gates are opened is on the rare occasion when a critically-sick person is taken through to the Gibraltar hospital. There is no commercial or tourist traffic allowed.

The Rock apes are known far and wide. These are really monkeys in terms of size, but since they naturally do not have tails, they are classified as apes. With the rise of human population, they are concentrated in one area known as the apes' den. The British Army looks after them and supplies food and medical attention. They can be tricky rascals, stealing cameras and purses, and at times they bite. It is best to be careful when around them!

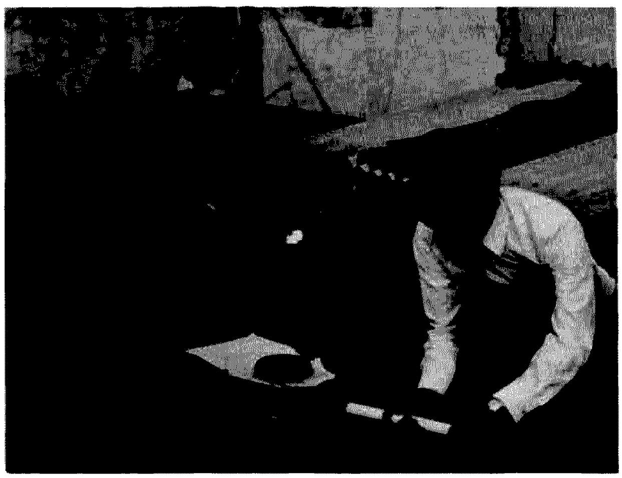
There are plenty of good hotels and restaurants available. The population is about 18,000 and there are stores, bars, banks, and all the normal activities of any medium-sized town. Ham radio from Gibraltar is quite interesting, as one is in demand and a pileup starts in a hurry. About half the people I worked wanted a card for a new country. A transceiver and a dipole are plenty. There are several places to set up—in hotels, up on The Rock, or even in a rented car for mobile operation. From the south end of The Rock at Europa Point one has a clear shot in all directions.

One place which might look good is the top of The Rock, but it is no good for HF work. Apparently due to the almost vertical cliffs falling away on two sides, the angle of radiation is not useful for DX. It has been tried with very poor results, while at lower levels, signals were strong both coming and going. The top is good for VHF. As a matter of fact, the Gibraltar Amateur Radio Club was planning a 50.3 MHz beacon to be placed in operation from the top of The Rock before the end of 1978. An earlier beacon on 50 MHz was heard over much of the eastern part of the USA in early 1978, and all the reports from this success have encouraged a better effort.

My wife, Milly, had a good time shopping in the Gibraltar stores for things to bring home to our four daughters and two grandsons. After three trips to Gibraltar, I have two very good friends there, and this time we had even more social get-togethers as my wife came, too, and we saw more of the Gibraltar wives. We had dinner with Jimmy ZB2BL and Tere Bruzon, and Cecil ZB2CF and Lourdis McEwen. On my earlier visits I had met both of these ladies and formed the opinion that they did not speak much English. It turned out that they were a little shy, and I very much admire their bilingual abilities. If I could speak Spanish half as well as all of them speak English, I would be quite pleased. As it was, I managed to add a few more words to my Spanish vocabulary.



Milly Williams W9PBT/ZB2 and a French tourist watch a British Army keeper of The Rock apes.



Cecil McEwen ZB2CF and Jimmy Bruzon ZB2BL are hunting for a defect in a loading coil.

Jimmy Bruzon ZB2BL is without a doubt the leading amateur on The Rock. He operates the DX bands and OSCAR. He also is in charge of ZB2VHF, the beacon operation, and a real pusher behind ZB2BU, the Gibraltar Amateur Radio Club. The club has several members who are working towards licenses and a very neat new club meeting room with a Kenwood 520 about to be installed. Jimmy earns his money as a TV service man, and several people told me he is the best.

Cecil "Mac" McEwen ZB2CF has given many happy 5BDXCC hunters a contact on 75. He also works various other bands at times. He recently moved into better living quarters, but has some antenna restrictions. He hopes to get something better than his present vertical and loading coil in the air.

This is the proposed site for the new 50.3 MHz beacon, atop The Rock in abandoned fortifications.

I now have 46 countries and 35 states worked from ZB2, so I will be going again in the next couple of years to finish off a DXCC and WAS from The Rock.

For those who would like to give it a try from Gibraltar, I will be glad to offer suggestions and advice and answer questions. It's an easy place to get to and to become the center of a real pileup. Now I'm planning Gibraltar IV. ■

Easy-to-Build 220 Transverter

—simple hookup to any synthesized 2m rig

Frank Kalmus WA7SPR
President, R.F. Power Labs, Inc.
11013—118th Place N.E.
Kirkland WA 98033

One day I took a good look at my 2-meter gear and found that I had an unusual amount of 2-meter equipment but only one Midland 13-509 for 220 MHz. This disturbed me somewhat, because 220 MHz is coming up strong in this country. Having only one piece of 220-MHz equipment to choose from made me wish that there was some way I could convert my excess 2-meter gear to 220 MHz, so that I could go on all of the channels without having to buy additional, expensive, synthesized 220 equipment.

Well, it did not take me very long before I came up with a block diagram showing how I could get around the purchase of a 220-MHz synthesizer by using my 2-meter synthesizer instead, and making it receive and transmit on 220 without the external LO inputs required by many transverters. No connections are needed from the transverter to the 2-meter transceiver except for a piece of 50-Ohm coaxial cable from the transceiver antenna connector to the transverter input connector. See Fig. 1. The transverter runs off +12 volts at about 300 mA for the 1-Watt model, and about 2 Amps for the 10-Watt version.

I connected my prototype to the accessory socket of the Multi-2700. The antenna connects to the output of the transverter. That's it! All of the switching and converting is done automatically by the transverter. The decimal readout remains as is, and the MHz are converted as follows: 145 MHz is 222 MHz, 146 MHz is 223 MHz, and 147 MHz is 224 MHz. It's as simple as that!

If you want to go to 223.500-MHz simplex, you set your radio to 146.500 simplex and let the transverter do the rest. If you want to go to some repeater frequency, let's say 222.500 in, 224.100 MHz out, you simply set your 2-meter radio to the repeater output frequency (147.100 = 224.100), flick the transverter mode switch to Repeater, and bingo! You have an instant 1.6-MHz offset putting you on a repeater mode for all 220 repeaters.

You can work simplex, duplex, reverse, and listen at any repeater input frequency to find those hard-to-locate secret machines.

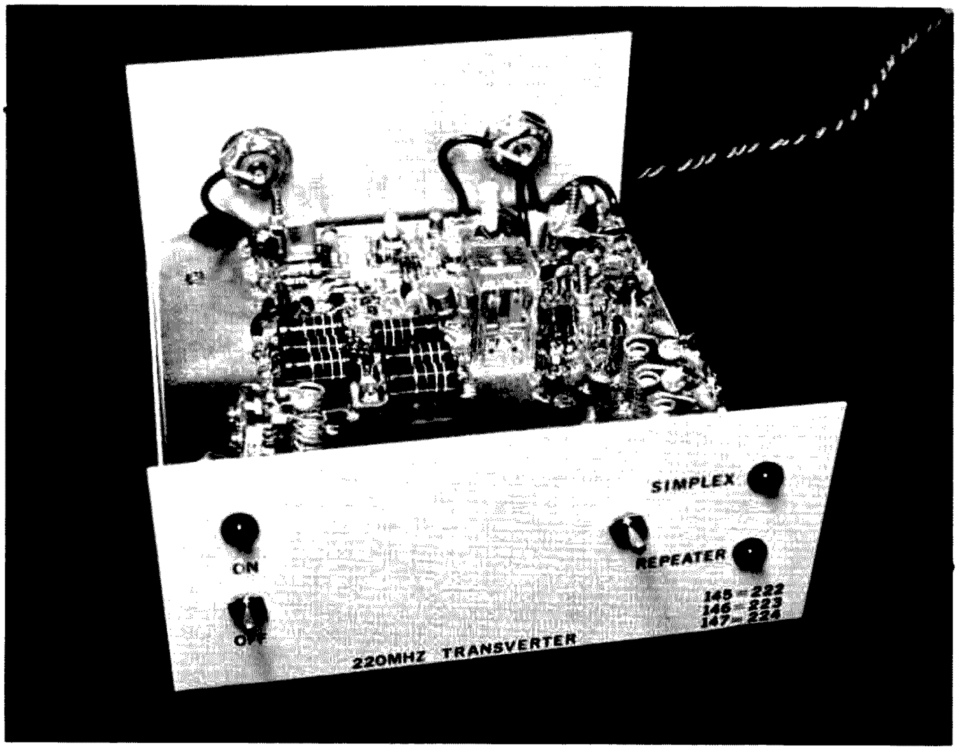


Photo A.

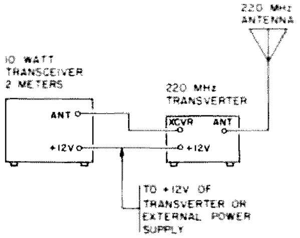

Fig. 1. Transverter connections.

Theory—How It Works

Fig. 2 shows in simple blocks the signal flow from and back into the antenna, and also from and back into the 2-meter transceiver. Fig. 3 is a complete schematic. The system is divided into two parts: the receiver and the transmitter.

Receiver: The 220-MHz signal received by your antenna is fed to a narrow bandpass filter with very low loss at 220 MHz, but high rejection at 146 MHz and all other frequencies located outside the 220-MHz band. This is required to keep strong 2-meter stations such as local repeaters from getting through the transverter and into the very sensitive 2-meter receiver. Also, the filter keeps local FM broadcast stations out of the front end of your transverter, which could cause possible intermodulation distortion.

The filtered 220-MHz signal goes through pins 6 and 5 of the T-R relay to the FET preamplifier stage. This extra stage of amplification was needed to reduce the noise figure of the transverter to about 2.5 dB instead of the 6-7 dB offered by the double-balanced mixer following it. Note that both the input and the output of Q11 (FET preamp) are tuned for good rejection and best noise figure. The gain of the preamp is about 12 to 15 dB, depending on the mood of the transistor that you happen to have in the circuit. The output is coupled directly to a double-balanced mixer consisting of D5 through D8 and T8-T9. Our 220-MHz amplified signal is now mixed with a 77.000-MHz LO from crystal oscillator Q8 through power-splitter T7, with the i-f fed to pin 9 of T-R relay K1. From here it travels to the transceiver connector, already converted to a new frequency of 223 − 77 = 146 MHz. The 2-meter transceiver connected to this terminal will eat this newly converted 223-MHz signal right up, just as if it had been 146 MHz!

Transmitter: This part proved to be much more difficult than the receiver because of the fact that we have a 10-Watt signal feeding a mixer capable of only 1 milliwatt of power conversion. Also, the signal needed to be re-amplified to a point where it was again usable for reasonably distant communications; in this case, 1 Watt, or 10 Watts, as you prefer. You may decide that 1 Watt is sufficient to

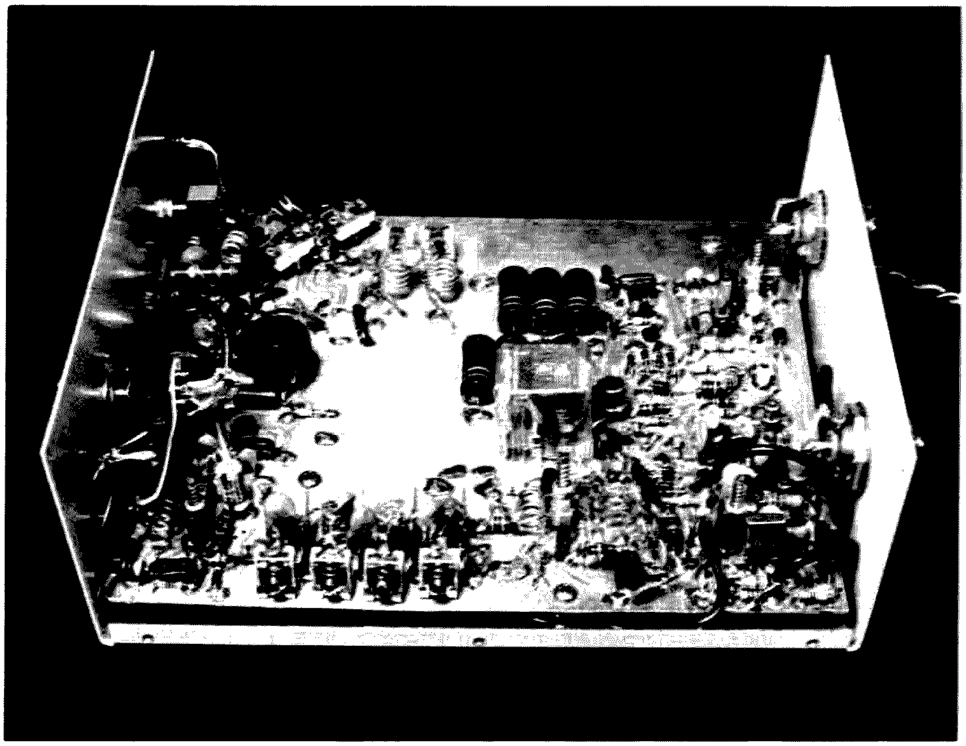

Photo B.

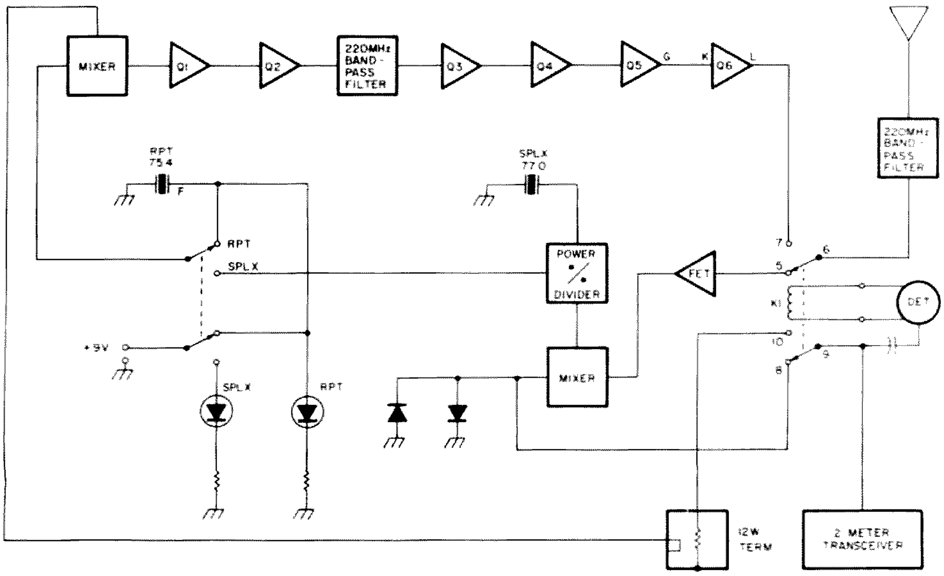

Fig. 2.

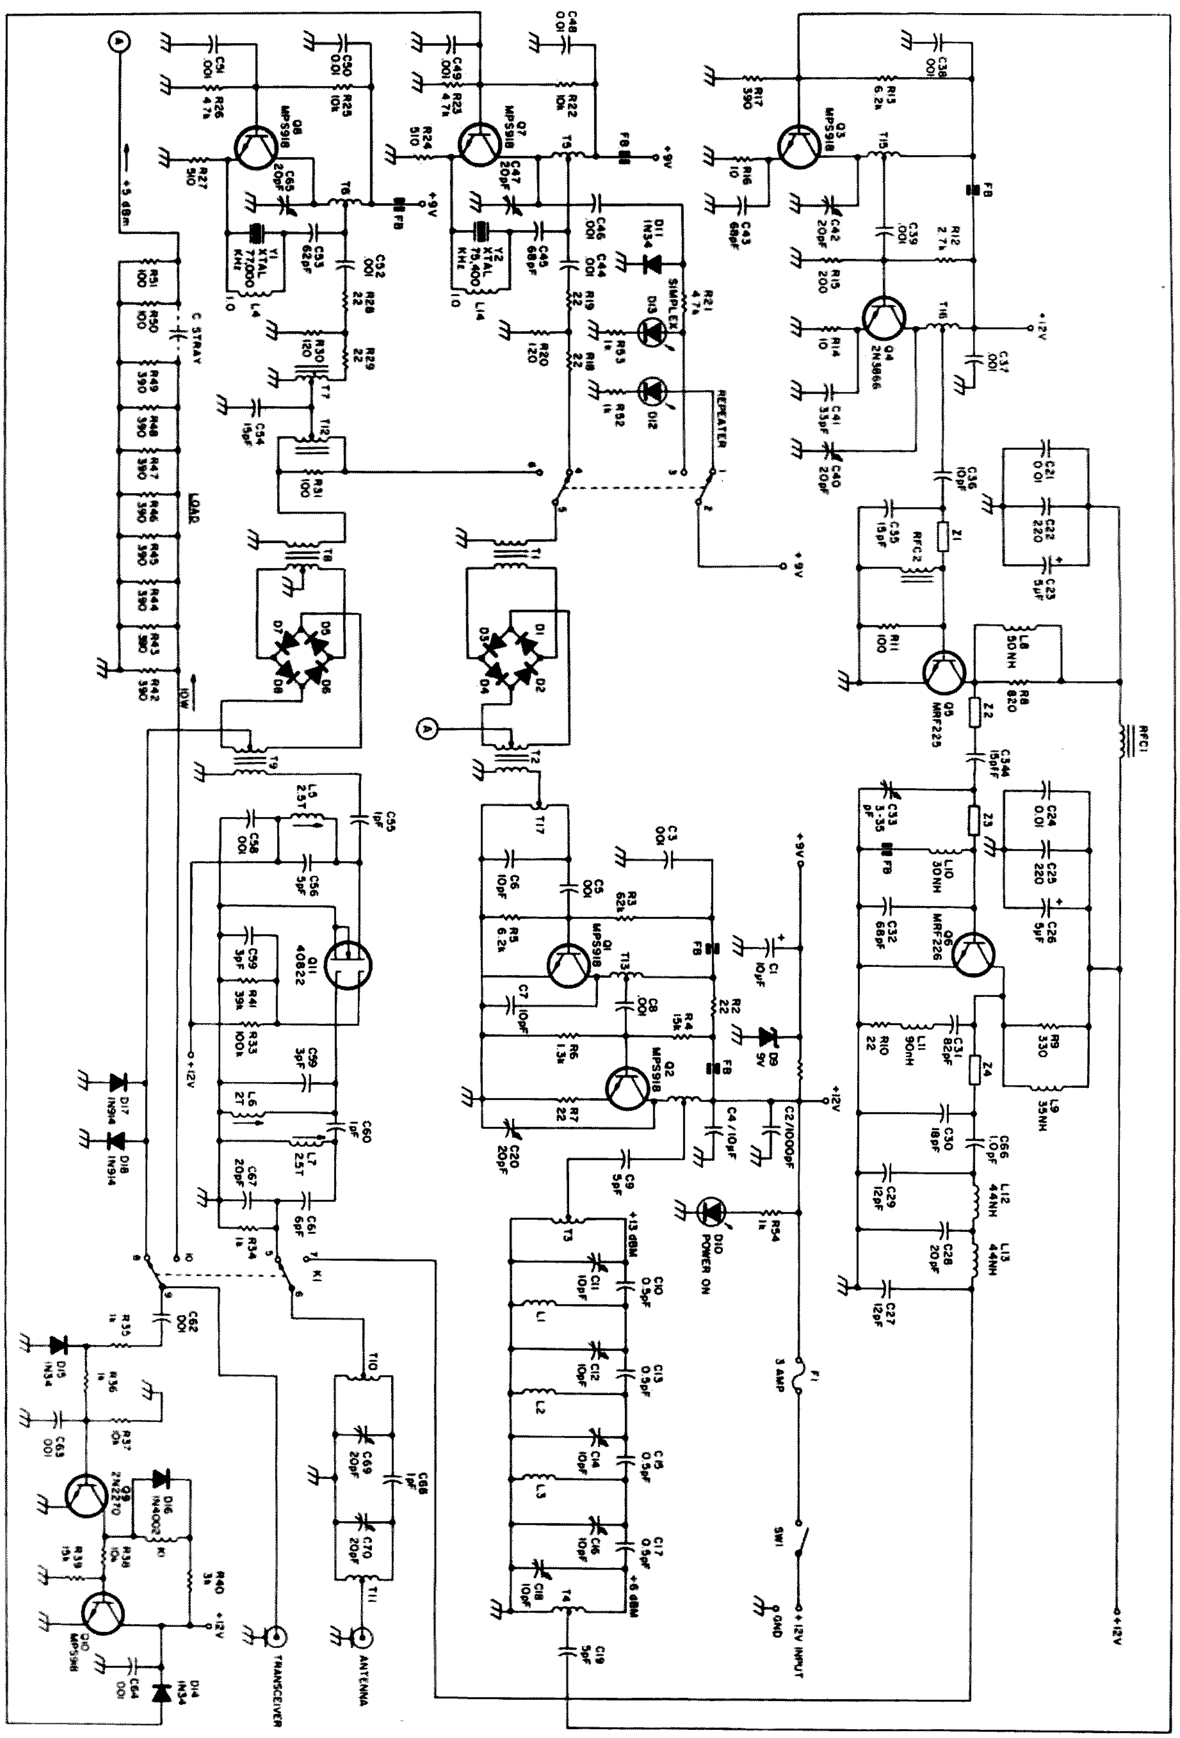

Fig. 3. Shielding beads are indicated by FB. Unless otherwise specified, resistors are in Ohms, capacitors in picofarads, and inductors in microhenrys.

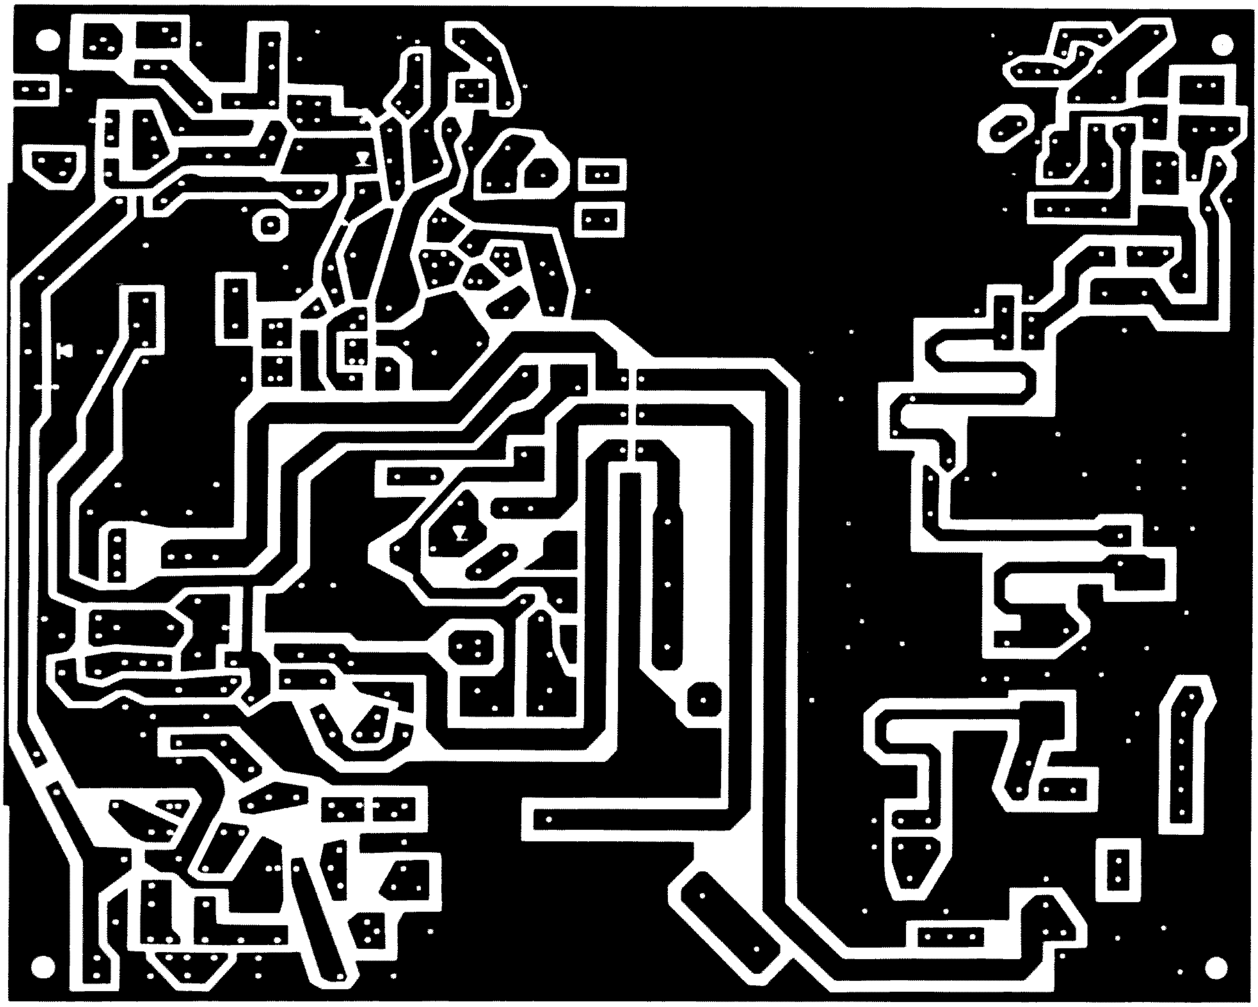

Fig. 4. Top of PC board.

get you where you want to go, or you may want to go all the way and stuff the PC board with all of the parts needed for a full 10-Watt output.

The board has been designed to make it a 10-Watt unit. For the 1-Watt selection, the last stage, Q6, is omitted and the C34 capacitor connects to pin 7 of K1 instead of to C27 and L13, as is shown in the schematic.

When transmitting, let's say on 223.500-MHz simplex, your transceiver is set to 146.500-MHz simplex and produces anywhere from 2-12 Watts. The rf power is received through the transverter input connector and is routed to pin 9 of K1. The signal is fed through the relay (pin 10) to a dummy load capable of absorbing the energy. The rf detector, D15, connected to the transceiver input signal, causes Q9 to conduct, thus pulling in K1 and consequently feeding the signal to pin 10 of K1.

Two 100-Ohm resistors in parallel give us 50 Ohms, creating sufficient stray coupling to sample about 1 milliwatt of rf energy from the dummy load. This small, 1 mW at 146.500 MHz, is fed to T2 of a double-balanced mixer (D1 through D4). With the mode switch in the simplex position on the transverter, we have selected the 77.000-MHz oscillator fed from the T8 power-splitter. The mixer upconverts the signal to 223.500 MHz at the base of Q1. Two stages of selective frequency amplification boost the small signal (about 200 microwatts) back up to about 20 mW at the input of our highly selective bandpass filter, starting with C9 and ending with C19.

This filter was necessary, not to make the transverter work, but merely to satisfy the FCC spurious-radiation specification requirement. Tuning is very delicate and could mean the difference between getting the system to work or not getting it to work. Power output of the filter should be around 1 to 5 milliwatts. The output of the filter drives Q3 and then Q4. Both stages boost the newly-converted signal up to 100 milliwatts before entering a two-stage microstrip-designed 1- or 10-Watt amplifier board. Tuning is not very critical, but care must be exercised when installing the parts. Make sure all leads are as short as possible, and that only non-inductive parts are used. Remember, this project is to be used on 220 MHz, not on 80 or 20 meters. It may sound picky, but it's not; 220 MHz is a far cry from HF, and what may work at 20 MHz will not work on 220 MHz—take my word for it. You may wind up settling for ½ Watt instead of 10 Watts, and you will be wondering why.

The output of the final

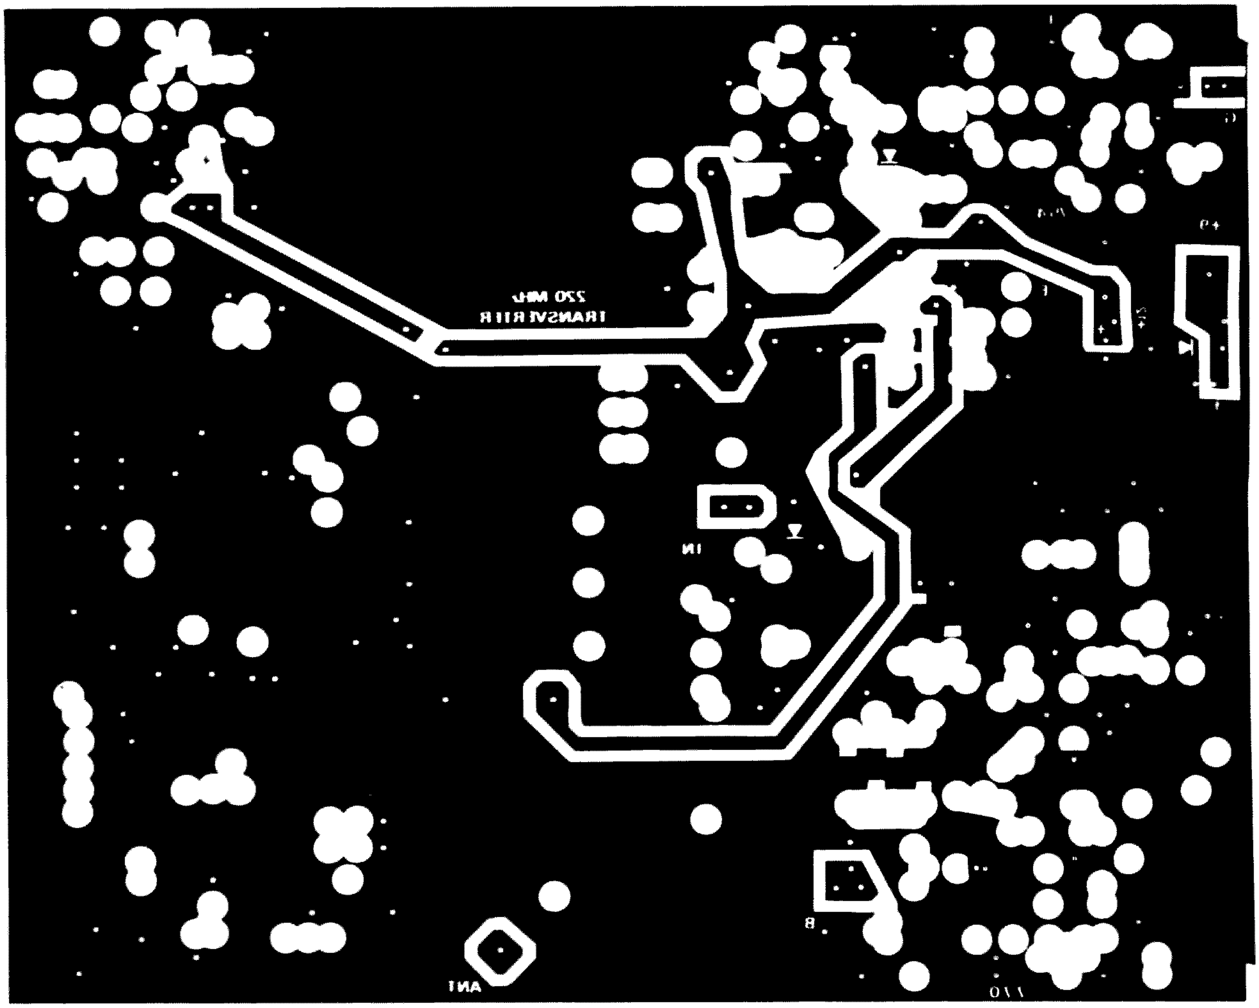

Fig. 5. Bottom of PC board.

power amplifier feeds pin 7 of K1 through pin 6 to the bandpass antenna filter and out to the coax, in the form of a very clean and respectable 223.500-MHz signal. How about that!

Should you want to work the 220 repeaters, all you have to do is to put your transverter mode switch to repeater, and forget it. The transverter automatically will select the 75.400-MHz oscillator, Q7, and connect it to the T1 mixer as before, except that the output frequency will now be 1.6 MHz lower than for simplex. The receive frequency will not be affected by this offset. It will still receive on the 77-MHz oscillator. While receiving on simplex, the 75.400-MHz LO is disabled through Q10 and D14, eliminating possible spurious responses created by the two oscillators beating. While transmitting, the 75.400-MHz LO is disabled only if the mode switch is in the simplex position. Both oscillators are powered by a 9-volt zener reference diode for good frequency stability. For extra precaution, one may want to put a diode in series with the 12-V lead for reverse-polarity protection.

One more note about the narrow bandpass filter. If properly tuned, the filter should be 4-MHz wide and pretty flat, because of later stages following the filter going into saturation amplification.

Construction

If you are going to make do with 1 Watt of power out, you will be making things a bit easier on yourself than does the ham who may want to go all the way up to the last stage of 10 Watts. The 10-Watt stage requires a little extra drilling and fitting to get the studded final power transistor in place. We will get into this a bit later.

The transverter was designed in such a way as to make it possible to assemble the entire unit on one PC board (double-sided) with only the LED lights, power switch, mode switch, and connectors to be wired after completion of the board. Foil patterns for the top and bottom of the board are shown in Figs. 4 and 5. Fig. 6 shows parts placement. I did, in fact, test and align the first unit outside the box, and later installed it into the box and completed the wiring of the final box within 20 minutes, including drilling the holes. An LMB box, no. CO-3, measuring 6″ × 7½″ × 2.75″ high, was found to be just the right size to fit the PC board with only 1/8″ of room left all around the box interior. No more extra room was needed because all of the wiring was located on the PC board. The panel LEDs, switches, and rear panel connectors did not require more than 1/8″ all around to sneak a wire through. The box also lends itself to

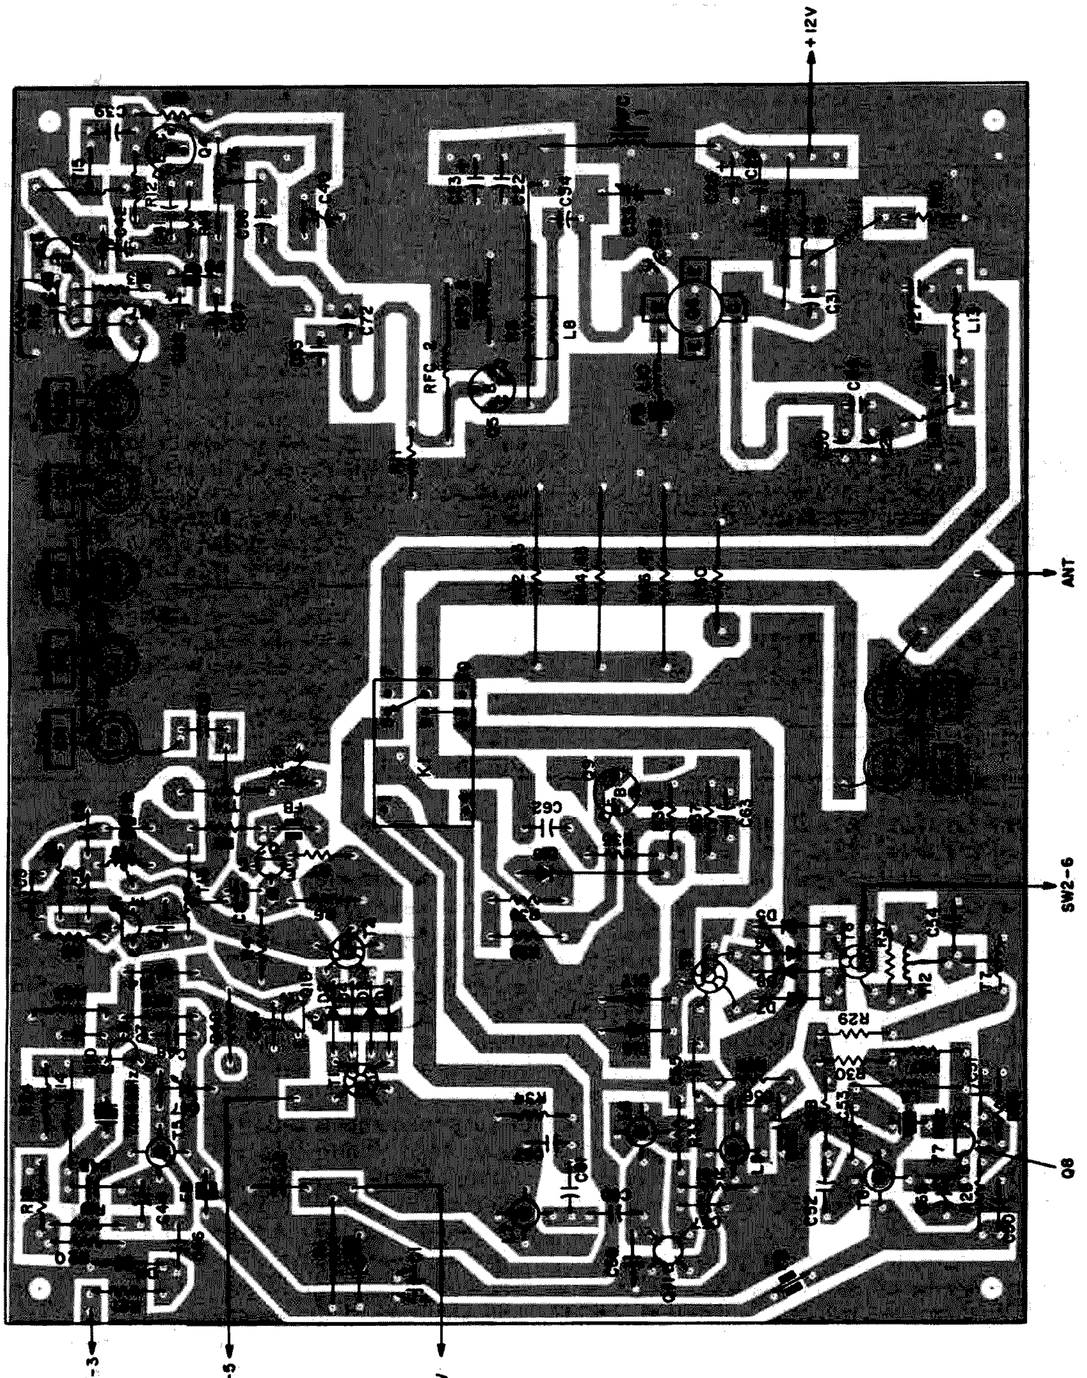

Fig. 6. Parts location.

this project very well because it has a removable top cover, enabling you to finish the wiring completely with all sides exposed. Tuning and testing will be made easy because of this. See Photo B.

The two switches and three LEDs located in the front panel take 1/4" holes, and the two UHF connectors in the rear panel can be the 5/8"-diameter type or the 4/40 mounting-screw type. They are spaced about 3½" apart and are set up about 1½" from the bottom of the cabinet, to clear the PC board. When mounting the connectors and the front-panel lights and switches, be careful to locate them in a place where they do not interfere with the components protruding from the PC board. RG-174/U minicoax is used for input and output connectors and also for the mode switch, SW2, controlling the two oscillators.

The ground braids of the three cables are connected together at the switch and are left free-hanging. The cables will be quite secure because all the connections make them very rigid. The three 1k resistors for the LEDs are connected directly to the LED terminals, and the other ends of the resistors are soldered straight to the PC ground. When soldering your components to the PC

board, take a little care not to push them all the way down to the ground plane; some components may have bare spots and could cause shorts across the top side of the PC board. Make sure your solder connections are good, and free from splashes. This will save you time when you get ready to fire it up. Details of filter construction are shown in Fig. 7.

The transparent rub-off lettering worked well for the marking of both front and rear panels. Make sure you put the following reminder on the front panel, as is shown in Photo A: 145=222 MHz; 146=223 MHz, and 147=224 MHz. This will keep you from guessing the new frequency after the project novelty has worn off and you can't remember the conversion formula.

If you are planning to put in the last amplifier stage for a full 10 W of output power, you will have to drill a 3/8" hole directly underneath the stud of the transistor. Place a piece of 1"x 2" aluminum over the stud before you put the screw back on it. It will act as a heat sink, necessary to keep the final cooled. You may want to add more fins to make the radiating surface larger, if you feel the transistor is getting too hot. Make sure your heat sink does not make contact with any part of the PC board that is not ground; it may cause short circuits. The PC board should be raised at least 1/4" from the deck by using four 1/4" metal spacers. This will provide sufficient clearance, and furnish a good solid ground to the chassis. The MRF225 driver transistor must also be equipped with a top-hat heat dissipator.

Alignment and Adjustment

After careful inspection to make sure that all of the correct parts have been installed in the proper places, you may proceed with the first step of the checkout procedure. All of the wires should be connected, including the lights, switches, and connectors. Should there be any serious problems, you will not have to dismantle the whole thing again. If all basic tests are positive, you may align the transverter "into the ball park," and then remove the panel gadgets and final-assemble the unit.

Last touch-up is usually easy. Take it one step at a time. With 12 volts applied to the red wire and the black wire grounded, flip the power switch to on. The "on" LED should light and also one of the mode lights, depending upon which position the mode switch is in. Flip the mode switch to the other position and the other LED should light. The total current drawn from your 12-volt supply is between 150-220 mA if all is normal.

Receiver and Antenna Filter

Tune in a known repeater on 220 MHz and hook up the transverter as in Fig. 1. Set the power switch to on and the mode switch either to simplex or repeater operation—it does not matter in the receive mode. Set the 2-meter transceiver to the frequency corresponding to the converted frequency as described earlier. For instance, if you have a busy 220-MHz repeater on 224.100 MHz, set your 2-meter transceiver to 147.100 MHz and tune C69, C70, L5, L6, and L7 for maximum S-meter reading on the 2-meter transceiver. Should you have problems, it may be that the oscillator (77,000 kHz) is not doing its thing. Usually, a few turns in either direction with the variable capacitor, C65, will get it going. All you need to do then is to put it on frequency by tuning C65 to a point that will show zero or midscale on a 2-meter discriminator meter. One more time, tune all of the previously-mentioned tuning elements for maximum signal strength. This completes the alignment of the antenna bandpass filter and also the FET preamp. Your sen-

(For parts, PC board, etc., contact Frank Kalmus WA7SPR, 7016 NE 138th Street, Kirkland WA 98033.)

sitivity should be good—in the neighborhood of .15 uV, or so, even if your 2-meter radio is not that great. Remember, the transverter FET preamplifier is now your front end, and will set the noise figure and sensitivity unless your 2-meter radio is really bad.

Transmitter

If you possibly can do it, get ahold of any power meter capable of measuring a few milliwatts, like an H-P 430 (real cheap), and disconnect the center tap of T2. Connect a 50-Ohm resistor to ground from the end of the wire connecting to the T2 c-t. You now can fire up your transceiver in the low-power position. You should measure no more than 1 milliwatt, or so. In the 10-Watt position, you will measure 7-10 milliwatts. This is fine. If you do not get these readings, it may be necessary to change the coupling of the two 100-Ohm resistors, R50 and R51, to get more or less power sampled from the dummy load.

Once you satisfy yourself that you have sufficient drive for the mixer (consisting of T1 and T2 with the quad diode), you can proceed to the LO circuit, Q7. With the mode switch in the repeater position, the 75.400-MHz oscillator is selected. We must make sure the oscillator is working properly before we can continue. A frequency counter will help a lot—or a spectrum analyzer. (The latter is mentioned for reference only, realizing that the average ham can't afford that luxury.)

Connect the counter to R18 or pin 4 of the mode switch. Adjust C47 for a frequency reading of 75.400 kHz. You may now reconnect the c-t wire of T2 previously disconnected. Disconnect the 5-pF capacitor, C19, from T4 and measure power into an rf meter connected to this point, or into a spectrum analyzer. Tune C20, C11, C12, C14, C16, and C18 until you get some power output from the narrow bandpass filter. This is the hardest part of the tuning, and it may take several repeated efforts to get the filter to pass some rf. It is a very touchy filter, and although all other circuits are working, it might appear as if nothing was working at all. The filter can block all signals if not tuned correctly. If in doubt, disconnect the filter and bypass it to see if the 220-MHz signal is present after all of the mixing and amplification from the previous stages. If so, connect all back as before, and continue tuning the filter until you get some response. It should be possible to get 5-MHz bandpass from the filter, with very steep skirts.

The reason for the sharp filter is to reject the closely-located spurious frequencies caused by the mixer third harmonic ($3 \times 75.4 = 226.2$ MHz) and the frequency we want to process. Careful tuning will get the spurs down 60 dB. A spectrum analyzer is again the ideal toy to do it with. If all is done right, you should measure +6 dBm of 220-MHz signal at the output of the filter. Reconnect R19 and tune C42, C40, and C33 for maximum power output at the antenna terminal of your transverter. It should be about 1 Watt. If you want to go to 10 Watts and you have installed all of the necessary parts, no tuning is required. The final amplifier is somewhat broadbanded (about 10 MHz wide) and should produce about 60% efficiency when driven with 1 Watt and 12.5 volts. The output transistor is open- and short-circuit-protected for all load phase angles up to 15 V of dc input. Total current drawn by the transverter is 300-400 mA for 1-Watt output models, and 1.8 to 2 Amps for 10-Watt models. Harmonics and spurs on the prototype and first production unit were greater than 60 dB down.

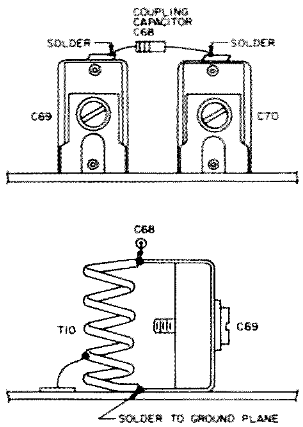

Fig. 7. Construction technique—2-section antenna filter and 5-section spurious filter.

After all checks out OK, you may proceed with the final assembly into the cabinet. Remove all lights, switches, and connectors and set the PC board inside the chassis with the crystal oscillators toward the rear of the cabinet. Mark the four mounting holes and drill them. Mount the PC board and string all of the cables through the cracks between the cabinet and the board for final wiring. You should not have to do much touching up after the final mounting process.

Putting the Transverter On The Air

After all circuits have been checked out and are working, the best way to tell what kind of a job you have done is to actually put the monster on the air and let the critical ears of your fellow hams judge you. Do not tell them what you are testing—they may be biased one way or another. If you are experiencing problems with noise or funny squeals in your 2-meter radio, it is your transverter doing it. It can be eliminated by slowly tuning one or the other oscillator slug until it stops. It will be caused by one of your oscillators putting out spurs if its tuning is not right. All you need to do now is to tune your 2-meter transceiver to simplex and let the transverter do the rest. It will put you on simplex receive and transmit if your mode switch is in the simplex position. If you want to go on a 220 repeater, leave your 2-meter radio on simplex on the repeater output frequency, but put the mode switch to repeater, and you are instantly in repeater-mode operation. You are now capable of tuning in to as many possible combinations as your 2-meter rig permits. If you have a 12-channel radio, you will have 12 channels on 220. If you are lucky and own a synthesized 2-meter radio, you will be able to play with 800 or 1000 channels on 220 MHz. Have fun, friends! I am sure having me a ball with this transverter!

The parts list is complete. All parts are easily obtainable from any local electronics shop. Most parts should be junk-box items, except for the high quality caps and Schottky diodes. A PC board is available for $14.00 from WA7SPR if you do not want to tackle your own layout. The hard-to-find toroidal transformers also are available in a small kit for $4.50 (T1-T2-T7-T8-T9 and T12). All other parts are available from the same source, should you have difficulties finding them in your area.

Total cost for the 1-Watt unit, assuming you have to buy everything, came out to about 65 bucks; it is $16 more for 10 Watts. If you have an average junk box, and wind your own coils, the 1-Watter should cost you no more than about $40. ■

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

BLACKSBURG VA
OCT 1-6

Two expanded workshops on 8080/8085/Z80 microcomputer design, microcomputer interfacing, software design, and digital electronics are being given by the editors of the popular Blacksburg books. Participants have the option of retaining the equipment used in these courses. Dates are October 1-6, 1979. For more information, contact Dr. Linda Leffei, C.E.C., VPI and SU, Blacksburg VA 24061, or phone (703)-961-5241).

HOUSTON TX
OCT 5-7

The Houston Area Amateurs will host the ARRL West Gulf Division Convention on October 5-7, 1979, in Houston, Texas. For further information, contact Houston Ham Conventions, Inc., PO Box 79252, Houston TX 77024, or phone (713)-466-0518 or (713)-223-3161.

SIOUX FALLS SD
OCT 5-7

The '79 ARRL Dakota Division Convention will be held from October 5-7, 1979, at the Sioux Falls Airport Ramada Inn, located off Exit 81 on I-29, Sioux Falls, South Dakota. Featured will be technical and operating forums, a ladies' program, an ARRL forum, a large exhibit area, and a banquet. Prizes include an advance-registration prize of a DenTron GLA-1000 amplifier, a grand prize of a Kenwood TS-820S and a second grand prize of a Wilson System One™ antenna and WR-500 rotor. Registration is $15.00 ($16.00 after September 1) or $6.00 for the convention only ($7.00 after September 1). Talk-in on 146.16/.76. For further information and convention-rate hotel accommodations, write Sioux Falls Amateur Radio Club, Box 91, Sioux Falls SD 57101.

WARRINGTON PA
OCT 6

The Mt. Airy VHF Radio Club Inc., will hold its Hamarama '79 and Mid-Atlantic States VHF Conference on Saturday and Sunday, October 6-7, 1979. The conference will be held on Saturday, October 6, from 9:00 am to 5:00 pm at the Warrington Motor Lodge, Rte. 611, Warrington, Pennsylvania. Featured will be an all-day VHF program, a cocktail hour and get-together, and a buffet dinner. Registration is $3.00 in advance, or $4.00 at the door, which includes the flea market. The buffet dinner is $9.00. The flea market will be held on Sunday, October 7, from 8:00 am to 4:00 pm, rain or shine, at the Bucks County Drive-In Theatre, also on Rte. 611. Registration is $2.00 with tailgating $2.00 per space (bring your own table). Featured will be amateur radio equipment, electronic parts, surplus, and door prizes. Talk-in on 146.52 W3CCX. For information, write Ron Whitsee WA3AXV, Chairman, PO Box 353, Southampton PA 18966, or phone (215)-355-5730.

CORNWALL NY
OCT 6

The Orange County Amateur Radio Club will hold its annual auction on Saturday, October 6, 1979, at Munger Cottage, Cornwall, New York. Admission is $1.00 and includes a chance on a door prize. The auction begins at 1:00 pm and sellers should arrive at noon. Talk-in on .52. For further information, contact Bill Lazzaro N2CF, 11 Jefferson St., Highland Mills NY 10930.

TAYLOR MI
OCT 7

The third annual RADAR Hamfest and Swap 'n Shop will be held on Sunday, October 7, 1979, from 9:00 am until 3:00 pm at Kennedy High School, Northline Rd., Taylor, Michigan. Admission is $2.00. Featured will be computer displays, ham gear displays, door prizes, and food. Talk-in on .93/.33, .52/.52, and .99/.39. For information, write RADAR, Inc., PO Box 1023, Southgate MI 48195.

ROME GA
OCT 7

The Northwest Georgia Amateur Radio Club will hold its annual Rome Hamfest on October 7, 1979, at the Coosa Valley Fairgrounds, Rome, Georgia. Gates will open at 9:00 am. Talk-in on 146.34/.94 and 146.085/.685. For further information, contact WB4AEG, Box 274, Adairsville GA 30103.

BERRIEN SPRINGS MI
OCT 7

The Blossomland Amateur Radio Association will hold its fall Swap Shop on Sunday, October 7, 1979, at the Berrien County Youth Fairgrounds, north of Berrien Springs, Michigan, on US 31, beginning at 8:00 am. There will be commercial exhibits, prizes, refreshments, plenty of free parking, and display space. Space for self-contained campers, at $3.50 including electricity, is on the grounds. Talk-in on 146.22/.82. Advance tickets are $1.50; $2.00 at the gate. Eight-foot tables are $2.00 and are restricted to electronic items. For advance tickets and information, write Charles White, 1940 Union Ave., Benton Harbor MI 49022.

ROCK HILL SC
OCT 7

The York County Amateur Radio Society will hold its 28th annual hamfest on Sunday, October 7, 1979, starting at 8:00 am, at Joslin Park, Rock Hill, South Carolina. Registration is $2.75 each or 2 for $5.00 in advance, or $3.00 at the gate. The main prize is a Yaesu FT-901DM. A barbecue dinner is available at the park. Talk-in on 146.43/147.03 and 146.52. For more information, write York County Amateur Radio Society, Inc., PO Box 4141 CRS, Rock Hill SC 29730.

OTTAWA ONT CAN
OCT 12-14

The Radio Society of Ontario will hold its 11th annual convention at the Skyline Hotel, Ottawa, Ontario, Canada. On Friday evening, there will be a buffet and dance. On Saturday, there will be demonstrations, forums, technical sessions, a women's program, and a banquet and dance. On Sunday, there will be a flea market and delegates' meeting. For information, write PO Box 5076, Station F, Ottawa, Ontario, CAN K2C 3H3.

SYRACUSE NY
OCT 13

The Radio Amateurs of Greater Syracuse will hold their annual hamfest on October 13, 1979, from 9:00 am until 6:00 pm at the New York State Fairgrounds, located adjacent to I-690, 3 miles southeast of the New York State Thruway, Exit 39, one mile northwest of Syracuse, New York. For commercial exhibitors, a fee of $15.00 will include a booth with a display counter ten to fifteen feet in length or a table and two chairs. Included in the $15.00 fee will be two tickets to the hamfest. Accommodations are available at nearby motels or travel trailer and motor home space will be available on the grounds. Commercial exhibitors will be able to set up their displays Friday night from 7:30 to 10:00 pm or on Saturday morning from 7:30 to 9:00 am. For more information, contact Bob Edgett or Paul Dunn, exhibitor chairmen, c/o Radio Amateurs of Greater Syracuse, PO Box 88, Liverpool NY 13088.

ASHEVILLE NC
OCT 13

The Western Carolina Amateur Radio Society will hold its Asheville Autumnfest on Saturday, October 13, 1979, at the Asheville Civic Center, Asheville, North Carolina. There will be ample space for manufacturers, dealers, and the flea market, which will be in another part of the arena. A concession stand will be operated by the Civic Center. All manufacturers and dealers will have separate booths. And it will be possible to drive directly to your booth for unloading.

MEMPHIS TN
OCT 13-14

The Mid-South Amateur Radio Association and participating Memphis-area clubs will sponsor the Memphis Hamfest and Tennessee State ARRL Convention on October 13-14, 1979, at the Youth Building at the Mid-South Fairgrounds, Memphis, Tennessee. Featured will be forums, exhibits, a giant flea market, FCC exams, a hospitality party, and commercial and manufacturer exhibits. The display area will be open from 9:00 am to 4:00 pm on Saturday, and from 9:00 am to 2:30 pm on Sunday. Fifty trailer hookups are on the premises, which the Memphis Park Commission will rent for $5.00 per night. For further information, contact the Memphis Hamfest, PO Box 3845, Memphis TN 38103, or phone Clayton K4FZJ at (901)-274-4418.

BEAVER OK
OCT 14

The Beaver Hamfest will be held on October 14, 1979, at the Fairgrounds Building in Beaver

OK. Doors open at 8:00 am, with registration at 10:00 am. Tickets are $2.50 each. There will be a covered-dish luncheon, a short program at 1:30 pm, swap tables, and door prizes. Camper hookups are nearby and the event is airport-close. Talk-in on .01/.61 and .52. For details, contact Stella Shaw WB5VUN, Box 310, Beaver OK 73932, (405)-625-3368.

LIMA OH
OCT 14

The Northwest Ohio Amateur Radio Club will hold its annual hamfest on October 14, 1979, at the Allen County Fairgrounds, Lima, Ohio. Two large heated buildings will house the hamfest where tables will be available for $3.00 each. A flea market will be held outside for free. Advance tickets are $2.00 each. For information, send an SASE to NOARC, PO Box 211, Lima OH 45802.

WEST GHENT NY
OCT 14

The Northeastern States 160-Meter Amateur Radio Association will hold its annual election and banquet on Sunday, October 14, 1979, at Kozel's Restaurant, Rte. 9H, West Ghent, New York. There will be a flea market in the rear parking lot at 1:00 pm and a roast beef dinner at 5:00 pm. All hams and XYLs are welcome. For reservations and details, contact William Derby WA5IOD, Secretary/Treasurer, 14 Plain St., Medfield MA 02052.

ISLIP LI NY
OCT 14

The Long Island Mobile Amateur Radio Club, Inc., will hold its Hamfair '79 on Sunday, October 14, 1979, from 9:00 am until 4:00 pm at the Islip Speedway, Rte. 111 (Islip Ave.), one block south of Southern State Pkwy., Exit 43, or come south from the Long Island Expressway, Exit 56, Islip, Long Island, New York. There will be free parking, door prizes, and several contests. Admission is $1.50 (non-hams are free) and $3.00 per seller's space, which permits one person to enter. For information, call Hank Wener WB2ALW, nights, at (516)-484-4322, or Sid Grossman N2AOI, nights, at (516)-681-2194.

ANAHEIM CA
OCT 19-21

The ARRL Southwestern Division Convention will be held on October 19-21, 1979, at the Sheraton-Anaheim Hotel, located at Ball Rd. and I-5, Anaheim, California. The convention will begin on Friday evening with registration and exhibits from 4:00 pm until 9:00 pm. On Saturday, registration will begin at 8:00 am and exhibits and technical sessions will run from 9:00 am until 3:30 pm. FCC testing will continue until 3:30 pm also. The ARRL Forum will be held from 4:00 pm until 5:30 pm, with a no-host cocktail party being held until the 7:30 pm banquet. The Wouff Hong pageant will be held at 00:01 am PST on Sunday morning. At 9:00 am Sunday morning the various breakfasts will be held and the exhibits will again be open until noon. The pre-registration deadline is September 15, 1979. Advanced registration price, which includes complete program, banquet, exhibits, and technical sessions, is $17.00, and $19.00 at the door. The charge for the banquet only is $12.00, and for exhibits and technical sessions, the charge is $5.00, pre-registration; $6.00 at the door. The ladies' program and luncheon is $6.00, pre-registration only. For more information and pre-registration, contact Hamcon, PO Box 1227, Placentia CA, or phone (714)-993-7140.

CEDAR RAPIDS IA
OCT 19-21

The 1979 ARRL Midwest Division Convention and CVARC Hamfest will be held on October 19-21, 1979, at the Five Seasons Center, Cedar Rapids, Iowa. Tickets are $4.00 in advance or $5.00 at the door. Forums will include FCC, ARRL, DX, antenna, AMSAT/OSCAR, FM and repeaters, microprocessors, modern CW, and more. A flea market will be held at $5.00 per table with 150 tables available. Reservations are good for Saturday and Sunday and must be paid in advance. Pre-registrations will be taken through October 1, 1979. Setup begins at 6:00 am Saturday. FCC exams also will be given on Saturday. (Send Form 610 and copy of license two weeks in advance.) There will be many prizes, including a grand prize of a deluxe HF transceiver, a TH6DXX antenna, a HAM III rotor, and a 60-ft Rohn 25G tower. There will be a Saturday-evening banquet, with Senator Barry Goldwater K7UGA as guest speaker. There are many hotels and motels available. Talk-in on 146.34/.94. For information, write Convention, Cedar Valley Amateur Radio Club, Box 994, Cedar Rapids IA 52406.

READING MA
OCT 20

The Quannapowitt Radio Association will hold its annual auction on October 20, 1979, at the Knights of Columbus Hall in Reading, Massachusetts. Doors will open at 10:00 am and the auction will start at 11:00 am. Food and refreshments will be available. Talk-in on 146.52. For information, call Bob Reiser AA1M at (617)-272-6219.

SAVANNAH GA
OCT 20-21

The first annual Hostess City Hamfest will be held on October 20-21, 1979, at the National Guard Armory, Eisenhower Dr., Savannah, Georgia. Admission will be $2.50 in advance and $3.00 at the gate, with tables for $5.00. Featured will be a flea market, ladies' programs, awards, and FCC exams. Talk-in on .37/.97, .10/.70, .28/.88, .63/.03, and 3,975 kHz. For additional information and advance tickets, write the Hostess City Hamfest Committee, PO Box 1237, Pooler GA 31322, or phone (912)-748-6125.

BILOXI MS
OCT 20-21

The Gulf Coast Ham/Swap Fest will be held on Saturday and Sunday, October 20 and 21, 1979, at the International Plaza, located at the west end of the Biloxi-Ocean Springs bridge on Highway 90 in Biloxi MS. Tables are $3 per day or $5 per weekend. Talk-in on 146.13/73 and 146.52. For information, ad-

vance tickets, and tables, contact Al Williams WD5GNR, 311½ DeMontluzin Ave., Bay St. Louis MS 39520.

NORFOLK VA
OCT 20-21

The fourth annual Tidewater Hamfest-Computer Show-Flea Market will be held on October 20-21, 1979, starting at 9:00 am at the Norfolk, Virginia, Cultural and Convention Center SCOPE, Norfolk, Virginia. There will be 60,000 square feet of air-conditioned exhibit and flea market tailgating space available. Featured will be ARRL meetings, DX and traffic forums, and a CW contest. FCC exams are planned for amateur upgrading on Saturday from 9:00 to 12:00 am. A special feature will be a dinner cruise and banquet on the *Spirit of Norfolk* cruise ship on Saturday night for $16 per person, or $30 per couple. Advance registrations are $2.50 (include an SASE) or $3.50 at the door. Flea market tailgate spaces are $3.00 per day. For tickets and information, write TRC, PO Box 7101, Portsmouth VA 23707.

KALAMAZOO MI
OCT 27

The 25th annual VHF Conference in honor of Walter Marburger W8CVQ, founder, will be held on Saturday, October 27, 1979, at Western Michigan University, Department of Electrical Engineering, Industrial Engineering & Technology Building, Room 3034, Kalamazoo, Michigan. At 10:00 am, there will be a morning registration; a final registration will commence at 2:00 pm. At 2:30 pm, Dr. Larry Oppliger will give a welcome. This will be followed by three speakers. At 6:30 pm, there will be a dinner at the University Student Center (by reservation only). For reservations, write Electrical Engineering Dept., Western Michigan University, Kalamazoo MI 49008.

CHATTANOOGA TN
OCT 27-28

Hamfest Chattanooga will be held on October 27-28, 1979, at the Chattanooga State Technical Community College, Chattanooga, Tennessee. Events include FCC exams, prizes, contests, exhibits, forums, and ladies' programs. The indoor dealer area is $15.00 per table and the outdoor paved flea market area is $2.00 per space each day. Talk-in on .19/.79 and 3980. For pre-registration, with prize ticket and information, send $1.00 to Hamfest, PO Box 95, Chattanooga TN 37401.

LONDON ONT CAN
OCT 28

The London Amateur Radio Club will hold its 2nd annual Swap and Shop on October 28, 1979, from 8:00 am until 4:00 pm at Lord Dorchester High School in Dorchester, just off 401. Admission and tables are both $2.00. Featured will be displays and prizes. Talk-in on .78/.18. For more information, write VE3CSK, RR #1, Ailsa Craig, Ontario, Canada N0M 1A0.

MARION OH
OCT 28

The 4th annual Heart of Ohio Ham Fiesta will be held on October 28, 1979, at the National Guard Armory, Marion, Ohio. Featured will be a flea market, prizes, and forums. Dealer space will be available. Talk-in on .90/.30 and .52. For more information, contact Paul Kilzer W8GAX, 393 Pole Lane Road, Marion OH 43302.

FT. MYERS FL
NOV 3-4

The Fort Myers Amateur Radio Club and the ARRL will hold their Hamarama '79 on November 3-4, 1979, from 9:00 am to 5:00 pm on Saturday and from 9:00 am to 3:00 pm on Sunday at the Ramada Inn, on the Caloosahatchee River, Ft. Myers, Florida. A hospitality welcome center will be held on Friday, November 2nd, from 7:00 to 10:00 pm. Featured will be dealer displays, forums, YL and XYL awards, computer displays, and a gigantic flea market. Registration is $2.00 each in advance or $3.00 each at the door. Talk-in on .28/.88, .19/.79, .52, and .94. For information, send an SASE to Bob Sloat K4VGN, PO Box 05-37, Tice FL 33905, (813)-334-6190, or Don Redd WD4ERQ, 1857 Sunset Place, Ft. Myers FL 33901, (813)-332-1825.

WEST MONROE LA
NOV 11

The Twin City Ham Club will sponsor North Louisiana's annual "Hamfest" on Sunday, November 11, 1979, from 8:00 am until 3:00 pm at the West Monroe Civic Center, North 7th Street and Ridge Avenue, West Monroe, Louisiana. Tickets may be purchased at the door or in advance for admission and for the prize drawings. Featured will be swap tables for buying, selling, or trading amateur and related equipment, displays of new radio and electronic equipment, information on becoming an amateur operator, and prizes. Everyone is invited. The building is heated and cooled for your comfort. Talk-in on .25/.85, .52/.52, and 3910.

FRAMINGHAM MA
NOV 11

The Framingham Area Radio Association will hold its indoor electronic flea market on Sunday, November 11, 1979, from 10:00 am until 2:00 pm at the Framingham Police drill shed behind the police station, Framingham, Massachusetts. From Rte. 9, take Rte. 126 south to the center of Framingham. Sellers' setup time is from 9:00 am to 10:00 am. Advance table reservations will be $5.00, with tables available at the door for $7.50. Refreshments will be served outside the flea market area. Talk-in on .75/.15 and .52. For information or reservations, write Framingham Area Radio Association, PO Box 3005, Framingham MA 01701.

CLEARWATER FL
NOV 17-18

The Florida State ARRL convention will take place on November 17-18, at the Sheraton Sand Key Hotel on Clearwater Beach, Clearwater, Florida. An Icom 701 HF station is the main door prize. The latest update on WARC proceedings is just one of the interesting forums we have scheduled. FCC exams will be given on Saturday at 9:00 am. Please send 610s to the Tampa office by November 9. There will be ladies' events both days, with a luncheon and style show on Sunday. Tickets are $5, which includes a Tappan microwave oven as first prize. The QCWA Gator Chapter will host the Saturday luncheon, with all hams and guests welcome, too; tickets are $6. Saturday evening banquet tickets are $9. Swap tables are $10 for both days—no one-day tables, all advance sold. There should be plenty of parking with courtesy buses running on demand for the duration of the hamfest. We have arranged for special room rates at $30 double, per day, with each extra person $4 and kids under 18 free. Hamfest donation is $3; each advance ticket includes two free prize tickets. Talk-in on .37/.97 and 223.34/224.94. Please make all reservations through and checks payable to: FGCARC (Florida Gulf Coast Amateur Radio Council, Inc.), PO Box 157, Clearwater FL 33517. For ham convention and hotel reservations, phone (813)-461-HAMS.

MASSILLON OH
NOV 18

The 22nd annual auction, Auctionfest '79, sponsored by the Massillon ARC, will be held on November 18, 1979, from 8:00 am until 5:00 pm at the Massillon Knights of Columbus Hall, Massillon, Ohio. The flea market opens at 8:00 am, with auction action at 11:00 am. There will be prizes and displays. Talk-in on 146.52 simplex. Tickets are $2.00 in advance; table reservations are $1.00 per table. For further info, write to Joe Turkal K8EKG, 1234 Concord NW, Massillon OH 44646.

FORT WAYNE IN
NOV 18

The Allen County Amateur Radio Technical Society is sponsoring the seventh annual Fort Wayne Hamfest on November 18, 1979, from 8:00 am to 4:30 pm in the Allen County Indiana Memorial Coliseum, Fort Wayne, Indiana. For more information, write Victor M. Locke, Reservation Chairman, 1415 Edenton Drive, Fort Wayne IN 46804, or phone (219)-432-8047.

OAK PARK MI
NOV 25

The Oak Park High School Electronics Club will present a Swap 'n Shop on Sunday, November 25, 1979, at Oak Park High School, 13701 Oak Park Blvd., Oak Park, Michigan. Donation is $1.50 and tables are $2.50. There will be refreshments and door prizes available.

Ham Help

I was recently sent a General Electric 40-channel mobile Citizens Band AM transceiver by a relative in the USA. I would like to convert this rig to the 10-meter band. A friend lent me some copies of *73 Magazine* and I see you've been running articles on this conversion, but I didn't see any covering my set. It's a model 3-5801.

Could any of your readers help me with this conversion? I promise to try to work you with this rig once it's on ten!

Incidentally, 27-MHz CB from the USA can be heard over here quite well when the skip is right.

My own equipment at present is Sommerkamf FLDX500 and FRDX500 and I operate all bands 80-10 at 100 Watts output, although I have an FL1000 amplifier which can go up to 600 Watts.

I hope some of your readers might be able to help me. The full name of the village QTH here is LLANFAIRPWLLGWYNGYLLGOGERYCHWYRNDROBWLLANTYSILIOGOGOGOCH. So if anyone wants a QSL from the (I believe) second largest place name on earth, just let me know.

from page 32

with pre-cut and pre-bent leads. You won't be pushing diodes with plier-nicked leads or the wrong spread into the sockets, damaging the contacts. For this reason, if the 50 diodes supplied aren't enough (unlikely), I recommend ordering the extras from Drake. Since the extra offsets beyond the standard ones are set up on a diode board, elimination of diodes would require the oddball offsets to be set up with switches on the front panel. That wouldn't be a bad idea, anyway.

The power connector is a 2-pin Jones with the pins exposed on the back panel. There ought to be a guard around it to protect the pins from damage if the unit is dropped. Recessing would be better, but there isn't room inside. Also, there should be some kind of locking feature to keep this connector from vibrating off in mobile operation.

The accessory connector is very well thought out as to the functions provided on it, but it needs to be relocated to the back panel and changed to a type that permits a strain relief on the cable.

Because of heat sink limitations, the transmitter cannot run continuously at 25 Watts. This should never be a problem in two-way voice operation, but continuous RTTY or data transmission would require either reduced power or additional cooling.

Like almost all other transceivers, the UV-3 puts the encoder, if present, on the back of the mike. That makes safe phoning while in motion a rather uncertain proposition. The encoder keyboard for any mobile rig should be mounted on something that is secured to the vehicle, such as the control panel, to allow operation with one hand on the wheel and both eyes on the road. The oft-proposed solution of stopping to phone is no answer if the problem involves reporting a drunk driver and keeping him in sight until the police come up.

The UV-3 represents a big step forward in fitting a VHF transceiver to the needs of the amateur service. On the other hand, the fit isn't quite perfect yet, and a little more tailoring would be in order either on the next product or after they take another look at the placement of the controls on the panel. We hope Drake won't be seduced in the direction of copying any of the more spectacular but irrelevant features of competing products.

We are unlikely to see a transceiver of higher basic quality, especially at ham prices. In many of the most important performance specifications, though, quality is as high as ham applications require, so that improvement is probably not even definable. Various added features could be conceived to fit the unit to specific operating situations, but the accessory jack provides plenty of hooks for doing such things outboard.

I, for one, won't hold my breath waiting for a better transceiver to come along. *R. L. Drake Company, 540 Richard St., Miamisburg OH 45342; (513)-866-2421.* Reader Service number D11.

USER REPORT: THE DATONG FL1 AUDIO FILTER

The audio filter has become an increasingly popular add-on device in the amateur station. The reasons are clear. Today's amateur bands are becoming more crowded as more and more amateurs are licensed in the US and abroad, and more broadcasters and intruders sneak onto our frequencies. With the tremendous increase in QRM, amateurs have had to search for ways to improve reception ability. To some extent, recent developments in receiver design and construction have helped, but unfortunately there is a trade-off for the improvement: It is expensive!

Audio filtering has become popular because it helps to reduce the increased QRM, is relatively inexpensive, is simple to install in a receiver audio line, and is an effective filtering technique for everything except front-end overload and intermodulation.

The current state of the art in audio filters can best be seen in the Datong FL1 "Frequency-Agile" filter. It is manufactured in England and is truly the Rolls Royce of the current filter market. The FL1 has all of the most advanced features available in audio filtering, plus a couple that are unique.

By far the most unusual feature of the FL1 is its remarkable automatic notch system. With this system in operation, the filter automatically seeks out carriers and heterodyne whistles and suppresses them. If, for example, someone plops a big carrier near a frequency one is operating on, he will hear the carrier for about a second, and then it will practically disappear, totally automatically. The S-meter reading, of course, will not change, but the operator will not hear the carrier any more and will hear the signal he wants to hear. This feature is especially effective on 40 meters, where it serves well to combat all of the broadcast carriers. I have had QSOs on 40 that would have been impossible without the FL1, and it works well on other bands, too. Tuner-uppers and carriers are no longer a problem.

The filter accomplishes this feat through a highly ingenious phase-locked loop system. Not only does the phase-locked loop system allow for automatic notch tuning during SSB operation but it also provides another feature, a limited automatic frequency-control system which allows for easy receiver tuning with even the narrowest of bandwidths. The filter will crank down to a bandwidth of 25 Hz rather smoothly and with no ringing, although it is easy to tell that it is right on the verge of ringing, especially with high-speed CW.

In typical SSB operation, the automatic notch system is left operable. SSB signals can be either peaked or notched, although I have found that peaking generally works best. When adjacent QRM and splatter are severe, the automatic notch system can be defeated to allow for manual tuning of both the bandpass width and the center frequency of the filter. Here the FL1 has advantages over many of the audio filters now available. First, the gain of the filter is independent of bandwidth. This means that the bandwidth can be narrowed without affecting the gain of the audio, whereas on many filters it is necessary to readjust the volume whenever the bandpass is narrowed. When the FL1 bandpass is set on an extremely narrow setting, there is a slight reduction in gain, but not nearly so pronounced as with most other filters.

Second, and more important, the bandwidth of the filter is independent of its center frequency. In some filters of the constant-Q type, it is necessary to alter the bandwidth whenever the center frequency is changed. This is not so with the FL1, and the result is a smooth "feel" to the filter frequency tuning which approximates receiver tuning itself.

The FL1 is more effective for SSB work than other audio filters I have tried. Normally, I leave the filter in the automatic mode when I am on SSB and it does all the work. It knocks out any nearby carriers, CW or RTTY, that show up. When QRM gets tough, though, I switch to manual control and adjust the bandpass and center frequency for maximum intelligibility with minimum bandwidth.

On CW, the automatic notching system is normally left off because it will tend to notch out the signal one wants to listen to. The FL1 is very smooth on CW, even at extremely narrow bandwidths. This is due to the fact that it contains a limited afc function with a bandpass width of about ±50 Hz, making the filter tune smoothly across a wide range of center frequencies. On filters without this afc feature, it is difficult to tune in (or notch out) desired signals at extremely narrow bandwidths due to drift and varying frequencies in a net or roundtable. On the FL1, however, the afc action keeps the filter on the received signal.

Should you wish to operate without the afc feature, all you have to do is push in a button labeled -afc and the function is disabled. Normally, for CW work, I use the filter in the peak

The Datong FL1 audio filter.

position with fairly narrow bandwidth. It is then possible to vary the center frequency and tune across several CW signals, even though they may be practically on the same frequency. One ends up with a narrow window which can be moved up and down a number of signals, letting in only the one wanted. The filter works so well on CW, even in heavy contest operation, that I have decided not to purchase the optional CW crystal filters for my new solid-state transceiver.

The filter has its own audio amplifier circuit which will deliver about 2 Watts into an 8-Ohm load. This is sufficient to drive headphones easily and speakers at all but the loudest levels. Even with the volume turned up high, the audio is smooth and distortion-free. It sounds very good in a pair of 8-Ohm stereo headphones.

The FL1 has a comprehensive switching and control arrangement with three variable knobs and five push-buttons on the front panel. The knobs and buttons are large and easily accessible, which, in this age of ever-increasing miniaturization, is a pleasant change. One of the knobs controls the bandwidth and varies it from 25-1000 Hz in the peak mode and from 20-800 Hz in the notch mode. A second knob controls the center frequency, varying it from 280-3000 Hz. The third knob controls the volume and is ganged with an adjustable pot on the back of the unit which allows the input level from the receiver to be preset at any desired level. This gives considerable flexibility in the type of headphones and speakers which can be used with the FL1, and it also ensures that the audio level coming out of the speaker will be constant whether the FL1 is on or not.

The five push-button switches turn the unit on and off, turn the afc function on and off, turn the automatic notching feature on and off, control whether the filter is in the peak or notch position, and allow the filter to be left on but bypassed. One front-panel LED indicates when the unit is on and another one, labeled "lock," indicates when the automatic notch has captured a carrier on SSB or when a signal has been correctly tuned in and peaked on CW. The headphone jack is also on the front panel.

The unit is obviously of high quality construction, with two printed circuit boards and quality components packed into an attractive, high-impact plastic case. The unit is bypassed against rf, and I have noticed no rf getting into it except on a couple of occasions when I have operated the amplifier into extremely high swrs. The FL1 is a complex filter with numerous functions, and it therefore is packed with parts, including eight ICs, six transistors, and eleven diodes. It requires power of between 6.0 and 16 volts at about 100-300 mA, depending upon how much audio is needed. I use a little 12-V dc supply which works quite well. Provision is made internally to plug in a standard nine-volt battery.

The FL1 is a super filter, but no piece of gear is perfect, and this one does have some minor problems. First, it uses identical DIN jacks for the speaker/headphone output and for the power supply input. The filter itself is protected against improper plug-ins, but it might be possible to destroy a power supply if one accidentally plugged it into the wrong jack. Second, the unit is very lightweight (a little more than 1½ pounds), and it will slide across the table when one tries to push in one of the push-buttons. I have had to weigh mine down to get it to stay still. Third, the price for the unit is somewhat steep at $179.95 (although lately several other filters have come out in the same price range).

The FL1 is, however, worth the price. I have used both home-brew and commercial audio filters in the past, but I have never used one that even begins to compare to the FL1. I have found that most audio filters work well on CW but are virtually worthless on SSB, and this is where the FL1 shines. It is far and away the best filter for SSB work I've used, not only when it is in the automatic mode and doing the work itself, but also when it is in the manual mode and one controls the bandwidth and center frequency. And on CW, the FL1 compares to any other filter I've used until it gets down to extremely narrow bandwidths. There, because of its afc function, it performs better than the others. Since I have decided not to purchase any of the optional crystal filters for my new solid-state transceiver, the filter has practically paid for itself already.

Audio filtering has been proven to be effective, and with all of the filters coming out on the market, obviously it is becoming more popular. It is somewhat surprising that more of the manufacturers have not included audio filtering in their transceivers and receivers. Until they do, we shall have to continue using add-on devices, and, of those on the market today, the Datong FL1 appears to be the leader. *Datong Electronics Limited, Spence Mills, Mill Lane, Bramley, Leeds LS13 3HE, England, UK.* Reader Service number D62.

OK's "Just Wrap"TM tool.

OK INTRODUCES REVOLUTIONARY WIRING TOOL

OK Machine and Tool Corporation has announced "Just Wrap"TM, a revolutionary wiring process and series of tools that produce wire-wrapped connections without prior stripping or slitting of the wire insulation. Designed to wrap on .025-inch square posts, each tool carries a 50-foot spool of 30 AWG wire. The tool will wire continuously through any number of pins (daisy chain). It is equipped with a handy built-in wire cutoff and is equally suited for point-to-point wiring. Wire is available in 4 colors: blue, white, red, and yellow.

For further information, contact *OK Machine and Tool Corporation, 3455 Conner Street, Bronx NY 10475.* Reader Service number O5.

THE AD-1 AUTODIALER

You are fighting bumper-to-bumper traffic during the drive home after a hard day at the office. Suddenly, a car in the opposite lane swerves out of control and causes a serious accident. The confusion that results does not allow you to take your hands off the wheel for more than a second or two. Luckily, you recently installed an autodialer on your two-meter rig. Only two buttons are pushed (one to access the patch, another to dial the number) and you are in touch with the nearest police station. Not only does the Advanced Electronics Applications (AEA) AD-1 autodialer make autopatch operation easy, but it also makes it safer for you and your fellow motorists.

The AD-1 resembles a normal touchtone pad, except that it is slightly thicker and heavier. The tough black plastic case contains the circuitry necessary to store and recall ten seven-digit numbers, provide easy callback, and act as a conventional touchtone pad. An additional eight numbers may be stored in a special factory-programmed chip. The design makes hookup to most amateur FM transceivers a simple task.

The heart of the AD-1 is four integrated circuits which provide tones that will satisfy even the most stringent repeater. The keyboard contains the ten

numerals plus the * and # functions. The user gets a reassuring click when a keypad is depressed. Other features include a small speaker so that the output may be monitored, as well as a periodic warning tone when the unit is in the program mode.

The AD-1 comes with a four-pin microphone connector and a short length of coiled cable. Depending on the rig, it may be interfaced between the microphone and transceiver or hooked to an accessory socket. The push-to-talk method involves acoustical coupling. This is a bit more awkward, but involves no permanent connections other than a 12-volt supply. An internal potentiometer allows user adjustment of the output level. If you are only interested in acoustical coupling, then the AD-1P might be a good choice. It is identical to the AD-1, except for the fact that it has only a speaker for output and contains a rechargeable battery.

The $129.95 price might seem high for an occasional autopatch user, but with a bit of imagination the AD-1 and AD-1P could be incorporated in a variety of telephone projects. The 26-page instruction booklet gives a fair description of the various modes that are available.

Autopatch operation has always been a great way to show off the utility of ham radio. Now, you can make it safer and more fun with the AEA autodialer. *Advanced Electronic Applications, Inc., PO Box 2160, Lynnwood WA 98036; (206)-775-7373.* Reader Service number A94.

THE QSL ORGANIZER

With today's more sophisticated rigs and less cluttered radio shacks, how do you keep QSL cards neatly organized, well preserved, dog-ear resistant, and always on beautiful display?

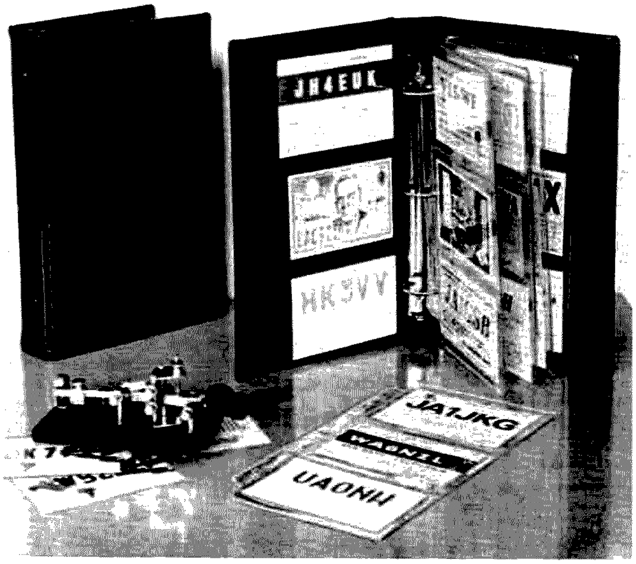
A specially designed organizer is now available from Mil Industries of Panorama City, California. The QSL Organizer contains heavy-duty plastic pages with roomy 4" x 6" slip-in pockets. Each page holds 6 QSLs (back to back), enhancing their appearance by its crystal-clear clarity. The slip-in pockets, accessible from the top, allow cards to be arranged or rearranged quickly and easily.

The QSL Organizer album is specially designed to hold the slip-in pocket pages. It's a beautiful 9" x 14" three-ring binder, richly padded in long-lasting "Brown-Hide" vinyl, with a gold-printed inscription on the cover and spine. Pages are easily inserted or removed.

For further information, contact *Mil Industries, PO Box 44457, Panorama City CA 91402.* Reader Service number M117.

THE XITEX MRS-100 MORSE CODE TRANSCEIVER

The increasing popularity of microcomputers has done more for ham radio than just improve repeater control and advance RTTY operation. The Xitex MRS-100 Morse code transceiver will be of interest to the newest Novice as well as the old-time CW operator. When used with a standard ASCII or Baudot terminal, it becomes possible to generate and receive Morse code at any speed between one and 150 words per minute.



The QSL Organizer.

The heart of the MRS-100 is a 3870 microcomputer. It contains 2048 bytes of ROM which hold the programming necessary to generate and copy code. The result is a single MOS integrated circuit which will convert a Morse input (dc levels) on one pin to a serial ASCII or Baudot output on another pin, and convert a serial ASCII or Baudot input on a third pin to a Morse output on a fourth pin. By adding a power supply, 80-Hz filter, and the necessary switching and interfacing, a complete transceiver is created.

The success of a dedicated microcomputer lies in the quality of the internal program. A MRS-100 owner doesn't need to worry about being at the mercy of the ROM's contents. Xitex spent several years developing the most versatile approach possible. The copy algorithm is compensated to accept a wide range of fists at speeds that will meet anyone's needs. Most code receiver systems assume arbitrary values for the relationship between code element spaces, character spaces, and the dot/dash ratio. The MRS-100 does not. It continually evaluates the received signal, allowing speed shifts from 150 to 1 wpm, or vice versa, missing only about five characters before locking in on the new rate or style.

The problem of generating Morse characters is somewhat more straightforward. The MRS-100 goes beyond the usual Morse keyboard utility since it contains a 32-character FIFO (First In, First Out) buffer. This allows the operator to type faster than the transmitted code and results in a smooth, clean signal. If an ASCII keyboard is used, it may be possible to RUBOUT mistakes so that the ham on the other end hears perfect CW.

The MRS-100 tested at *73* came assembled, in an attractive 7-inch by 8-inch by 3½-inch black and grey cabinet. The 43-page instruction manual includes guidelines for the assembly of the kit version as well as information on hookup and use. Ideally, the Xitex SCT-100 video terminal should be used as the display device. However, a Model 33 Teletype® was pressed into service for our tests. The hookup directions left something to be desired if you were not using an SCT-100 or an older Baudot machine. The addition of a reed relay and diode were necessary to get the system up and running. The frustration of interfacing was soon offset by several hours of enjoyable use.

The Extra class portion of 40 meters was the first testing ground. The headphone jack on a Kenwood TS-820 provided a source of audio for the MRS-100, and soon I was "copying" code at twice the speed I am accustomed to. It was apparent that other fellows were using a computer, too, since the teletype was spitting out flawless text at 40 words per minute. I guess I was disappointed that this previously uncopyable code did not contain secret messages, so I soon found myself tuning across the Novice band. Needless to say, most of the signals did not sound like they were machine generated, but the MRS-100 easily slid down to the five-word-per-minute range, copying the mistakes in addition to the correct characters.

The Search-Track-Lock switch provides the operator with three distinct copy modes. The search mode allows the unit to synchronize and track the received audio while outputting the corresponding ASCII or Baudot characters. If no instantaneous large shifts in speed are anticipated, the track mode may provide a more stable output. The reduced capture window allows a more accurate determination of the dot/dash and spacing decision points. The third mode is a lock type which is useful when there are frequent noise spikes that may be interpreted as false dots. When the operator switches from the track to the lock mode, the capture window and all internal decision points are locked to their current values.

The threshold control, like the search-track-lock modes, is best understood after several hours of practice. I found that the MRS-100 would occasionally get locked at too high a speed. By adjusting the threshold and the level of the input signal, I was able to overcome these troublesome quirks. The input circuitry for the receiver portion of the MRS-100 is relatively simple, yet the unit is able to compensate for fading, even when the signal is seemingly overcome by noise. There is, however, very little tolerance for an adjacent signal. An active filter circuit with an 80-Hz bandpass provides slightly more immunity to QRM, but I doubt if the MRS-100 would function well under contest-like conditions. In addition to the filtered CW, a completely regenerated Morse signal is available from the local sidetone oscillator. This provides a useful way to set the threshold and input levels.

A two-digit LED display shows the speed of the received signal. This does not have the versatility of the conversion algorithm since there are a number of ways that code spacing can be set. When I used a 6 wpm *73* code tape as an input, the

display read approximately 16 wpm. This is not too surprising when you remember that the *73* tapes use a character speed that is much faster than the word speed. The display provides a good relative indication of speed, but I don't think it can be interpreted literally in most cases.

The sending portion of the transceiver performed well. The code speed may be set from the keyboard or external BCD switches can be wired to do the job. The biggest problem is in keeping up; luckily, the RUB-OUT key on an ASCII keyboard lets you fix errors that are bound to occur if you are not used to high speed typing. Another deficiency involves Transmit/Receive switching. An addendum to the instruction manual shows that a single-pole single-throw switch must be put in series with the rig's keying line. This is in addition to the Send/Receive switch on the front of the MRS-100. One switch is bad enough, but two are cumbersome. This problem could be overcome with a bit of custom wiring and a relay; unfortunately, Xitex gives no suggestions.

Old-timers may scoff at the idea of using a computer to send and receive Morse code, but there are several advantages to the MRS-100 that shouldn't be overlooked. It enables amateurs to transmit CW messages and data at speeds comparable to or better than most amateur teletype operation without the numerous FCC RTTY restrictions to contend with. A "RTTY emulate" function allows the MRS-100 to transmit and receive predetermined code characters for the TTY or ASCII keyboard characters not normally used in Morse operation. Two stations using MRS-100s could thus exchange automated, high-speed transmissions that could replace the need for legalized ASCII. Just hook the unit to your computer and start transmitting.

If you're just a beginner in the world of ham radio, the MRS-100 can help to improve your fist. It's amazing how much difference it can make when you see the results of your sending printed on the TTY. Finally, a code computer can allow nonhams to share in the excitement of CW operating.

The MRS-100 is available in three forms. An assembled version costs $295, while a complete kit goes for $225. A partial kit consisting of the microcomputer components and circuit board can be had for $95. Approximately $70 worth of additional parts are needed to complete the partial kit. As computers become commonplace in the ham shack, we are bound to hear a lot more comments like "Keyer here is a computer; it copies the code, too." With the MRS-100, you can brag about your automated station at any speed between 1 and 150 wpm! *Xitex Corporation, 9861 Chartwell Drive, Dallas TX 75243; (214)-349-2490.* Reader Service number X3.

HUSTLER INTRODUCES NEW TEN-METER YAGI ANTENNA

A new beam, designated the 10-MB-4, is the conclusion of extensive design refinements of previous beam technology. The result is a four-element yagi optimized for best directivity, excellent front-to-back ratio, and maximum gain through selective element spacing and precisely resonated element length.

The 10-MB-4 employs a gamma match feed system and is fully adjustable for a 1.2:1 or better swr at resonance.

The mechanical structure of the Hustler 10-MB-4 is ruggedly designed to withstand severe weather yet light enough to be accommodated by a TV antenna rotor. The entire antenna is constructed from high-strength aluminum tubing and can be easily grounded for lightning protection.

For further information, contact *Hustler, Inc., 3275 North B Avenue, Kissimmee FL 32741.* Reader Service number H36.

THE HEATHKIT DEVIATION METER

Have you ever had someone tell you that you were overmodulating on your two-meter FM rig? One solution to overmodulation is the new Heathkit™ Deviation Meter Kit (IM-4180) from the Heath Company. This deviation meter can be a useful addition for anyone who operates FM equipment. At a cost of $149.95 it is not for everyone, but it will permit more amateurs to check their equipment's deviation levels accurately.

Construction

The kit can be constructed in two or three nights. Only two printed circuit boards are used, a main circuit board and a converter one. All components (except the front-panel controls, the front-panel jacks, and the meter itself) are mounted on these two circuit boards. The front push-button switch assembly solders directly to the circuit board and simplifies assembly. The kit uses eight integrated circuits which are mounted using IC sockets. Six of these are RCA COS/MOS operational amplifiers which help minimize current drain but require cautious handling.

The main circuit board holds all of the circuitry except for the converter circuitry and the front-panel mounted items. The converter circuitry is mounted on a separate circuit board which is mounted in a shielded enclosure on the rear of the front panel.

Calibration

The alignment and calibration requires only one piece of external equipment. The deviation meter's local oscillator can be aligned using a frequency counter or a standard FM broadcast receiver. The front-panel meter is used for alignment and calibration metering.

Operation

The deviation meter requires ten AA cells for operation. The manual indicates an operating life of about eighty hours for either zinc-carbon or alkaline cells. A battery charger/eliminator for use with nickel-cadmium batteries is an optional accessory. Battery voltage can be checked by the use of the front-panel BATT push-button.

A tune switch allows you to peak the meter indication using the main- and fine-tuning controls. The fine-tuning control is a potentiometer which controls a varactor diode in the local oscillator. The fine-tuning control simplifies tuning at VHF and UHF frequencies. Operation from 25 to 50 MHz uses the local oscillator fundamental output, but operation from 50 to 1000 MHz uses the local oscillator harmonic outputs. A dual-gate MOSFET is used as a variable frequency oscillator. This is a diode-protected device, and while no precautions are given in the manual, I advise caution when installing this transistor, since the one I installed failed to operate. A replacement was installed with no problem. A hot-carrier diode is used as a frequency-converting mixer. An i-f gain control is provided on the front panel to control sensitivity. Between 50 and 500 MHz, the deviation meter has a minimum sensitivity of 35 mV. Accuracy (full scale) is specified as plus or minus three percent.

Meter ranges of 0-2, 0-7.5, 0-20, and 0-75 kHz peak are selected by front-panel push-buttons. The 0-7.5-kHz range is useful for setting the FM deviation of amateur equipment. The 0-2-kHz range uses a low-pass filter and is most useful for adjusting continuous tone-coded squelch systems. The deviation meter uses a pulse-counting detector operating at a 200-kHz i-f.

A speaker output jack is provided for an external speaker (no internal speaker is provided). The audio amplifier provides 100 mW minimum into an 8-Ohm speaker. A front-panel switch selects a de-emphasis of 750 us for two-way radio, or 75 us for standard FM broadcast. This de-emphasis switch affects only the speaker output.

A scope output is provided on the front panel. This output provides a nominal 13-mV/kHz peak superimposed on a dc voltage of about 2.7 volts. This output permits you to monitor the input for clipping which would not be apparent from the meter reading.

Conclusion

I enjoyed constructing my Heathkit deviation meter and find it simple to operate. Its portability makes it ideal for checking the local repeater or your friends' equipment. I particularly like the ease with which subaudible tone levels can be checked. *Heath Company, Benton Harbor MI 49022.* Reader Service number H5.

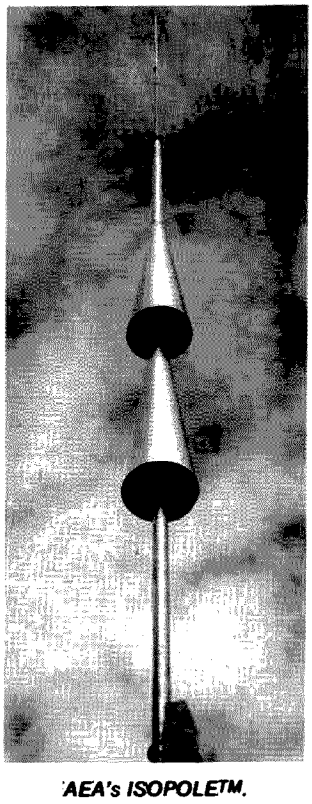
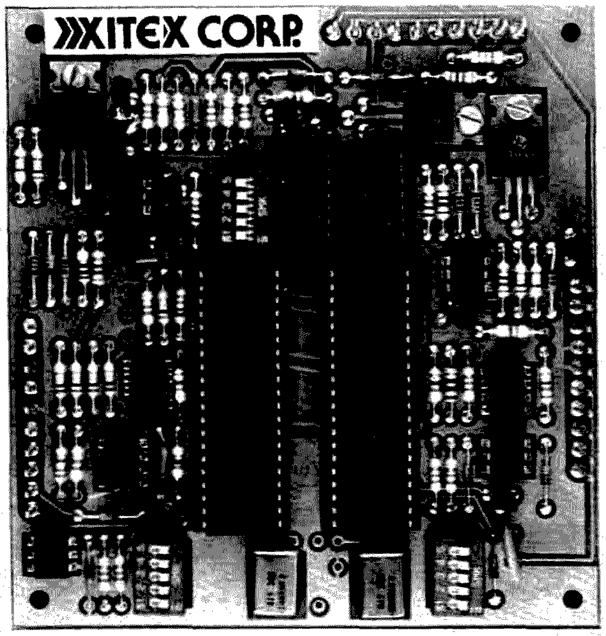
THE ISOPOLE™

AEA (Advanced Electronic Applications, Inc.) has developed the ISOPOLE™, a new vertically-polarized, omnidirectional, gain-type base station antenna which provides truly superior performance over any other low-cost antennas now in the marketplace. ISOPOLE's



AEA's ISOPOLE™.



Xitex's ABM-100 code converter.

revolutionary double-cone design results in virtual elimination of the major problem plaguing other base-driven vertical antennas. This problem is the inadvertent and unwanted coupling of rf currents onto the supporting structure and the shield of the feedline, seriously degrading the radiation patterns of most competitive antennas. On-the-air field tests have shown a substantial signal improvement in favor of the ISOPOLE when switching between the other competitive antennas and the ISOPOLE.

The ISOPOLE's unique new design features a double-decoupled, center-driven, 1¼-wavelength antenna to provide maximum theoretically obtainable gain for a dipole. All rf connections are protected from the weather. The ISOPOLE is pre-tuned at the factory so that the user can obtain an 8-MHz bandwidth by following the simple assembly instructions. The ISOPOLE is intended for installation atop a standard TV mast (not supplied) and is packaged in a 7" x 7" x 29" shipping container.

Heathkit's new catalog.

MICROCOMPUTER-BASED CONVERTER TRANSLATES ASCII/BAUDOT/MORSE

A new single-board code converter, designated the ABM-100, is now available from Xitex Corporation for translating between ASCII and Baudot or Baudot and ASCII. Utilizing a pair of MK-3870 single-chip microcomputers, the board provides two independently programmable serial data ports which are internally connected. Programming is accomplished using on-board DIP switches for selecting the baud rate, line length, and data format for each of the two ports.

Eight different baud rates are provided, from 110- to 1200-baud ASCII and from 45.45- to 74.2-baud Baudot. Output line lengths of either 40, 64, 72, or 80 characters are also selectable.

Other features include a built-in FIFO buffer, interfaces for both RS-232 and 20/60-mA current loop operations, and speed conversion capability.

A third port is provided for translation between Morse code and either ASCII or Baudot. This permits the generation and decoding of Morse signals (dc levels) using conventional ASCII or Baudot equipment.

For further information, contact *Xitex Corporation, 9861 Chartwell Drive, Dallas TX 75243; (214)-349-2490.* Reader Service number X3.

NEW HEATHKIT CATALOG AVAILABLE FREE

A completely new 96-page catalog, describing nearly 400 electronic kits designed for the do-it-yourselfer, is now available from Heath.

Product categories offered include electronics learning programs, test instruments, convenience and security products for the home, stereo components, color television, auto, marine, and aircraft accessories, personal computer systems, and much more.

New products in this catalog include the All-In-One H89 computer with floppy disk storage, a five-antenna remote coax switch for use in amateur radio, a 3½-digit autoranging multimeter, a low-priced dc-to-5-MHz single-trace oscilloscope, a portable solid-state VOM for the hobbyist, and professional quality audio equipment.

For further information, contact *Heath Company, Department 350-880, Benton Harbor MI 49022.* Reader Service number H5.

TEN-TEC'S MODEL 232 SWITCHER/25

Within recent years, transistor switching power supplies have come into wide use for sophisticated electronic equipment. They are characterized by the use of high frequency transformers and transistor switching to produce the regulated output voltage.

Switching power supplies are more complicated than the conventional pass-transistor types and are more expensive. However, they offer many advantages over conventional types. Some of these are greater efficiency, cooler operation, lighter weight, excellent regulation, protection against overvoltage, better reliability, and the capability of being powered by 117 to 230 volts, either ac or dc.

Ten-Tec has announced a state-of-the-art switching power supply, the Model 232. It can be used to power any Ten-Tec transceiver or any other 12 V dc system, with current requirements up to 25 Amperes.

In operation, the 117- or 230-V ac input is first rectified to approximately 160 V dc, plus and minus, using a doubler for 117 V ac and a bridge configuration for 230 V ac. This high dc voltage is applied to a switching circuit to produce pulses at 25 kHz. The internal oscillator that applies the switching signal to the transistors also adjusts the pulsewidth in accordance with a feedback circuit from the output line, so that the average value of the pulse train is 13.5 volts, plus a small amount of loss. The pulsewidth-controlled signal is then rectified and filtered to the 13.5-volt output. No heavy 60-Hz power transformers are needed with this system, and should the switcher stop oscillating, the output voltage drops to zero instead of a high dc value.

The Model 232 complements the OMNI transceiver series in cabinetry and cable and connector compatibility. For further information, contact *Ten-Tec, Inc., Sevierville TN 37862.*

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

from page 20

just encourage them to waste more . . . like the government.

The League can make money so they will be able to do the jobs we expect them to . . . such as get amateur radio established on a good footing in most of the Third World countries . . . and put up a more intelligent battle against FCC rules which are harmful. To do this, they need someone running the place with some business background and, as far as I can see, they don't have it.

The ads in *QST* should bring in about $3 million per year . . . and so should the memberships. Books should bring in another $1.5 million, at least. With expenses around $5 million, that should leave a good supply of money for ARRL activities and lobbying.

220—USE IT OR ELSE

The makers of marine radio equipment certainly showed up the CB manufacturers for a bunch of yokels when it came to grabbing off a chunk of a ham band for commercial use. You can put me down as paranoid for thinking of the job as an accomplished fact, but we'll see what the bottom line is when all is said and done.

The CBers, led by the ex-Hy-Gain people, got the idea that they could sell everyone on CB rigs again if they got a new CB band opened up. And this one would be bigger and better than the 23 channels that were then making them rich. Quite a bundle of money was poured into the effort, and it looked as though it might just make it. It would be interesting if an investigative reporter could spare the time to try to find out where a whole bunch of lobby money was spent on this project. it went first to the EIA, as I understand it. Then I noticed that a chairman of the FCC started acting very strange, being totally convinced of the need for a CB 220-MHz band despite the contrary advice from his technical staff. Was this a coincidence?

In my younger days, I used to think well of everyone and be very surprised when I discovered that things were not always what they appeared. Then, as I looked more carefully, I found that things are seldom what they appear. And I think this holds in spades for politics and our beloved government.

And why, if this chap were not in the lobbyists' pocket, did a major equipment manufacturer at the time want to bet with me that 220 would soon be a CB band . . . as he was bringing out a new 220-MHz transceiver? And why did the FCC chairman, who then went on to the White House staff, keep the pressure on for the CB 220 band? Why would he care any more about that once he was out of the FCC?

The maritime equipment manufacturers have long wanted to get the ham 220-MHz band for marine use. Think of the radios some four million pleasure-boat owners would be buying! Now, I don't know how they managed to get their way with the US WARC preparatory group, but they pulled the sleeper of the decade on amateur radio when their plan suddenly appeared in the finished report.

Amateur groups have been furious about this, pointing out that the whole thing was totally illegal. The final report was made on matters which had not been through the legal hurdles prescribed by the Administrative Procedures Act—with no Notice of Inquiry and the usual fact-gathering and discussion stages. No, this crafty (pardon that!) bunch kept the whole thing under wraps and never gave any opportunity for opposition.

The 220-MHz amateur groups are pretty upset over this coup. They've tried to get some satisfaction from the FCC, but have been thoroughly put down. My contacts with the FCC tell me that we lost a lot more than we ever thought when the ham manufacturers refused to cooperate with each other in the linear opposition hearing . . . and then the ARRL's counsel Booth harangued the Commissioners at length, putting them down.

The League is acting as though it is part of the conspiracy, telling the 220 groups not to worry—everything will be all okay. Yes, I'm aware that some of the ARRL directors are going around to clubs saying that I don't know what I'm talking about . . . but you notice that they never challenge me face to face. I have in my files copies of letters from ARRL officials to 220 clubs which say not to worry . . . that the FCC has assured them that all is okay for the ham band at WARC.

My gradually-developed paranoia suggests a rather different story. It tells me to be careful of news like that and to look for the gimmick. In this case, let's look at a scenario. Let's suppose that there is a group that wants more frequencies for a new maritime band. Let's suppose that this group knows damned well that even without any lobby hams can be difficult to put down, so their best approach is not to go the CB route, but to slip something through the back door. We've already seen that they are pretty shrewd at this. I don't think anyone has even figured out who managed the sneak play with the WARC position or how it was done.

Next, let's assume that this group is not stupid enough to think that a lot of other countries thousands of miles away from us and with no substantial pleasure-boating population are going to jump at this proposition. In other words, anyone above the grade of moron is going to know that this proposition is not going to stand the ghost of a chance of becoming international law as a result of WARC. The band involved is a television band in some countries and is not even a ham band in much of the world.

Okay. Now we see that some group spent a lot of time and effort (that means money) getting this into the US WARC position. Knowing that it would be defeated at WARC, why did they invest so much? Well, there is a kicker known as a footnote. The US delegation at WARC can say, shucks fellows, we're sure sorry you didn't go for this fantastic band which we need desperately for our four million pleasure boats, but we agree with your right to decide these things on a one-country, one-vote basis. We also ask that a footnote be appended to the allocations table reserving the right for the US to do as we proposed. A bunch of boats in the US on 220 MHz with low-powered equipment is no hair off anyone in Lesotho, so we get our footnote . . . and we also get a new maritime band . . . and lose a nice ham band.

It is going to be more difficult for the maritime equipment manufacturers to keep this one moving if we get busy and populate the band. But we've been sporting "220, USE IT OR LOSE IT" buttons for several years, and the action is still scanty. Slogans and guilt are not people movers. We'll have action on 220 MHz when enough amateurs are convinced that they should spend the time and money to buy or build equipment for that band . . . and not before.

You get people to do things when they think it is to their benefit. This is why I was so opposed to the very concept of what was jokingly called Incentive Licensing . . . which was anything but that in its original concept. You get people to do what you think best only when they agree that it is going to benefit them. I think this holds for using 220 MHz, and thus I propose that we do something about this.

The 220-MHz groups have been particularly derelict in their approach to the situation, and if the consequences were not so severe for amateur radio, I could almost enjoy their discomfort now that they see the band slipping away from them. For the most part, these groups have been smug and cliquish. They've found a band where they are not much bothered with the rising tide of idiots and kooks who have been making life miserable for some of the 2m repeater owners. They've felt that secrecy is the best answer in order to protect their private preserve. So we see little written for magazine publication and little in the way of reported accomplishments from these groups.

The result of this snobbery is that there are but a few hundred repeaters on 220 MHz and a very few thousand users. When you talk with these people, you find that their reaction is almost universal . . . they think 220 MHz is fantastic, but please don't tell anyone. They like it as it is and don't want the screwballs from two meters to come up and get their kicks.

Well, fellows, you have to make a choice. You have to decide whether it is worthwhile to keep the band for your little group and keep it a secret . . . and possibly lose it completely . . . or whether it is getting time to open up 220 to everyone and perhaps be able to save it.

I think that we should be able to work out some practical solution to the fruitcakes who mess up repeaters. Little has been written of a constructive nature about this, and it is a situation that really needs to be tackled. I get tapes from southern California of some of these goings on, and it's almost enough to get the Ku Klux Klan out recruiting. I don't know how those fellows are able to put up with that crap without wringing a few necks.

220-MHz repeater groups do find some substantial benefits to the band. Their repeaters are generally able to coexist with

most commercial band repeaters without anywhere near the severe intermod problems from which 450-MHz repeaters often suffer. There are still a lot of repeater channels available on this band . . . so perhaps this might be the place to put some of the needed experimental repeaters which will give us access to the lower bands.

I'm still enthusiastic about developing cross-band repeaters which will let us remotely access repeaters hundreds of miles away. I'd like to see repeaters which could double as remote base stations cross-banded to the other ham bands, including the DX bands. With the remote tuning system built into the Icom 701, we have a big start in this direction. We'd need some scheme for indicating the frequency used via the repeater . . . and some way to turn the beam . . . let's see some articles.

When you come down to it, articles in the ham magazines are the answer. *You* do the inventing and the pioneering—then *write* about it, pointing out the fun and things which can be done. These articles will get the action we need. Where would two-meter FM be today if *73* had not published hundreds of articles, several books, and gotten the word to everyone about the fun they were missing? Oldtimers will remember that the first reaction of most hams was that they didn't want to read about it—didn't want to be bothered. But they eventually did read, and then began to read more, and eventually they tried it.

With articles on what is going on, with articles on new ideas and circuits, with articles on new equipment which is available . . . with all this, we will spark interest in hundreds . . . then thousands . . . tens of thousands . . . and we just might make it. It's in the hands of the 220 groups. Write about it or write it off. I guarantee that *73* will try to publish as much good information about 220 as possible.

WARC REPORT

Senator Goldwater, apparently concerned over the conflicting reports about WARC, requested the Library of Congress to prepare a report on the matter. The Library's Congressional Research Service (CRS) did some looking into the situation and reported, "The official US approach to the . . . conference could be characterized as one of cautious apprehension. There has been a change in public stance since early May; until that time, Department of State officials, especially US WARC delegation members, had been expressing a degree of optimism."

The study went on to say that Third World opposition to the US proposals "may prove a considerable challenge to US policymakers and representatives." The problem here is that politics is involved rather than technical considerations. The report said that "the US delegation is not totally pessimistic about the conference's outcome."

Several past ITU meetings turned fruitless because the Third World nations refused to enter technical discussions, but insisted on using the ITU to express their political views and frustrations.

No one can say how this conference may work out, obviously. But the preponderance of evidence and projections of past actions are certainly not comforting.

MORE FAKE HAM GEAR BEING SOLD

Last year, an outfit in Houston, Texas, came out with a police radar jammer, calling it amateur equipment because it had a transmitter built in. The only purpose of this equipment was to jam radar. We surely don't need more illegal equipment being sold under the false pretense that it is for hams when the fact is that it is in no way intended for ham use.

Now this firm, Microwave Devices, Inc., has a new and improved model which is being promoted as a ham transceiver for either X or K band. The dial, which used to be calibrated in mph (the speed it would indicate on the police radar unit), is now calibrated in audio frequency. What a rip-off of amateur radio!

It isn't even necessary to use a transmitter to give police radar units a false indication of speed. We ran an article a couple of years ago showing how to build a completely passive unit which would both indicate the presence of radar and return a reflected modulated signal to it showing the speed of your choice. I presume that most of the people who built this fiendish device are put away safely now in various prisons around the country after discovering that police have no sense of humor. Eventually, every user just *has* to give the fuzz an indication of 200 mph while driving along at 25 mph. The radar is right, and the court believes it, no matter how ridiculous. Any driver going 200 mph should be put away.

The recent cases where police radar units were able to clock a house at 80 mph has hurt the reputation of radar a bit. And not a few hams have been hauled before judges who have had no knowledge of or even interest in discussing the question of false readings on radar units, even when attempts are made to offer proof that a mobile ham rig can throw radar readings almost anywhere.

I'm no fan of police radar. Going slower than normal, namely 55 mph, may save gas, but it sure wastes a lot of my time, which is far more valuable than the cost of the gas involved.

The car magazines have exploded the gas-saving myth anyway, by pointing out that the amount of gas saved by driving at 55 mph instead of 65 mph is far less than we would save if we increased the pressure in our tires by one pound! And as far as saving lives, when you look closely at the actual statistics, you find that we are losing more as a result of the inattention brought on by driving 55 mph on 100-mph roads. They have not put any speed limits at all on roads in most European countries.

POLICE RADAR HELD ILLEGAL!

A Washington DC court recently heard a case against a chap who had been arrested for having a radar detector unit in his car. The court spoke out against this quite clearly. The judge drew the parallel of a driver who kept a pair of binoculars on the seat beside him to look ahead and spot speed traps. Can the law be interpreted so that the citizen can be prohibited from carrying binoculars in the car?

But that was only a small part of the judge's comments. He went on to point out that police use of radar is an intrusion by the government without a search warrant issued on probable cause describing the place to be searched and the persons or things to be seized. He felt that this was clearly an unwarranted search since there is no consent to such a search. The judge said that a citizen using the highways in a vehicle has a right to know whether or not the government is monitoring his actions.

Thus, with no positive evidence that a crime is being committed (speeding), the police have no right to search you with their radar to get evidence against you of this crime.

The court felt that the police infringed upon the citizen's rights under the First Amendment, the Fourth Amendment, the Fifth Amendment, the Ninth Amendment, and the Tenth Amendment to the Constitution, and that the infringement constituted an invasion of a citizen's privacy, a denial of a citizen's right to know what officials of the government are doing, an illegal search and seizure of the citizen's property in an electronic sense, and a violation of the citizen's rights as retained by the people.

Lawyers may want to reference *The Daily Washington Law Reporter*, July 19, 1979, page 1257.

MICROPROCESSORS AT WORK

Well, when I started running microcomputer articles in *73*, I warned you that these fiendish little contraptions would find their way into our radios . . . and they have.

Recently, when I finally managed to con Icom out of a 701 for a test, we plugged it into the ETO 374 linear and a Wilson tribander beam up on a Rohn tower and had at the DX. Mercy me, as the CBers say, what a difference!

It took hardly any time at all to get used to being able to tap out the desired frequency on the remote control unit. I'd hit 14.2000 and *zap*, the radio would be right on 14.2000 MHz. To tune up the band, all I had to do was push the UP button and it would advance 100 Hz at a time . . . or if I held my finger down, it would skip on up the band. I soon got used to stopping on the next voice tuned in almost right on channel. If it was some choice DX, but in a contact, I just would touch the MEMORY, WRITE, and #1 buttons . . . and tune on up the band. Then, every now and then, I would check the DX channel by touching MEMORY, READ, #1 and the rig would pop back on the desired channel.

Hey, maybe ten meters is open! 28.5000 and click-click, I'm listening to ten. Hmmm, I must not forget to switch the band on the linear. To cover the band quickly, looking for signals, I'd switch to the 1-kHz scan position and let 'er rip. Nope, dead . . . so let's go to 21.2500 and check fifteen. After working my way up the band, checking out a few Gs and DLs, I'd run into a JY and a J6, both rare enough to warrant some patience. At the first break of either of these stations, I gave a short call . . . and no answer. Damn, I forgot to switch the linear! More waiting for a break, buttoning back and forth between memory 1 and 2, checking both channels . . . then tuning on up the band, listening for more DX . . . back to the two channels again. I finally got both of 'em.

A PUBLISHING CAREER?

You could do worse. In fact, most people do a lot worse. Despite the cutbacks in employment at the ARRL, amateur radio publishing is doing well as an industry and is both fun and profitable . . . an excellent combination. The staff at 73 has grown from about five ten years ago to 110 at present, though

this includes *Kilobaud MICROCOMPUTING* and Instant Software. Sometimes it is difficult to know who is working how much for what.

We've openings for some people in several departments, and being an active ham is not going to hurt one bit.

We need a ham editor to help Jeff DeTray WB8BTH with editing articles, selecting material to be published, and following up on an endless number of special projects. There just might be some investigative reporting, too.

If we're going to get involved with any kind of a national organization, we'll need a ham or two to coordinate these matters. This might be something a retired military ham could get his teeth into.

Then there is the need for a ham who can both read and write to help Jim Perry in the book department. We'd like to step up our book production to five or six new books a month in the ham and computer fields. A knowledge of microcomputing will help a bit here.

Instant Software has about 30 full-time employees and we're looking for double to triple that in the next few months, which means there are openings for people with experience in marketing, advertising, production, accounting, packaging, data processing, and management. Some computer hobby background won't hurt here, either.

The Peterborough area is completely smog-free . . . you couldn't ask for cleaner air. We ask that all applicants be nonsmokers and not smokers who think they can give it up for a good position.

In additon to the usual dry resumé, I'd like to have a letter telling me what particular qualities you might have for working here. I would prefer people who are anxious to learn a lot and who will be working toward the development of their skills.

Ten years ago, it never even occurred to me that my publishing firm might one day grow larger than the ARRL, but we seem to have arrived at that point this year!

BEEFS

We've received a couple of beefs about a firm called HMR. These people are *not* advertisers in *73*, by the way.

INSTRUCTIONS FOR MAKING SUPERB APPLESAUCE

First, cut up apples, removing the cores and any blemishes . . . spots, bruises . . . but leave on the skins. Cut apples into bite-size chunks.

Put in a large pot, perhaps four to eight quarts at a time, fill one-third to two-thirds full with water (depending on your consistency preference), cover, and bring to a boil. Boil about five minutes at most, and stir the apples now and then to make sure all are cooked about the same amount.

When the apples are fairly soft, turn off the heat and add about ½ cup of sugar for each quart of apples. This will vary some depending on the tartness of the apples. It is difficult to get an apple which is too tart for applesauce . . . I've never found one. Stir in the sugar well and let it cool just a bit.

Spoon the 'sauce into plastic freezer containers, mark with the type of apple and the date, and let them cool. Later you can freeze them with no loss of flavor.

I prefer Transparent apples by far, with the second choice being Duchess . . . then Wealthy. Macintosh and McCowen are okay, but not nearly as great as the first. I had to plant my own trees just to get the type of applesauce I like.

Milder apples may need some lemon juice to add tart . . . use it sparingly and taste as you go. Truly tame apples may even need some cinnamon.

This process of making applesauce is so infinitely better than anything available canned that you will never go back to store applesauce again. Even old, soft apples of the most bland type will make better 'sauce than the best canned stuff.

I often keep a lot of apples in the refrigerator so that I can cut up one or two to have for lunch with some Havarti or Jarlsberg cheese. Eventually these apples get a bit withered and soft . . . so I then 'sauce them . . . you can cut up a remarkable lot of apples while watching TV and not waste your time so totally. I save some videocassette movies for this process.

If you prefer canning yourself, this works fine, too. I like freezing because it is a lot simpler for applesauce and even for jams, too.

Hey, don't strain the 'sauce. The peels of the apples soften up when you cook them and have some of the best flavor. Some peels will give the 'sauce a nice red color.

You have to have your own tree for Transparent or Duchess, both very early apples. They don't last but a day or two when they ripen, so they are not useful for selling. When your Transparents start to get ripe, start shaking the tree every day and don't let 'em ripen all the way on the tree. My first apples this year were ready to eat in mid-July, which is incredible for New Hampshire. I think the Transparent and the Duchess are the finest apples in the world.

JUNE WINNER

"The Voice of Wolf Creek" apparently reached quite a few of our readers, since they voted Dr. William C. Hess W6CK's article of the same name the best in our June issue. Enrich the author of your favorite article by $100 by using your Reader Service card ballot!

PETERBOROUGH FLEA MARKET

As if Sherry doesn't have enough to do, she decided to run a flea market in the parking lot of the 73 West building, in June. That's Sherry in the middle, with Ross, our full-time plumber, on her left, going in to see what he can do with the air conditioning system.

Aline Coutu, our advertising manager, brought over some of the ponies from her stables so there would be pony rides for the kids. One of the nice aspects of living in New Hampshire is that you can have your own stable if you like. Aline has quite a spread, complete with an indoor riding ring, and she and her family board about 30 horses and ponies.

Here are some of the pony rides . . . note the country background! Peterborough is a small town, and just one-half mile from the center of town you start getting into the forested areas. Though only an hour from Route 128 around Boston, Peterborough is a rural area.

Contests

from page 28

may be worked once on each band. The general call will be "CQ ARAC 50."

EXCHANGE:

Arrowhead amateurs send RS(T), county, and state. All others send RS(T) and ARRL section or country.

FREQUENCIES:

CW—3535, 3725, 7035, 7125, 14035, 21035, 21125, 28035, 28125.

Phone—3980, 7280, 14280, 21360, 28560.

SCORING:

Each CW contact with a Novice or Technician counts 5 points; all others count 1 point. Multipliers are: 5 for Novices/Technicans, 5 for 5 Watts or less, 2 for 6 Watts to 200 Watts, 1 for 201 Watts to legal limit. Arrowhead amateurs take the number of points times the sections/countries worked times the multiplier to get the total score. All others take number of points times 5 times the number of counties worked times the multiplier.

AWARDS:

Plaques to top-scoring Arrowhead amateur and top-scoring amateur outside area. Certificates for second and third place and to top-scoring amateur in each ARRL section and country.

ENTRIES:

Logs must show band, mode, date/time in GMT, station worked, exchange sent and received. If more than 100 contacts are made, dupe sheets must be included for each band used. Send entries to: ARAC-50, 123 E. 1st Street, Duluth MN 55802, with an SASE for awards and results. Entries must be postmarked by November 21.

CRAZY EIGHT NET QSO PARTY

The Crazy Eight Net of Pittsburgh PA will hold its first annual QSO party on October 28 and all stations are welcome to participate. Only certificate holders, however, may submit logs! All contacts must be made on 10 meters. Operating period will be the full 24 hours beginning at 0000 GMT October 28. Scoring as follows: Each contact is one point with an additional point for each contact having a 10-X number, and another additional point for each contact having a Crazy Eight number. Maximum point value per contact is 3 points. Awards will be issued to the top-scoring DX station. Submit logs with call, name, QTH, time, frequency of contact, 10-X number, and Crazy Eight number to contest manager no later than November 28. Contest manager is Jim Lundberg WB3ICC, 571 Washington St., McKeesport PA 15132. Enclose an SASE for a copy of the results.

CLUB STATION WD4KOW

Members of the Colquitt County Ham Radio Society will be operating club station WD4KOW from the site of the second annual Sunbelt Agricultural Exposition on October 9, 10, 11, 1979. The hours of operation will be 0900 to 1600 EDST each day.

This annual Sunbelt Expo is the largest agricultural show in the south. The first Expo last year drew 140,000 visitors from all over the United States and Canada during the three-day period, and this year attendance is expected to hit 200,000.

Operations will be mostly on 40 and 20 meters around 7.250 and 14.300 MHz with some operations in the other HF bands. The members will also be listening for visiting hams on the local repeater, 146.19/79. Visiting hams are invited to visit the amateur booth at the Expo and operate the amateur station.

This year, special QSL cards are being printed for this event and will be available for those making a contact and desiring one. For more information, contact the Colquitt County Ham Radio Society, PO Box 813, Moultrie GA 31768.

W3LWW CELEBRATES 20TH ANNIVERSARY

The Foothills ARC of Greensburg PA will be celebrating its 20th anniversary by holding a mini field day from 1400 UTC, Saturday, October 20, through 1400 UTC, Sunday, October 21, 1979.

Phone and CW operation will take place on 10 through 80 meters, 5-10 kHz up from the bottom of the General class portion of each band.

Certificates will be awarded to anyone working W3LWW (SASE required).

AIRSHO '79

An aeronautical mobile operation aboard a Boeing B-29, using the call W5DX, is scheduled to take place during the Confederate Air Force Ghost Squadron's Airsho '79, October 4th to 7th, in Harlingen, Texas. Communications will be available on 14.285 MHz and 21.385 MHz (as propagation permits) during the hours from 12:00 pm to 5:00 pm CDT. Local fixed stations will act as liaison for interested amateurs wishing to make contact with the B-29. A commemorative photo QSL card is planned.

Ham Help

I'm interested in learning about all the modifications which can be made to the Clegg Venus 6m transceiver. I'm particularly interested in reducing the receiver internal noise level.

I have been told that replacement of the 12BE6 converter with a dfferent tube and some wiring changes reduces the noise level. If anyone has any info on this or other changes, I would appreciate hearing from them.

Leon A. Savidge WA3EFE
Box 268, RD #2, Park Ave.
Binghamton NY 13903

I have been contacted by a local Civil Air Patrol (CAP) unit in need of radio equipment. If anyone can donate equipment, operating or not, I am willing to donate my time and parts to repair the equipment and pay shipping charges, if needed. An IRS donation form can be made available to donors for tax use for some equipment.

CAP operates on 4.4-MHz SSB, 28.8-MHz AM, and 143.90- and 148.90-MHz FM. CAP is a volunteer air search and rescue group that has saved several lives of victims of downed aircraft.

If you have any equipment available, or would like more information, please contact me at the address below. Thank you.

Peter J. St. Arnaud
PO Box 695
Lowell MA 01853

I have a Cosmos Industries Cosmophone 35 transceiver that I would like to obtain a manual for. Can anyone lend me a manual or a copy of same? Of course, copying costs would be covered.

Awards

from page 24

123 E. 1st Street, Duluth, Minnesota 55802, before December 1, 1979, to receive this free award.

As time goes on, be sure to continually check this column for announcements of any new awards we may have added to our program. A month doesn't go by that I scratch out another set of Ideas and consider them for submission to headquarters staff. Perhaps you have some ideas of your own. Use your creativity, put your Ideas down on paper, and forward them to me.

In the meantime, continue to work those new contacts whether it's for a new state, city, or DX country; they're all important to you, so don't waste another minute! You work the stations and we'll issue the awards; the *73* Awards Program offers something for everyone!

Next month we will travel overseas and review the various awards being offered by our foreign friends. Additionally, we will look at a couple programs offered by stateside organizations.

LETTERS

from page 14

this may be old news to you. However, I heard the Russians playing with twenty for 45 minutes last night and it hacked me off so much I had to let out anxiety somehow. . .so I wrote you.

Steve Baumrucker WD4MKQ
Chapel Hill NC

P.S. Went back to my rig and the Russians reverted to the old radar system and things were business as usual! Can't figure this one out. . .

2M BEACON

A two-meter beacon station has been put on the air by the Marissa Amateur Radio Club, Inc., on July 1, 1979. This beacon will be to plot propagation and signal paths in the two-meter amateur radio band. The beacon will prove very useful to all who work the VHF spectrum.

The beacon is a project of the teenage group of the 100-member club which is located 50 miles southeast of St. Louis MO. The group will need to make a full report to the FCC at the end of December so all receiving stations are kindly asked to send their reports and weather conditions at the time to the club station, WD9GOE, PO Box 68, Marissa, Illinois 62257, attn: beacon committee.

Technical information:

Frequency—144.050.

Emission—A1 and F1 (a slightly deviated 1-kHz signal is on top of the A1 CW signal so that FM receivers are capable of detecting it).

Power—one Watt output from a VHF Eng. rf strip.

Control—220-MHz link.

Emission control—VHF Eng. CW-ID board with solid-state keying circuits added.

Power supply—12-V auto-type sealed battery with charging circuit.

Antenna—4 stacked dipoles, 2 vertical, 2 horizontal.

Height—250'.

Location—Baldwin, Illinois, 4 miles southwest of Marissa, Illinois, 55 miles southeast of St. Louis MO.

Times of operation are continuous, 24 hours per day.

Bob Hell K9EID
Marissa IL

THE QUEEN

Many thanks for the terrific coverage you gave the Associated Radio Amateurs of Long Beach and me in Bill Pasternak's story about W6RO in the wireless room aboard the *Queen Mary*.

This operation is not just a single PR stunt. With few exceptions, the station operates seven days a week with volunteer hams from throughout the area. I believe this is the only time any public display of amateur radio on a continuing basis has ever been established. So interested are the tourists in the operation that answering questions about ham radio occupies a great deal of our operator's time. As the station is part of the tour, it is estimated that about 80,000 people will see the station in operation during a year.

Again, many thanks for all your interest, from all of us in the Associated Radio Amateurs of Long Beach.

Nate Brightman K6OSC
Long Beach CA

FIRED

In your August editorial, under the subcolumn "WARC," you write that if the ARRL doesn't shape up, you'll do something about it. We both know that the League won't do anything, so it's time you went into action. The winds have been changing for a long time, and the boys in Newington still can't tell from which direction it blows.

I think you can get enough support from progressive and concerned amateurs to make a new organization successful. This is to (pardon me) light a fire under your ass and get you moving so that there'll still be amateur radio in the years ahead.

Keep up the good work with *73*. You may not have all the answers, but you raise the right questions. The League's LRPC is a hollow toothless group set up to quell the increasing dissatisfaction brewing in the amateur ranks. The time has come to stop talking and take positive action, and you're the man to lead the way. Best wishes for your continued success.

Scott Liebling WA3OXG
Baltimore MD

NEUTRAL

I have often felt that *73* lacked a rallying cry, a slogan if you will, an eye-catching, rousing phrase with an impact—words that would instantaneously impart to anyone picking up a copy of *73* the thrust and dynamic spirit of the magazine and its editor/publisher.

CQ states, on its cover, *"Serving Amateur Radio Since 1945"*—not much there!

QST says, *"Devoted Entirely To Amateur Radio"*—pretty bland!

How fitting it would be to see the cover of *73*, alternatively the vacant topside space of your editorial page, reflect the credo which I believe best exemplifies *73* and Wayne's personal stance in the field of ham radio: *"Neutral in nothing affecting the destiny of amateur radio."*

If that doesn't say it all, I don't know what does, Wayne! It would be interesting to determine how it strikes your staff.

Anyway, it's yours to do with as you wish. . .you may even desire to have it inscribed on your headstone when and if you ever depart this mortal sphere!

All the very best, Wayne, and please continue to be non-neutral (actually, I have no fear that you will ever change). I do enjoy receiving *73* over here and have a ready recollection of your visit to Frankfurt several years ago.

Burt Hubbs DJ0KQ
Frankfurt, Germany

LONELY

I got a brand-new CB rig and converted it to ten meters, using the "*73* band plan," just as suggested in the magazine.

Three weeks have passed and I have spent hours in consultation with this little box and its attendant power supply. My fingers are worn to the bone, going back and forth, up and down the forty positions, seeking a signal . . . some kind of noise . . . a voice from the past, perhaps . . . even an old, much-used cuss-word from the CB band would delight me! I can report nothing! Though the job checks out perfectly with the meter, I'm wondering if I'm even within the ten-meter band.

Considering the fact that there must be hundreds of amateurs who are suffering from the same malady, would you try to scare about two or three dozen down our way so that we might achieve just one contact and make our efforts worthwhile? You have no idea how lonely it's been these last weeks!

Dean Sturm K8CYW
Huntington WV

NIGERIA

Amateur operation here in Nigeria is now picking up and more stations are getting on each month, including even some activity on SSTV, so before long Nigeria should be one of the not-so-rare countries on the bands. Some calls heard on the bands have other prefixes than the old 5N2; now you might hear anything from 5N0 through 5N9, depending on which zone the station is in; the zones are divided among the 19 states that comprise the Federal Republic of Nigeria.

Richard Fitzgerald
WA5UTF/5N4
Lagos, Nigeria

Looking *West*

from page 10

gave the trade name Betamax. The first Betamax units (SL-7200 series) were also one-hour time limit machines like their big brother the U-Matic, but tape cost was less than half as much. Slowly but surely the Betamax caught on and began to spread into many American homes.

The one-hour time limit was still a drawback, however, until in late 1977 RCA and a number of other manufacturers announced that they also would be entering the home video recording market with machines utilizing the VHS recording format. VHS, which stands for Video Home System, is also cartridge format, but it has the added advantage of up to four hours record-play time. Unfortunately, Beta and VHS cartridges differ in size and are not interchangeable. Most VHS machines are two-speed affairs that record two hours at full speed or four hours at half speed, with some reduction in overall resolution at the reduced speed.

Not to be left out in the cold, manufacturers committed to the Beta format countered by introducing dual-speed and half-speed machines that gave up to two hours record-play on a one-hour tape cassette and then introduced a 1½-hour tape that would give up to three hours at half speed (or "X2" as it is called). Again, the Beta vs. VHS race was on with VHS appearing to be the eventual winner.

(A few weeks ago I read in one of the trade journals that Toshiba has developed an "Up To 6-Hour Beta Format Machine," and with this occurrence, the outcome of the race for the consumer dollar is anyone's guess. However, this should not keep you from obtaining a machine of your choice if you desire one.)

Regardless of which system is the eventual winner in the race to become the national standard—if, indeed, there ever is a winner or a national standard established—it's safe to say that both the Beta and VHS formats will be with us for a long, long time. Tapes, both blank and prerecorded, are in abundance for both formats, and both systems perform admirably. I went with Beta because I happen to like the machine and the results I get, but you should not judge by this. Judge for yourself, based upon your personal tastes and needs. I will tell you that having a home videocassette recorder is well within the pocketbook of most people these days. Even *73* writers.

Suppose you, yourself, have what you feel to be a good amateur-radio-related presentation. You have given it locally and now other clubs or conventions far distant want you but cannot afford to pay for transportation and/or lodging. You want to go, but with gasoline now over a dollar a gallon, you are forced to decline. If only there were some other way!

And indeed there is, if you or someone you know happens to own a home videocassette recorder and a camera. Even if not, they can be rented. Add a few lights and a friend to act as cameraperson and you literally have your own mini-production company. If you have the equipment or can get your hands on it, your cost for the raw tape will be between $14 and $20.

You do not have to be an expert at producing your own "educational spectacular." Suppose you make a mistake halfway through. If the machine you are using has good lockup, you might be able to rewind back past your boo-boo and pick up the presentation from that point. Or, you could simply rewind all the way and begin again. It's up to you and depends upon the level of perfection you are seeking. That's the nice thing about tape. Mistakes cost only time.

Video recording is here to stay and what can be done with it will amaze you once you get into it. Each day new ideas pop up in which a videocassette recorder can play an important part. Who knows; someday in the future this magazine may come to you in the form of a videocassette. Imagine having Wayne Green in your living room reading his famous editorials to you!

THE TEXAS REPORT

Walt Wiederhold W5OGZ is the Texas State Coordination Chairman for the Texas VHF-FM Society. In the current issue of that organization's newsletter, Walt relates the following:

"This quarter has seen a net increase of eight repeaters in the state. Of course, this is a gradual change and not something that takes place overnight. Many of the new repeaters have been in the planning stage for some time and have just been put on the air.

"We are always glad to see more repeaters since they serve such a good purpose in the amateur world today. But don't forget that other forms of communication work very well in the amateur bands and they should be used where possible. Working DX through a repeater doesn't really prove your rig as much as working the other station direct would. So you have a good antenna and you find that you can work across the state line into a repeater over there which is 200 feet in the air with quite a bit of power. Wouldn't it be better to use your ingenuity to talk to a station like your own without the use of the repeater?

"Every band from six meters through 1296 MHz can be used for repeaters and also for these other forms of communications. It would be most gratifying to see a big increase in activity in the 220 and 450 MHz bands and also in the higher frequency bands. We are not saying that 1296 is the top . . . just that it seems like the top right now just as six and two meters did at one time. Greater things are coming, so how about getting in on the ground floor by using your talents to explore the uses of the higher frequency bands? Didn't mean to leave out ten meters either, but it's a special band in itself.

"Wichita Falls, on April 10th, proved the need for emergency-powered repeaters. We hope a lot of operators will try to provide such power for their repeaters so they will be more likely to stay in operation when the need arises. Several repeaters in the state already have emergency power. Tornadoes can strike anywhere. Does your repeater have auxiliary power? Even the club generator, usually used on field day, can be used for that purpose. Think about it a bit and make some needed improvements in your setup."

TO THE FUTURE DEPARTMENT

I wish to close this month with the following thought from Jean AJ6Y which appeared in the June, 1979, issue of *Key-Klix*, the newsletter of the Santa Barbara Amateur Radio Club. With the World Administrative Radio Conference now upon us, I feel that the following is truly apropos.

"Many things have happened since Samuel F. B. Morse on Friday, May 24th, 1844, at 8:45 am sent the first telegraph message to Alfred Vail over the wires for a distance of forty miles. If each one of you will look back over your experience with radio and Morse code, you will see what I mean. The technology of this event was far beyond the scope of most people of the time and the event itself was probably viewed in the same way that you and I react to pictures from Jupiter. I keep wondering about the future of amateur radio and what the communication picture will look like in the year 2000 . . ."

As we remember the achievements of Samuel F. B. Morse, Thomas Edison, and others, so should we remember the foregoing from AJ6Y. In a very few words, Jean has said it all.

Review

INDEX TO HOW TO DO IT INFORMATION

(1978 edition, Mary Lou Lathrop and Norman M. Lathrop, Norman Lathrop Enterprises, PO Box 198, Wooster OH 44691; 161pages; $10.00 + $1.16 shipping)

How many hobbies do you have? Mine number at least seven at the moment: microcomputing, photography, electronics, astronomy, scale modeling, camping, and (of course) amateur radio. These diverse avocations have one thing in common. They are do-it-yourself hobbies—active, rather than passive, ways of using leisure time.

Recently, I discovered a very useful book for us do-it-yourself types. It's called the *Index to How To Do It Information*. This book indexes magazine articles from 52 different publications, ranging from *McCall's* to *Scientific American*, and *National Carvers Review* to *Kilobaud Microcomputing*. That's quite a range.

More than 1,000 subject areas have been used to catalog the magazine articles, making it easy to zero in on specific items of interest. Subject areas are liberally cross-referenced, so you'll often find yourself looking for more information under headings you might otherwise have missed. When you look up "Radio," for instance, you are advised to check no less than 13 other subject headings for further information.

The *Index* is very strong on electronics, photography, and all types of crafts. At present, articles from the ham magazines are not included, but new publications are being added to the *Index* every year. Naturally, this book is useless unless you have access to the publications it references. However, if your local library has a good periodicals collection, ten dollars invested in the *Index to How To Do It Information* would be money well spent.

Jeff DeTray WB8BTH
Assistant Publisher

DX

from page 12

the last to operate there several years ago) is talking about maybe trying again next summer, and a G-land group has high hopes for an operation in the immediate future. Work 'em first . . . etc.

Hans ST0RK has a new linear and TH3 beam courtesy of the W7PHO group. Look for Hans on Sundays around 21320 or 28600 kHz and during the week on 14225 kHz between 1500Z and 1600Z.

Bob T2AAA is on 14225 kHz almost daily from 1200Z.

A group of UA0 types will be signing U0Y from Tana Tuva in rare zone 23 from now through November 20th.

Congratulations to Dan WD6CDU/KH9 for a first-rate performance from Wake Island. Dan's debut into DXpeditioning was a model of good operating practices.

OH2BH had to cancel his Mt. Athos plans due to a prior commitment with the stork.

DJ9ZB's *QSL Managers Directory* is updated quarterly and presently contains some 3900 listings. Price is $5.00 and it is available directly from DJ9ZB.

Lou 3A2HB keeps regular Tuesday skeds with N1ACW and W4LRI on 14240 kHz at 2000Z.

Father Moran 9N1MM is down to 100 Watts since his linear died. Someone advised him to tune for maximum smoke. That's what he did and that's what he got.

During the period October 10 to November 10, Dutch amateurs will be allowed to add a "5" to their callsign, signifying 50 years of amateur radio in the Netherlands. PA0s will become PA50s, PA1s become PA51s, etc.

Slim was back at his original QTH recently again signing 8X8A from Cray Island. Some may remember when Slim signed 1Z4NG, lined up a QSL manager, and then actually forwarded his logs and a stack of QSL cards to the manager. Everything was going fine until the ARRL bounced all the cards back.

Jim Walter WA4GWD, who recently signed VP2VFD, dropped us a note to let everyone know that the correct QSL route is 249 Clearlake Drive W., Nashville TN 37217.

New officers of the Northern California DX Club are President—Ted Davis W6BJS, VP—Ron Rasmussen K6OP, Secretary—Joe Dillow W6UR, and Treasurer—Dave Palmer W6PHF. Directors are Charles Kump W6ZYC, Hal Godfrey N6AN, and Merle Parten K6DC.

Gordon Orelli K1OR has worked WAZ from five different QTHs. Working 3B8DA finished his latest one off from Brazil. Wonder if anyone else has worked WAZ from more than two locations.

ZS4MG reports never receiving any H5AA logs, so he can't fill the many QSL requests.

Has anyone received a bona fide card from LU3ZY or 5R8AL?

ARRL membership at the end of May totaled 167,541, up from 165,163 at the end of January. Total amateur licenses came to 363,820, including 66,363 Novices, 69,162 Technicians, 120,903 Generals, 84,181 Advanceds, and 23,211 Extras.

For the last couple of years, there has been a persistent jamming of DX activities in Europe. Finally fed up with the constant interference, a group of irate European DXers set out with RDFs and soon identified the culprit as an EI type. Swedish authorities have forwarded complaints through official channels and some Swedish amateurs have openly identified the EI station in on-the-air QSOs in a vain attempt at clearing up the problem. SM5BBC was recently discussing the problem on the air and a few days later ZA2BC showed up giving SM5BBC as the QSL route. Slim seems to be not only persistent, but vindictive as well.

The correct QSL address for all of K5VT's operations including K5VT/5T5, /6W8, /5H3, SV5, and XT2AE, 9G1LM, and TY9ER is c/o W2TK, 366 Rutherford Avenue, Lyndhurst NJ 07071.

Although it may all be straightened out by the time this column appears in print, as of early August the TH8JM problem was still very much up in the air with those holding QSLs wondering if they would ever be accepted by the DXCC desk. The origin of the TH8 prefix dates back some ten years when the American Ambassador there was issued a TH8 license with the stipulation that the Ambassador could issue TH8 licenses to any members of the Embassy delegation, but not to visitors. Since this privilege was never rescinded and since TH8JM is an Embassy communications officer and therefore a member of the Embassy delegation, it would seem on the surface that everything is on the up and up and there would be no problems in getting the confirmations accepted for DXCC credit. Of course, life for the deserving is never easy and problems have developed somewhere along the line. Fortunately, another license, TL8JM, has been issued and the necessary documentation forwarded to those hard-to-please guardians of the eternal DX flame in Newington. The Delta DX Association has forwarded a new Yaesu rig, and, if everything works out, before long TL8 will probably be just more garden-variety DX.

NOVICE CORNER

Never, but never, go to your local post office and purchase IRCs. The best source for IRCs at a reasonable price is one of the more active QSL managers. They receive IRCs from overseas stations and are usually quite happy to unload them in bundles of 25 or so for something in the neighborhood of a quarter each. An especially good source is the QSL manager or managers of a recent DXpedition to some exotic location. They receive literally thousands of IRCs and generally announce their availability once the QSLing has been taken care of. Once the announcement has been made, they disappear in short order, so it is important to plan ahead and get your request in early.

OKINO TORISHIMA

We just received two photo QSLs from the recent JF1IST/7J1 DXpedition to Okino Torishima and they are fantastic! One shows a wide view of the island(?) with the operating platform jutting up from the sea. The other one has a close-up shot of the tent on top of the operating platform. Hopefully, we will have some color shots of this one-man operation for next month's column.

WEST COAST DX BULLETIN

With honest regret, we report that the weekly *West Coast DX Bulletin* ceased publication with the July 18th issue. The *Bulletin* was a one-man effort by Hugh Cassidy WA6AUD. During the all-too-short eleven-year life of the *Bulletin*, Cass somehow managed to never miss a week in bringing us all the latest DX news. Much of what you read in this column came straight from the *Bulletin*'s multi-colored, hand-typed pages. Thanks a lot, Cass; it was fun.

DX RIDDLE

Someone finally sent in the correct answer to our DX Riddle—which three DXCC countries share the same prefix but are located within separate continental boundaries? Actually, there turned out to be more than one correct answer. Will Roberts AA4NC and Tim Fanus WB3DNA guessed KA1 USA, KA1 Ogasawara, and KA1 Minami Torishima. Rick Cole WD4CTA was the only one to come up with the answer we had in mind: HK0 Mai Pelo, HK0 Bajo Nuevo, and HK0 Serrana Bank. Congratulations, guys, and thanks to everyone who took the time to send in an answer.

That's about all there is for this month. Remember, pictures and DX news are always welcome.

Thanks for much of the preceding to JA1NRH, WD4CTA, AA4NC, WB3DNA, WD9COA, WA4PRU, WA1ZXF, N8AJA, VE2FIT, the LIDXA *Bulletin*, *Worldradio News*, and, for the last time, the *West Coast DX Bulletin*.

Ham Help

I wish to purchase, in any condition, a BC-314. I will pay a fair price plus shipping costs.

Kenneth Hunt
6519 Valhalla Ave.
Klamath Falls OR 97601

I need operating manuals with schematics for a Hallicrafters SX-40B receiver and an Eico 720 transmitter. I will pay in advance by money order for originals or good copies.

George E. Davidson KA4FNB
5290 Joan of Arc Place
College Park GA 30349

An Icom 701 international users club is now operational. Send an SASE for details.

Rob Pohorence N8RT
9600 Kickapoo Pass
Streetsboro OH 44240

I'm looking for information on how to combine my Superboard II from OSI with ham radio for RTTY, Morse, and ASCII send and receive functions. Can anyone help?

C. B. Smith VE3IEN
33 Todd Road
Agincourt, Ontario
Canada M1S 2K2

I have a Midland model 13-895 SSB Citizens Band radio, and wish to convert it to 10 meters. I have not as yet seen an article on this particular rig. Can anyone help? I recently picked up my General ticket and I am curious as to what is happening on 10.

Info

nagging, and other negative means to try to force him to do what you want, you'll be as successful as the FCC was in trying to force hams to get the Extra class license. They flatly refused to do it until the FCC came up with some rewards instead of punishment.

There is one feature of many ARRL conventions that irritates the hell out of me. This is the SWOOP ridiculousness. I think that stands for the Suffering Wives of Operating Personnel or some such foolishness. One high point of these SWOOP meetings is the destruction of a piece of ham equipment by the wives . . . taking out their frustrations and resentments on equipment. Disgusting.

Won't you be happier if your husband is happy? So all you have to do is look at the good points and work out ways to have him enjoy some of the things you want to do, too.

Now, OMs . . . it is really important for you to come to terms with your wife. Explain to her that your love of your job or your love of amateur radio are not taking away from your love of her. Your progress in your job is a reflection of her help . . . and your fun and relaxation with amateur radio are an important part of your life. It is important that you be considerate and fair. You can't really expect her to enjoy being dragged to a hamfest and made to look at a hundred booths full of ham gear and parts any more than you'd probably want to go to a knitting show. You'll be happier in the long run if you go to a hamfest and give her the car and a credit card . . . and tell her how to find the big shopping mall. She might get you a present. She also might put you in hock.

Despite the fun you have with amateur radio, you still have responsibilities to the world . . . to do a good job of work . . . and to keep your wife and family happy. It's tough to have dinner with another ham and not sit talking ham talk all night, so keep this in mind and maybe get your wives together at the next table for their dinner so they can talk, too. In the long run, you'll get a lot more out of ham radio if you have a good working relationship with your wife about it.

MICRO COUNTRIES

A chap who specializes in getting information on very small and often virtually unknown countries called the other day. I think I convinced him to write an article which should be of intense interest to DXers . . . and even more to hamming activity from there, more's the pity. And Sealand is still virgin territory. Do I have to start working on these things myself? I have plenty to do without leading another DXpedition somewhere.

He mentioned that as far as he knows, Miller's St. Brandon's Island is completely mythical. He also suggested a new one which has never been done by a DXpedition . . . an easy-to-reach island in the Mediterranean. Anyone interested in putting a new one on the air? If I tell you the name, I know damned well that a bunch will pop off to there and I'll get left behind. I've had that happen a couple of times. I'll be cagier this time.

FIFTH ANNUAL HAM WORKSHOP JANUARY 12-19

Members of the ham industry get together each January in Aspen, Colorado, for a week of skiing and workshops on ham topics. With the growth of amateur radio stagnating and the sales of ham gear along with it, both manufacturers and dealers will be discussing plans for getting the hobby going again.

Some of the problem is obviously the drop in interest in CB radio, which had gotten thousands of newcomers interested in radio communications each year. Another has been the worry over what might happen at WARC. Still another has been inflation and the recession. One of the workshops will be devoted to discussing ideas for reviving interest in hamming.

Those firms in the consumer electronics business may want to go first to Las Vegas for the Winter Consumer Electronic Show, January 5-9. Then, for those with a strong stomach, there is SAROC, January 10-12. One day of that is more than enough, if they have the same number of exhibitors as two years ago and the same exciting program. If enough people want to fly from Las Vegas to Aspen, we could charter a special plane.

There are workshops planned on dealer financing, mail-order success, how to get over $50,000 in free advertising, what the ham gear of 1983 will be like, how the ARRL turned the American ham industry over to Japan, how to design and write ads which will sell like crazy, where to run the ads, what to do about the WARC results, etc. It should be understood that the workshops will not interfere with skiing.

The host hotel this time will be the Limelight, which is one block from downtown Aspen. You won't need a car. The organizing committee for the Ham Workshop checked out Vail last winter, just to make sure that it was not as good as Aspen. It wasn't, despite its having a McDonald's and a Burger King. Aspen has more good restaurants per square mile than any other town in the world . . . and some of them are incredible. I've got to start dieting, to be ready for that.

You are on your own as far as getting to and from Aspen is concerned . . . and also hotel reservations. Please let Sherry know (c/o *73 Magazine*, Peterborough NH 03458) so she will include you in the meeting room plans and dinner reservations. There is no charge for the event again this year . . . except for the costs of Aspen, which are formidable. Any manufacturer, dealer, or even a ham seriously interested in both skiing and the progress of amateur radio is invited. We have about a dozen signed up so far . . . including Chuck Martin WA1KPS of Tufts Electronics.

It will be fun and might be money well spent if you get one good idea which bears fruit in business.

JULY WINNER

July's most popular article, as voted by our readers with their Reader Service card ballots, was James Wyma WA7DPX's "So You Want to Raise a Tower." A check for $100 is on its way to him.

LETTERS

INTRUDER WATCH

Wells R. Chapin W8GI
Byron H. Kretzman W2JTP
Steve Baumrucker WD4MKQ

I refer to W2JTP's comment to W8GI in the August, 1979, Letters section regarding the ARRL and the Intruder Watch.

I do not think that you are correct about the ARRL coining the word "Intruder" and establishing the first Intruder watch —well, not exactly. I believe from the RSGB's *Radio Communications* publication and other sources that the "Intruder Watch" was first formed in Britain and was followed, somewhere around 1965 in the USA, as one of many such watches organized under the IARU around the world. However, the thousands of reports monthly via the ARRL and massive help from the FCC Monitoring Branch and Treaty Branch have brought about many improvements, but not in every country. It was my estimate some time ago that about 80% of the intruders (disregarding assigned sharing of the 40- and 80-meter bands by normal broadcasting) were Russian, 10% Chinese, with the remaining 10% being miscellaneous intentional or accidental occupants.

My records were searched over the past several years, but none of you was listed in the "roster" of USA and Canadian "Intruder Watchers." The ARRL could not begin to handle the massive problem of intruders using paid help in Newington, but they do make an effort (particularly before the present "bind" in Newington regarding manpower) to keep up with the IARU monitoring system.

Within that system, and sometimes a little outside of it, we have eliminated numbers of intruders—but few Russians or Chinese. Personal contact also has been helpful, including designing antenna traps for distant broadcasting stations, getting some moved to proper allocations, and so on. BBC Johore (Far-East Relay) had a strong harmonic on 14240 kHz; with the help of the British watch, BBC designed a new antenna trap for the second harmonic of 7120 kHz, then wrote to me saying that they had reduced the harmonic to −76.9 dB, asking me to check it (it had completely disappeared) and to inform them informally if it ever returns. Many such improvements have been brought about.

But the manpower to listen to cassettes of Russian fishing boats on 3550/3650 kHz and the like just wasn't available at Newington, which already had received many, many identifications, calls, times, frequencies, dates, and records of alerting FCC Monitoring to confirm this intrusion of 80 meters.

If you look into the *ARRL License Manual*, you will find a "Geneva Amateur Allocations Summary" taken from their big allband "Allocations" chart. This shows that mobile services share the 3500-3800-kHz segment of the 80-meter band in Region 1 (Europe-Africa-Siberia-Middle East), 3500-4000 in Region 2 (North and South America), and 3500-3900 in Region 3 (rest of the world). So, the Russian fishing fleet was legal, at least when it was in Region 1 waters. If the FCC was able to find some point on which to base a complaint, my guess is that they *did* take such action, usually by an ITU-standardized cable or radiogram. So, what more could we do, especially with the frequency being legally shared with the mobile service in each region?

Until recently, I averaged 95 long-distance calls to FCC Monitoring a month to alert them to intruders on the air at the time subject to "treaty" action—with the phone expense paid by the ARRL. Subsequently, I found that I was overloading the monitoring system of the country and cut it down largely to those transmissions with a particularly good reason to complain and get action, such as spurious families in the bands, whether the cause is inside or outside. Remember that the USSR has the special right to use 14250/14350 for "fixed" (point-to-point) service, and also the ITU allocations have a footnote exempting "military" everywhere. I lay off of legal broadcasting like VOA and others, though recently I did try to point out to VOA that by the USA giving up Okinawa and VOA moving to the Philippines, their Chinese service antennas now practically point at the USA east coast, which ought to be protected from receiving "harmful levels" of interference. I informed VOA of the specific cases in Europe and Africa where sites are used which involve antennas which, in addition to covering the service area, are incidentally aimed at Region 2 and cause harmful interference in North and South America. Also, we have complained about Deutsche Welle broadcasting on 3995 kHz afternoons and evenings in German to Latin America, which is contrary to ITU regulations.

But there are hundreds upon hundreds of individual cases of intruders on amateur frequencies. I have been preparing reports on some 400 to 450 different frequencies (mainly 14 MHz, lately) a month, with many reports listing as many as 25 additional date/time groups of "sightings" of the same signal. The ARRL has had to sort and ship by air up to about 4000 report forms a month to G3PSM, who produces a 20-22 page *Intruder Monthly Summary*. This goes to the ITU in multiple copies, to VOA and others, and to many Intruder Watchers around the world requesting action on *their* country's responsibilities in the summary, and so on. We especially need more Intruder Watchers from the Caribbean and Central and South America, now coordinated by K6DL, who has taken over the Region 2 work so that I can write letters such as this!

Let's give more of the facts about what is going on, what is legal and what is not, who is doing what, and what can be done. But let us not repeat WD4MKQ's boo-boo of doing illegal things ourselves and becoming intruders, too, by following that suggestion of trying to jam the intruders. Often that harms other amateurs as much as, or more than, the intruder. We have had little apparent success over the years on the part of those, especially in other countries, who are willing to jam the radar pulse, but it is very unlikely to be more than a happenstance, if it seems to work.

Remember that if A and B are intruders, and we may know the direction to A, which we hear, we still do not do any harm unless we jam the receiver at B, who is in an unkown direction usually. Not only that, but because of the geographical problem, it is highly likely that the band is not even open to the receiving point, B, from the USA. Two amateurs on CW did, however, get on an Arabic phone net in the 14-MHz CW band, call "CQ Intruder Watch," and raise other stations, who proceeded to discuss the interference; when the phone net moved, more "CQ IW" calls appeared on the new frequency, and finally the intruders got out of the amateur band and stayed out. But intentional jamming of communications draws very severe penalties under FCC Regulations, Sec. 97.125: "Interference—No licensed radio operator shall willfully or maliciously interfere with or cause interference to any radiocommunication or signal."

Let us divert our efforts to legal things that we can do to assist in this work, worldwide, and hope that our efforts, at least in part, may minimize the increase of such interference from intruders. I personally hope that my last 14 years of nearly full-time IW and OO work, to the exclusion of most other activities, has not been in vain.

E. H. Conklin K6KA
La Canada CA

RIGHT ON!

I read your August, 1979, editorial with great interest. I agree that Mr. Booth's attitude towards the FCC's commissioners was indeed wrong. As a sales representative, I know your method is the most successful.

I would add, in closing, that this was the first issue of *73* that I have read in one year as a ham. I read your editorial with fervor, and I can honestly say that that never happens when I read *QST*. Right on!

John Cerniglia N9AGB
Madison WI

2M RTTY

In reference to Wayne's editorial concerning crossband repeaters (August, 1979, p. 6), I might pass on a unique situation that occurred not long ago.

On January 16, 1979, quite a few local 2-meter RTTY buffs were astounded to see in print, from autostart, that a KH6 had been on the repeater (146.10/.70) calling CQ RTTY! A little further down the paper, they also saw that two stations actually worked him. After a previous QSO on 20-meter RTTY and a short lesson in how to access, Tony KH6JEO from Makakilo, Hawaii, transmitted at 14.083 MHz. My station, acting as a manual repeater, retransmitted his signal onto the input of the 2-meter repeater via my ST-6 terminal system and a few routing switches (the same way we retransmit W1AW RTTY bulletins onto the RTTY repeater).

The replying signals, originating on two meters, were reversed, outputting onto twenty meters, and, therefore, became perhaps the first "crossband,

CONGRESSMAN TO HELP THE AMATEUR COMMUNITY CONQUER MALICIOUS INTERFERENCE

"Amateur radio is a service, not just a hobby, and must be protected." These were the words of Congressman James Corman, a democrat from Van Nuys, California, spoken in an exclusive interview with this reporter on Monday, August 29, 1979, at the congressman's San Fernando Valley office.

I met with Congressman Corman after it had been reported that he had shown an interest in helping the amateur community to clean house. I wanted to know exactly where he stood on certain issues and thought you might also be interested. In early August, Congressman Corman met with ARRL Southwestern Division Director Jay Holliday W6EJJ and Special Assistant Director Joe Merdler N6AHU to discuss the growing malicious interference and regulatory violation problems. At that time, he voiced strong support for the cleanup task that Jay and Joe had started; many felt that his was the type of help most needed now. It was through Joe Merdler (who also serves as our legal correspondent for the Westlink Amateur Radio News) that the interview with Congressman Corman was arranged.

From the start, Congressman Corman made it clear that this would be a coordinated effort on his part. He stated, "Four hundred thirty-five congressmen going in different directions will accomplish nothing." He intends to meet in Washington with ARRL General Council Bob Booth, along with Joe Merdler. There they will begin attacking the whole problem, with the support of the ARRL. He also stated that he intends to find out the reason why the FCC has failed to act in the case of Scott Lookholder WB6LHB, who was convicted of malicious interference earlier this year. The congressman concluded by stating that the 1st Amendment does not give any person the right to use obscene language or in any other way maliciously interfere with the legitimate use of the airwaves.

THE CREATION OF "NATIONTIE '80" DEPARTMENT

In last month's column we began discussing what might be accomplished were a fair number of already existing two-meter open repeaters linked together to provide coast-to-coast, border-to-border amateur relay communication. We suggested that you might want to try some interlinking experiments with other repeaters in your general area that are outside your normal system coverage. In essence, we hope that we have whetted your appetite for even bigger and better things. If we have, then I suggest you pay special attention to this column for the next couple of months because the creation of an open national intertie will be the center of attraction for some time to come.

If you have never operated through a repeater intertie, you are really missing something. When you spend a lot of your operating time on local repeaters, it is easy to forget that there are many people out there who, while still living in your general area, may have dramatically different lifestyles than yours. Most HF operators, especially those who enjoy chewing the rag, can easily relate to this. Through long-winded QSOing, amateurs in different areas learn about each other through the interaction that is the classic QSO. It's sad, but true, that this is rarely the case for VHF repeater operation. Most amateurs, even those with the most sophisticated equipment, seem to wind up as habitual users on one or two local repeaters where they become part of that system's "in" crowd.

There is another aspect of repeater operation that tends to be a limiting factor in this area. On many repeaters, holding anything more than a quick "hello, how are you, good-bye" QSO is a taboo, enforced by a device known as a "blab-off timer." I never could see the strict rules barring normal QSOs on repeaters, because "someday an emergency might arise and the repeater will be busy." Believe me, if I ever have an emergency and a repeater is busy, I will find a way to be heard! It is, however, such regulations that tend to discourage true interaction by amateurs. True, two people living six blocks away from each other should not hold their QSOs through a repeater sixty miles away just to have an audience for their rhetoric. Such regulations do tend to discourage this type of activity; however, the same rules also tend to stifle meaningful communication. If necessary, a telephone call to an offender can usually solve any problem quite quickly.

While we cannot and will not attempt to change the operating rules on a repeater belonging to someone else, we will suggest that one of the objectives of Nationtie '80 must be to develop true lines of intercommunication and interaction among those amateurs who desire it.

Another objective must be the "advancement of the state of the art," or, more simply, "scientific achievement." There are two aspects of science, research and the application of what has been learned. Research is pointless if never applied. I say this because in many ways we will be doing nothing really new. Interlinks of varying sizes have existed for years, but their accessibility has been limited to a select few. These limited operations can be the cornerstone of something bigger and better, available to any amateur who may wish to utilize it. The technology already exists and is waiting for us to develop and utilize it.

Last month, we described a simple linking experiment that might best be termed "haphazard local linking." If we are to build a national intertie, we must have a definite objective. The obvious objective is to find a way for point A (Los Angeles, perhaps) to converse with point G (New York, perhaps) even though they are well outside what is considered normal VHF communications range. They must have their signals relayed several times. Now, if at each of the relay points you place input/output ports (local relay devices that can talk with any other relay point as well as with both terminal points), you will have an interactive radio intertie. There are various ways in which such linking can be accomplished, and we will now touch upon each.

For occasional links over long distances, the most common form of linking is accomplished via the long-distance telephone call—along with its long-distance toll rates. If the two systems involved in such a link have autopatch facilities or telephone accessibility for command purposes, the task of completing such a link is simple. If I, as repeater A, want to link with repeater G, I simply dial their dial-in number. This has been the basis of many long-distance links reported in this column over the years. The major drawback of this method is its cost, and for that reason it has never really become popular.

A second method involves the use of crossband, remote-base operation from spectrum considered local to one of our HF bands, which provides for longer-distance propagation. Many links have already been accomplished by cross-linking from VHF/UHF to ten-meter FM. However, ten meters is far from the ideal band in which to develop an interlink system that will function with reliability on a day-to-day basis. This is due to the somewhat erratic nature of long-haul ten-meter propagation. Actually, our most crowded HF band, twenty meters, probably offers the best potential for such an operation by crossband/cross-mode (FM to SSB) remoting. Again, this is far from an ideal situation, even though 14.285 MHz has become the de facto HF remote downlink DX frequency, much to the chagrin of many other spectrum users who do not appreciate hearing SSB signals with built-in squelch crashes! Though far more predictable and reliable in its propagation characteristics, the crowding one finds across the twenty-meter spectrum precludes its use on a regular basis for the establishment of an ongoing intertie operation.

This brings us to our third and probably most cost-effective method of interlinking, that of total radio relay. If we were to start from scratch to build a coast-to-coast intertie using multi-hop radio relay techniques, there would be very few able to foot the bill. However, with over 3,000 operational open two-meter repeaters throughout the country already, the cost factor looks a little more positive. Most of what is needed is already in place. The equipment sits atop tall buildings, towers, and mountaintops, and is already in day-to-day operation. The cost of interlinking is thereby minimal, since only one receiver and one transmitter need to be added to any existing system in order to interlink with any other system, and only two receivers and two transmitters are needed for it to become an interactive radio-relay device as part of a large intertie. (This is assuming that the existing two-meter facilities will take on a second job as the local access port to such a national system.) If the 220 band were used for the actual linking, then, at today's current market prices for new equipment, you are talking under $500 for the basic hardware (including your yagi-type antennas). You can get very elaborate and "go for broke," but that is neither necessary nor encouraged. If we keep sight of the old computer-industry adage of KISS (Keep It Simple, Stupid), we are far better off. The less complex we make it, the fewer headaches we will have in days to come.

Continued on page 194

The following are excerpts from unsolicited letters and registration cards received from owners of the new TEN-TEC OMNI transceiver.

"I sold a Yaesu to buy this and am very impressed" —WB5ULA

"My first QSO with OMNI-A was LA1SV on CW and second was EA8SK on SSB." —N2CC

"Excellent rig, just as advertised." —WB5TMD

"Very pleased with performance. QSK feature very slick." —WB0ELM

"This is my 5th TEN-TEC transceiver in less than 2 years. I loved them all and still have 3." —WB0VCA

"Through the years I have had complete Drake and Collins stations. I tried a 544 Digital and liked it the best so decided to purchase the 546 OMNI-D Digital." —WA4NFM

"Your OMNI is the best rig I have had in 20 years of haming." —K4IHI

"As a owner of Collins rig, your OMNI-D is the best." —K9JJL

"I already have an OMNI-A, 544 and a TRITON IV. You may ask why I own so many TEN-TEC rigs. In case there is a great RF famine, I want to be ready!" —WD4HCS

"You guys really know how to turn on an old timer!" —K8ELS

"Best operating & most conveniences of any transceiver I've ever used." —W6LZI

"I like CW. Compared OMNI against IC701 (rcvr) and OMNI won hands down. XYL WD6GSB really enjoys rig on SSB. Finds rig is very stable and digital readout accurate." —AC6B

"Have checked it out on both modes from "top band" (160) all the way to 29 MHz. Terrific!!!!" —W4DN

"Works well, parts layout and design much better for any possible servicing than other ham gear. The Japanese hybrid sets can't compare to TEN-TEC for audio. Audio reports excellent without special speech processors, etc., to distort the signal." —AG8K

"I have been using the S-Line over 15 yrs and never thought anything could outperform it. I got the biggest surprise and THRILLED with this OMNI-D even though I have been a ham since 1936." —KV4GD

"This must be the greatest. I've spent enough money on final tubes to almost pay for this." —KA4BIH

"This transceiver was recommended to me by old time hams (Xtras) whom I have known for 40 yrs. Has excellent break-in." —N6AVQ

"Best package job I've ever seen! First licensed 6AAV in 1926. Now in operation—a sweetheart!" —W7LUP

"From a 32V2/SX115 to an OMNI is a big step!" —K6YD

"Receiver prominent—transmitter likewise—working comfortable—pleasing design." —OE1FAA

"First new rig for me in 10 years but seems to be very good." —W5GBY

"The best transceiver I ever used or owned." —W3TS

"I wouldn't swap my OMNI for anything on the market, regardless of price." —WD0HTE

OMNI/SERIES B FEATURES

All solid-state; 160-10 meters; Broadband design; Standard 8-Pole 2.4 kHz Crystal Ladder I-F Filter + Optional 1.8 kHz SSB Filter & 0.5 kHz 8-Pole CW Filter; 3-Bandwidth Active Audio Filter; Choice of readout — OMNI-A (analog dial), OMNI-D (digital); **Built-in VOX and PTT, Selectable Break-in, Dual-Range Receiver Offset Tuning, Wide Overload Capabilities, Phone Patch Interface Jacks; Adjustable ALC; Adjustable Sidetone; Exceptional Sensitivity; 200 Watts INPUT; 100% Duty Cycle, Front Panel Microphone and Key Jacks; Zero-Beat Switch; "S"/SWR Meter; Dual Speakers; Plug-In Circuit Boards; Complete Shielding; Easier-to-use size:** 5¾"h x 14¼"w x 14"d; **Full Options:** Model 645 Keyer $85; Model 243 Remote VFO $139; Model 252MO matching AC power supply $139, Model 248 Noise Blanker $49, Model 217 500 Hz 8-Pole Crystal Ladder CW Filter $55, Model 218 1.8 kHz 8-Pole Crystal Ladder SSB Filter $55.

Model 545 Series B OMNI-A . . . $949
Model 546 Series B OMNI-D . . . $1119

RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

Not all keyboards are created equal. Depending upon what you are copying, ham RTTY, weather, or press, some are definitely more equal than others. With the interest shown in copying these other-than-ham RTTY signals, I thought it might be a good idea to review the keytops and symbols found on Teletype™ machines.

My Model 15 manual lists over a dozen sets of keytops used on various models of teleprinters. Most of the variation is in the uppercase, or FIGS, character set. The diversity can be simplified to three main groups, and I will call them, for the sake of simplicity, communications, weather, and press. These names derive from the principal function of each character set. A diagram of their relation is presented in Fig. 1. This shows the binary code, lowercase character, and uppercase character of each set.

The communications character set, also known as the American Communications keyboard, Teletype keyboard BS, 78932, or a few others, is what we commonly use on ham RTTY. It contains all the commonly-used uppercase characters with no unusual representations. Several variations of this keyboard are possible without too much conflict. Uppercase H has at least three assignments commonly found: #, STOP, and £ (British pound sign). For this reason, it is usually best to avoid sending very many uppercase Hs unless you know what the fellow has to whom you are sending. That STOP code, if hooked up, will disable his machine!

There is one other variation of the communications keyboard that bears mentioning: the so-called "Western Union" keyboard. This is identical except for one minor variation: The BELL is an uppercase J rather than an uppercase S. The S, in this case, is an apostrophe ('). These keyboards are common enough so that, frequently, when one wants to send a series of bells, JSJSJSJS is sent in uppercase. The printer prints '''' with a bell between each apostrophe, no matter which code is used.

The press code, also known as a Bell System, TWX, or fractions code (again, there are many other names and numbers), is notable for replacement of certain uppercase symbols with fractions. Now, you and I might not be too thrilled with having uppercase B a fraction instead of a question mark —imagine sending "HOW ARE YOU COPYING OVER THERE 5/8"—but if you are trying to send stock quotations and such, there is great value in being able to send each fraction in one byte rather than three. If this is what you have or is the only kind of machine you can get, don't despair; I'll touch on what you can do later.

Another interesting code is the weather code, with aliases of Weather Map Service, 89410, or 82750. Here, specialized symbols are used to give weather information that might otherwise take several characters or words. The utility of this for pilots and meteorologists is self-evident; for the rest of us, it means one more code to crack if we anticipate copying some of those interesting commercial stations. In Fig. 2, we look into just what those symbols mean and how to interpret them. These aviation weather reports provide a wealth of information, and Fig. 3 is derived from a US Department of Commerce example of how to decode them.

Now, if you don't have a particular set of symbols and you want to change, all is not lost. For Model 15s and 19s, it is rather simple. If you have, for example, a communications keyboard and you want to be able to copy weather code, the easiest way to change is to obtain an extra typing basket set up for the new codes. When you desire to shift codes, simply slide the old basket off and the new one on. Voilà!—a transformed machine. Return things to normal by shifting back. Extra typing baskets are available

Fig. 1.

Sky cover symbols are in ascending order. Figures preceding symbols are heights in hundreds of feet above station.

Sky cover symbols are:

- ○ Clear: Less than 0.1 sky cover
- ⊖ Scattered: 0.1 to less than 0.6 sky cover
- ⦶ Broken: 0.6 to 0.9 sky cover
- ● Overcast: More than 0.9 cover
- \- Thin (when prefixed to the above symbols)
- -X Partly obscured: 0.1 to less than 1.0 sky hidden by precipitation or obstruction to vision
- X Obscured: 1.0 sky hidden by precipitation or obstruction to vision

Fig. 2. Sky symbols on aviation weather reports.

CEILING:
Letter preceding height of layer identifies ceiling layer and indicates how ceiling height was obtained.
A = Aircraft B = Balloon E = Estimated M = Measured
R = Radar W = Indefinite V (suffix) = Variable Height

VISIBILITY:
Reported in statute miles and fractions (V = Variable)

WEATHER AND OBSTRUCTION TO VISION SYMBOLS:

A	Hail	IC	Ice Crystals	RW	Rain Showers
BD	Blowing Dust	IF	Ice Fog	S	Snow
BN	Blowing Sand	IP	Ice Pellets	SG	Snow Grains
BS	Blowing Snow	IPW	Ice Pellet Shwr	SW	Snow Showers
D	Dust	K	Smoke	T	Thunderstorms
F	Fog	L	Drizzle	T+	Severe T'storm
GF	Ground Fog	R	Rain	ZL	Freezing Drizzle
H	Haze			ZR	Freezing Rain

Precipitation: -- very light, - light, (no sign) moderate, + heavy

WIND
Direction in tens of degrees from north, speed in knots.
Example: 3627 = 360 degrees, 27 knots

RUNWAY VISUAL RANGE (RVR):
RVR is reported from some stations. Extreme values for ten minutes prior to observation are given in hundreds of feet. Runway identification precedes RVR report.

ALTIMETER SETTING:
The first figure of the actual altimeter setting is always omitted from the report.

CODED PILOT REPORTS:
Pilot reports (PIREPS) of clouds not visible from ground are coded with MSL height data preceding and/or following sky cover symbol to indicate cloud bases and/or tops, respectively.

Awards

Bill Gosney WB7BFK
2665 North 1250 East
Whidbey Island
Oak Harbor WA 98277

The response to the new *73* Awards Program announced in the September and October issues has been beyond all expectations. Award applications are being received from all over. Countless letters and telephone calls of support have been received, each claiming *73* now has one of the best award columns in existence. Let it be known that the readers are the ones to thank if this is true. All I can say is that we'll continue to strive for improvement.

Speaking of improvements, those of you who have your September copy of *73* might turn to pages 28 and 155, respectively, and make the following additions and changes. Completely overlooked was Jamaica (6Y5), which should have been included on the North American list. Looking at the list for Africa, transfer Yemen (4W) and People's Democratic Republic of Yemen (7O) over to the Asian listing. Also, it should be noted that the prefixes for each country shown do not represent the entire list of prefixes assigned to that country. Prefixes were shown merely for convenience.

By telephone, amateurs have asked why the Central American countries were identified as a South American claim. One such caller assumed our reasons were political. I assure you that this editor and this publication are not in the business of politics. The identity of Central America's countries was given to the South American listing merely to add balance to the overall program, nothing more. As for the contacts which are made to Antarctica, it was decided long ago that there would be 6 continental awards and contacts with Antarctica would count toward that country from which the callsign was issued. In other words, should I confirm contact with KC4AAA, I would be able to count that as USA toward my North American award. Likewise, should I work FB8YF on the polar cap, I would be able to count that as France in my bid for the European award.

And speaking of the WTW (Work the World) Award Program, there has been some confusion as to the award fee schedule. Let me try to explain it. In the WTW Award Program, there is a series of six continental awards which are in themselves quite an accomplishment. Each of these continental awards has a $3.00 award fee. Once the applicant has collected all six continental awards (European, African, Asian, South American, North American, and Oceanic), I (as custodian of the Awards Program) will request the New Hampshire offices to issue the seventh and ultimate WTW (Work the World) Award at no extra charge.

A week ago, I received a very impressive letter from one of our readers and I can't resist sharing parts of it with you. Hal Dennin AC3Q, who is the Chief of Police in Watsontown, Pennsylvania, wrote to inform me that he had accomplished in a little over one week something which takes most of us months and even years to achieve. To add insult to injury, Hal went on to claim that his feat was mastered operating QRP with his new Yaesu FT-7 into an ATB-34 triband beam. Claimed power . . . a mere 9 Watts output!

Well, have you guessed Hal's achievement? Not to keep you in further suspense, it appears that over 73 DX countries have been worked by Hal in only 10 days. Once confirmation is received, Hal will have qualified for the new 73 DX Country Club which was announced for the first time only a couple months ago. Hal's first contact was with LU3EEC on 28.750, and QSO number seventy-three came only 9 days later when he exchanged signal reports with 6W8FZ on 14.220 MHz.

Not one to give up, Hal proceeded past the 100 mark, having reached that goal on the thirteenth day, and is well on his way to 200 countries as you read this. As a matter of fact, Hal is so insistent on breaking records that he didn't even take the time to put his letter to me in the mailbox for fear he might miss a "new one" while away from the radio. Instead, his XYL was delegated the duty of putting the letter in the hands of the postman for delivery. Talk about dedication!

Neither Hal nor I know if this feat is a world record or not! I would think not too many (if any) could claim such an accomplishment, which, I might add, was completely independent of contest operation. Whether a world record or not, Hal deserves a hearty congratulations from us all . . . although at the same time I wonder if perhaps there shouldn't be a law against a crime like this.

Should any readers have a similar success story, why not drop us a line? Keep the details brief and straight to the point. Can you top Hal's new record?

The other day I received a letter from Vic Misek W1WCR, who represents the Top Band SSB Net. For those not familiar with the term, "top band" refers to those frequencies assigned the 160-meter segment of the radio spectrum. This band also has been referred to as the "gentleman's band" on occasion, largely due to the carefree, easygoing pace that appears so predominant on the band.

The Top Band SSB Net was formed in February, 1972, by a small group of operators composed of W2FWU, K2ANR, W2UBL, W2IMB, and W4NVN (formerly W1GJE). Over the

Microcomputer Interfacing

Christopher A. Titus
David G. Larsen
Peter R. Rony
Jonathan A. Titus

In the September column, we described several different seven-segment display interfaces as well as programs that can be used to display information on these displays. Here we shall describe the hardware and software required so that information can be entered into a microcomputer using a keyboard. There are a number of other general-purpose devices that can also be used to enter information into a microcomputer, including thumbwheel switches, analog-to-digital converters, thermostatic switches, and pressure switches. Of all the different input devices, keyboards are probably the most popular, simply because they are the most general-purpose input devices.

There are basically two types of keyboards that are used with microcomputers: *hardware-encoded* and *scanned*. A hardware-encoded keyboard, regardless of the type of keys used (metallic contact, Hall effect, capacitive), produces a unique code for each key. The code produced by each key may be ASCII, EBCDIC, binary, or BCD. The encoder section of the keyboard also produces some sort of *strobe pulse*, or logic level change, to indicate that a key is pressed.

Owing to recent advances in integrated circuit technology, the encoding logic may not only produce a unique key code, but may also transmit the code as an asynchronous serial character. A number of integrated circuits that can be used to encode individual key closures include the AY-5-3600 (General Instrument Corporation), the MM74C922 and MM74C923 (National Semiconductor Corporation), and the 8279 (Intel Corporation). A typical hardware-encoded keyboard interface is shown in Fig. 1. Because the hardware in the keyboard already encodes the key closures, the software required to sense a key closure and input a key code is very simple (see Fig. 2).

The first instruction in Fig. 2 inputs the strobe line, or flag, of the keyboard into the 8080's A register. If the flag is a logic zero, then no key in the keyboard is pressed. If the flag is a logic one, then a key is pressed. The ANI instruction sets all the bits in the A register to a logic zero with the exception of bit D0, which represents the state of the keyboard's flag. If the flag is a logic zero (no key is pressed), the A register will contain zero as a result of the ANI Instruction and the JZ (jump on zero) instruction to KEYIN will be executed. When a key is pressed, bit D0 of the A register will be a logic one after the first IN instruction is executed. As a result of the ANI instruction, the JZ to KEYIN will no longer be executed. Instead, the second IN instruction will be executed, which will cause the code for the key that is pressed to be read into the A register. *This instruction also causes the keyboard's flag to be cleared.* The keyboard flag must be cleared before the 8080 calls the KEYIN subroutine again, so that the 8080 does not sense that the same key is pressed. Remember, the key has only been pressed once. After the key code is input, the second ANI instruction sets the parity bit (D7) of the code to a logic zero. This means that the programs that call KEYIN can be used with keyboards that generate odd parity, even parity, or no parity.

Another type of keyboard that is often used with microcomputers is a *scanned* keyboard. This type of keyboard, like a multiplexed display, requires very little interface hardware but requires a large amount of software. Typically, scanned keyboards are used in calculators, microwave ovens, single-board microcomputers, and low-cost microcomputer-based games. The interface for a 16-key keyboard, arranged as four columns of four keys, is shown in Fig. 3. The software that causes the 8080 to scan the keyboard and generate a unique code for each key is listed in Fig. 4. This software has to perform many of the functions that were previously performed by the hardware-encoding logic. For instance, the software must (1) sense a key closure, (2) debounce the key closure, (3) determine which key is pressed, (4) generate a unique key code for the key that is pressed, (5) wait for the key to be released, and (6) debounce the key opening.

To detect if a key in the keyboard is pressed, the 8080 outputs a logic zero to one of the columns of keys and a logic one to the remaining columns. If one of the keys in the column that is being "driven" by the logic zero is pressed, the 8080 will input a logic zero and three logic ones into the A register. If no keys in the column being driven by the logic zero are pressed, the 8080 will input four logic ones. If this occurs, the 8080 will test another column of keys with a logic zero.

At the beginning of KEYSCN in Fig. 4, the D register is loaded with three, the code for the first key closure that can be detected. The B register is loaded with 11111110 (octal 376, hex FE), the first test pattern that will be output to the scanned keyboard. The test pattern is then moved to the A register where it is output to the keyboard. The same test pattern is then rotated once to the left, and the result, 11111101, is saved in the B register. The 8080 then inputs the row data of the keyboard and sets bits D7-D4 of the A register to zero (ANI 017). If no key in column A is pressed (keys 3, 7, 11, or 15), the A register will contain 017. If one of the keys in column A is pressed, the A register will not contain 017. Therefore, the JNZ to NXTKEY will be executed if one of the keys in the A column is pressed. If no key in this column is pressed, the 8080 executes the DCRD instruction, causing the content of the D register to be decremented from three to two. Since this value is not equal to 377, the 8080 jumps back to NXTGRP, so that the B column of the keyboard can be tested. Remember, the B register already contains the test pattern required to test this column of keys.

If a key in the A column is pressed (3, 7, 11, or 15), the 8080 calls the DELAY subroutine at

Contests

Robert Baker WB2GFE
15 Windsor Dr.
Atco NJ 08004

5 CONTINENT WORLD RTTY CHAMPIONSHIP 1979-1980
Sponsored by IATG-Radiocommunications

IATG-Radiocommunications and CD Publications, in continuation of their more than 10 years of activity promoting the most advanced radio amateur techniques, have decided to sponsor a new series of contests for teletypers of all continents.

The purpose of the contests is not only to increase interest among radio amateurs for the radioteletype, but also to promote interest in long-range contacts, that is, to stress intercontinental contacts rather than domestic and intracontinental contacts as in previous contests.

For this purpose, IATG and CD have organized the following three contests: Australia-Oceania and Asia RTTY Flash Contest—3/4 November 1979; North and South American RTTY Flash Contest—19/20 January 1980; Europe and Africa RTTY Giant Flash Contest—9/10 March 1980.

For each of the three contests, there will be a general winner plus a winner from each of the two continents involved.

Separate standings for each continent plus a general standing for each contest will be published in *CO Elettronica Magazine* and other magazines and points will be awarded as follows:

a) For contest winners: first place—50 points, second place—46 points, third place—43 points, fourth place—41 points, fifth place—40 points, etc., 44th place—1 point.

b) For continental winners (e.g., Australia-Oceania and Asia in the first contest): first place—25 points, second place—22 points, third place—20 points, fourth place—18 points, fifth place—17 points, etc., 21st place—1 point.

Standings are independent, that is, continental winners can also be general winners.

At the end of the three contests, continental and general standing points will be totaled and a *World Champion of the 5 Continents* will be declared according to the new final standing obtained.

Grand prizes, as usual, are reserved for the four first place winners. Consolation prizes along with medals and certificates will also be awarded.

AUSTRALIA-OCEANIA AND ASIA RTTY FLASH CONTEST
Contest periods:
0800 to 1800 GMT November 3
0800 to 1800 GMT November 4

This contest is sponsored by IATG-Radiocommunications to increase interest in intercontinental communications. Experience gained from this contest will be incorporated into the organization of future contests. All suggestions and constructive criticism are welcome. The DXCC list will be used except that the VE/VO, W/K, VK, PY, LU, JA, and UA0/9 call areas will be considered as separate countries. Use all amateur bands from 80 to 10 meters. Operating classes include single- or multi-operator, single transmitter, and SWLs.

EXCHANGE MESSAGE:

RST, number of the QSO, and continent.

SCORING:

Score 1 point per 80- or 40-meter QSO, 2 points per 20-meter QSO, 8 points per 15-meter QSO, and 12 points per 10-meter QSO. No points or multipliers for contacts with one's own country. Only 2x RTTY QSOs are valid. Each station may be contacted only once on any band; additional contacts may be made with the same station if a different band is used. Multipliers are given for countries and continents. A multiplier is given for each country worked on 20-10 meters. No multipliers for 80-40 meters. A separate multiplier may be claimed for the same country if a different band is used (max. of 3 times). Only countries which appear in at least 5 other logs will be valid as multipliers. One's own country is not valid as a multiplier. The continents are valid as multipliers; for contacts with Europe and/or Africa, the sender and the receiver will each be assigned 100 points as multiplier. 50 points will be assigned for each of the remaining continents contacted. An additional 100 points will be given for each contact with Australia-Oceania and/or Asia on 15 or 10 meters. Total points times total number of countries times total continent points plus total Australia-Oceania and Asia station points equals total score. Also, there are two promotional periods included in the contest: Saturday, November 3, between 1300 and 1400 GMT, and Sunday, November 4, between 1600 and 1700 GMT. Stations operating from NA, SA, EU, and AF contacting Australia-Oceania and/or Asia during these hours will *double* their points for these periods.

RTTYers entering logs in the contest who have not participated in previous contests will receive an additional bonus of 5% of their final score. Winners of previous RTTY Championships will receive 10% of the total final score; there is an 8% handicap of the total final score for the winner of one or more previous RTTY contests. This contest is also open to RTTY SWLs with the same scoring.

ENTRIES:

Use one log for each band. Logs must contain date/time in GMT, callsign, RST, QSO number, continent sent and received, country, and continent multipliers, points, and final score. In order to qualify, all logs must be received not later than December 15th. Send all logs to: Prof. Franco Fanti, Via A. Dallolio n 19, 40139 Bologna, Italy. Grand prizes are reserved for the four first place winners. Consolation prizes along with medals and certificates will also be awarded. Logs with compiling errors which exceed 10% of the final score will be excluded from the final standing and will receive/serve only as check logs. Logs will not be returned.

REMEMBER: this contest is valid towards the final standing of the 5 Continent World Championship!!!

IPA CONTEST
Contest Periods:
Saturday, November 10
0800 to 1000 GMT
1400 to 1700 GMT
1800 to 2000 GMT
Sunday, November 11
0800 to 1000 GMT
1400 to 1700 GMT
1800 to 2000 GMT

The International Police Association Radio Club—Section Francaise (IPARC) has organized a contest which will enable participants to work the Sherlock Holmes Award. The contest is open to all radio amateurs and SWLs. General call is "CQ IPA." Non-members may contact only members.

EXCHANGE:

Non-members send RS(T) and serial number. Members send IPA, RS(T), and serial number.

SCORING:

Every completed QSO counts 2 points on 80 and 40 meters, 4 points on 20, 15, or 10 meters. Staions may be worked once per band. Cross-mode and cross-band contacts are not valid. Multiplier is the nômber of IPA countries worked per band. Final score then is the total

REVIEW OF MAGGIORE COR IDENTIFIER

Everybody wants to build a repeater, it would seem. Many groups are stopped by the high cost of a "store-bought" machine and are unable to handle the task of designing the necessary logic for the identifier and COR circuits. If you fit this category, however, take heart. I was asked to do a review of the Maggiore COR Identifier, and since I have designed units for a competitor, it was felt that I would understand the unit and be able to appraise it in a knowledgeable manner. Before I get into the details of this unit, let me say this: If you are wanting to build a repeater, take a look at this unit.

When looking at the board, the first thing that you will notice is the diode matrix located at one end. The board given to me to test had 58 diodes installed. My first thought was, "Who wants to figure out and stuff all of those diodes?" My next thought was, "This unit comes wired and tested and diodes are a sure and safe way to program an ID." Upon closer examination, I found that the ID may be set for a short ID and the whole matrix does not have to be scanned, which is a nice feature.

Another nice thing about this unit is the provision for running a backup battery. If primary power fails and the repeater is running on battery, this unit produces a distinctive beep to signal the user that the repeater is on battery.

Interfacing this circuit to other circuitry should be a snap, because three inputs are provided for squelch information. One looks for a high-to-low logic change, one looks for low-to-high logic change, and finally another looks for a small voltage change in the noise amplifier of the receiver. It would seem to me that this covers just about every possible need that might arise in building your repeater.

The COR also provides a choice between an adjustable time-delay drop or an instant drop with the drop of the received carrier. This COR/ID circuit also has a built-in timer for the ID circuit. Assuming the repeater has been sitting unused and somebody keys it, the ID will cycle once and the timer will trigger. Until the timer times out, the repeater will not ID again. This is a good way of doing the ID time as the repeater will only ID while the repeater is in use. If the repeater has IDed and activity stops, the repeater will not ID at the end of the time cycle as the trigger that keys the ID after the timeout is the received carrier and that is not present since activity has stopped. The ID circuit produces an audio tone to go directly into the transmitter and has plenty of drive even to drive a small loudspeaker.

This circuit has another nice feature in that one of the option modes is a "beacon" mode. In this mode, the unit will produce a tone with regular IDs. This feature makes this unit good for the person who wants a beacon and might not even be interested in a repeater.

I did find a couple of things that I did not care for, but they are minor. One is the optional beep. I like the idea of the beep, but on this unit it occurs the instant the COR goes, which says that it is right on the end of the squelch tail. In talking to the people at Maggiore, I am told there is an option on a separate PC board that can be added to allow an adjustable delay before the beep, but I am sure this is not a problem to lose any sleep over.

Another thing I noticed was the timeout function. It is adjustable and can be disabled, of course, but when it times out, the repeater drops. It can be in the middle of an ID or anything else. The repeater would drop off the air. If the offending carrier clears, there is no way for the other users to know, except to give a kerchunck to see if the repeater responds.

One very nice feature of this circuit is the output key. It is a relay so that there should be no problems with interfacing to anything.

In way of summation, let me state that I rate this Maggiore COR Identifier quite high. The design is straightforward; the PC board is double-sided and of the hightest quality. The components are of high quality and are common parts. The circuit has a built-in connector so that it can be plugged in and out as necessary. And last but far from least, *the unit comes wired, tested, and programmed.* I say that for the money, it's hard to go wrong on this deal.

KANTRONICS' GENERAL COMBO

Kantronics' General Combo is a complete, carefully-organized program with the upgrading amateur in mind.

The *General-Class Amateur License Study Guide*, SAMS #21617, by WØXI, explains radio circuits in an easy-to-understand style. The primary purpose of the text is to assist the prospective General in obtaining the General class license.

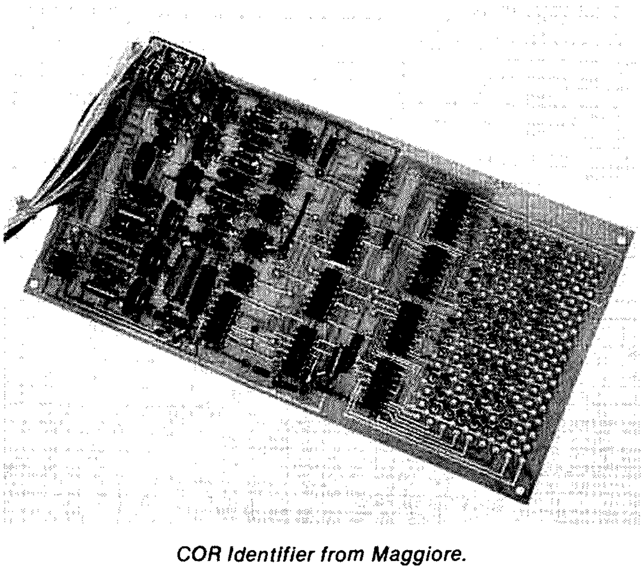
A second purpose of the text is to provide not only memorizable information for the exam, but also usable knowledge on electronics and practical radio circuits. The author's point of view is that an understanding of the material can then lead to a more detailed study of electronics later and to a greater enjoyment of our hobby, amateur radio.

Each chapter begins with introductory material and builds on this material to form more general concepts. The text explains the test, amateur regulations, radio-wave propagation, practical radio circuits, modulation characteristics, and transmission lines. Throughout each chapter, sample exam questions test your understanding of the material and prepare you for the FCC exam.

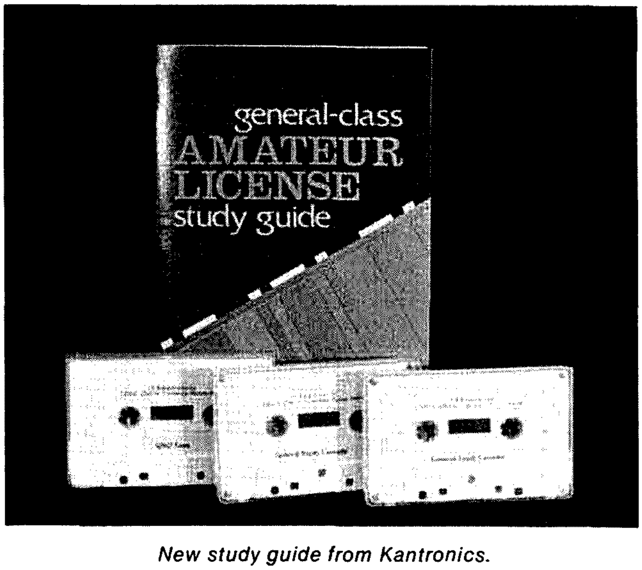
The General Cassette Tapes discuss rules, regulations, and radio theory in an interview format. The QSO Tape simulates exam-like "on-the-air" code transmissions. It progresses from 7½ to 15 wpm. Text key and practice exams are included. These test your proficiency in copying the content of the message and prepare you for the new FCC code test format. *Kantronics, Inc., 1202 E. 23rd Street, Lawrence KS 66044; (913)-842-7745.*

PERSONAL USE REPORT—THE BEARCAT BC-250 SCANNER

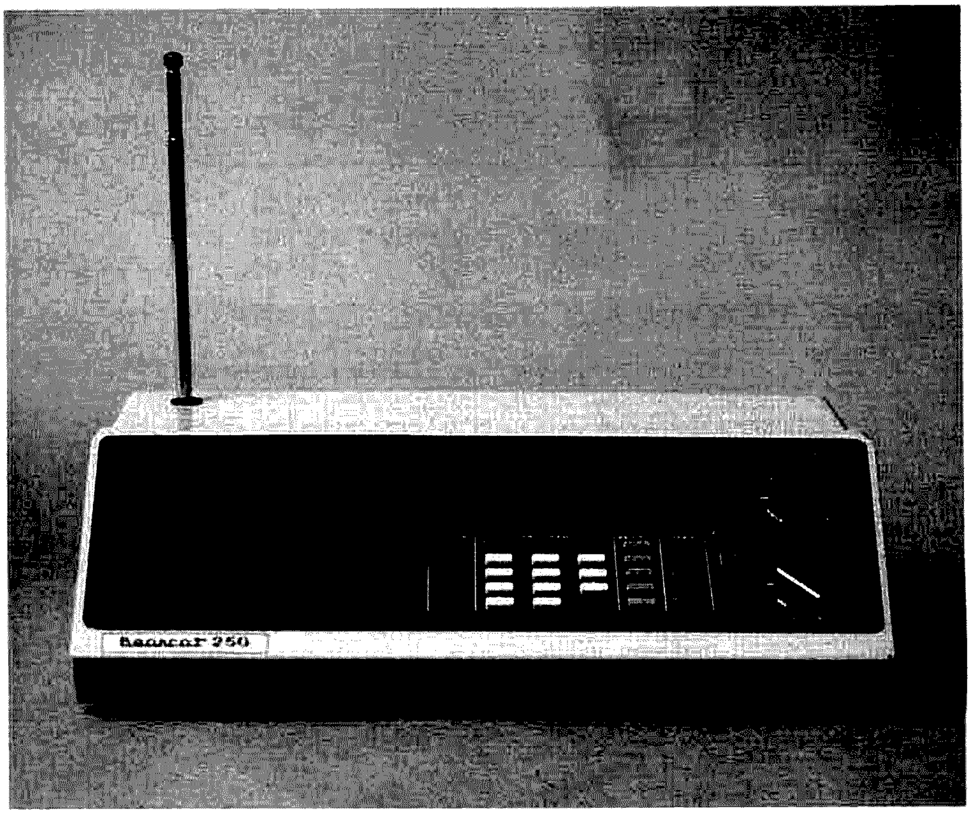
In the not-too-distant past, a great pastime was listening to



COR Identifier from Maggiore.



New study guide from Kantronics.



The Bearcat BC-250 scanner.

police calls on about 1700 kHz, just above the standard AM broadcast band. I can remember tuning the beautifully-cabineted Zenith that stood in our living room and feeling the excitement as dispatchers sent cars to various incidents.

In the quest for more channels and better communications, the police (and other emergency services) have moved to the VHF and UHF spectrums. Public Safety Radio, as it is called, still has police and firefighters, news reporters, radiotelephone calls, air rescue, G-men, weather forecasts, and just about any other safety service that you might imagine. The frequencies may be different, but the excitement is still there, and scanning monitor receivers have become the hottest item in consumer electronics since calculators.

Several generations of product development have yielded the Bearcat BC-250 scanner by Electra. When I saw the specs of this programmable scanner, I had to have one. After using it for a few months, I feel that it is a complete listening post in one package.

This microprocessor-controlled scanner needs no crystals for any of its 50 synthesized channels; frequencies are entered directly by a simple numerical keyboard. An 11-digit LED readout displays frequency, channel number, and function in large bold digits.

Any frequency in the five bands (32-50 MHz, 146-174 MHz, 420-450 MHz, 450-470 MHz, and 470-512 MHz) can be entered on any channel. Bearcat automatically retunes the front end for optimum sensitivity at any frequency, including the 2-meter and 450-MHz FM bands. The 50 channels are arranged in five groups or banks of 10 each. Each bank can be selected to scan or bypass. This allows you, for instance, to put the police on bank 1, fire on bank 2, and so on. My favorite local repeaters are on banks 3 and 4. If there are no QSOs that interest me, I just push a button and bypass those banks.

Momentary power outages or moving the radio to another room pose no problems for the BC-250. All frequencies are stored in a non-volatile memory that requires no battery. If power is lost, the scanner still retains all frequencies.

The Bearcat BC-250 has a unique search function to find those hidden or secret channels. Just enter an upper and a lower frequency limit and the BC-250 will check all channels between the limits. Active frequencies can then be read out on the display or entered into one of the 50 regular channels. It's great for finding those "secret" repeater inputs or special channels used by the local police.

A special 64-channel memory is set aside for use with the search function. In the search/store mode, the Bearcat BC-250 will search between the limits and automatically store the frequencies of up to 64 active channels. These can later be recalled on the display and/or entered into any of the 50 regular channels. The special memory also can be used to store frequencies to be bypassed during the regular search mode.

I hate to miss any action on the local "DX tip-off" frequency, so I program it on channel one. Priority listening is a selectable feature of the BC-250 that allows me to hear channel 1 whenever it becomes active, regardless of any other signals or functions. This is automatically done by momentarily sampling channel 1 and, if active, switching to that channel.

A two-second delay can be selected on any channel. This delays the start of scanning long enough to allow a reply to be heard on simplex channels. When things get boring on any channel, a lockout can be programmed. The BC-250 will then skip over that channel when scanning.

My favorite function available on the Bearcat BC-250 is the auxiliary control. This allows selective control of accessories connected to terminals on the rear of the scanner. I use the auxiliary control to record the paramedic channels on a battery-operated tape recorder while I'm not at home. When I am at home and not in the shack, a Sonalert triggered by channel 1 lets me know that the DX net is active.

The Bearcat BC-250 is, of course, 100% solid state. Most of the functions are controlled by seven custom-designed ICs. It has a sensitivity (12 dB SINAD) of .4 microvolts VHF and .6 microvolts UHF. Dual power supplies allow operation on 117 V ac or 12 V dc. There are external antenna and speaker jacks on the rear, and the scanner comes with power cords and a mobile mounting bracket. Useful even when not scanning, the BC-250 also functions as a highly-accurate digital clock, displaying time to the second. The darn thing's so exciting, my CW is getting a little rusty.

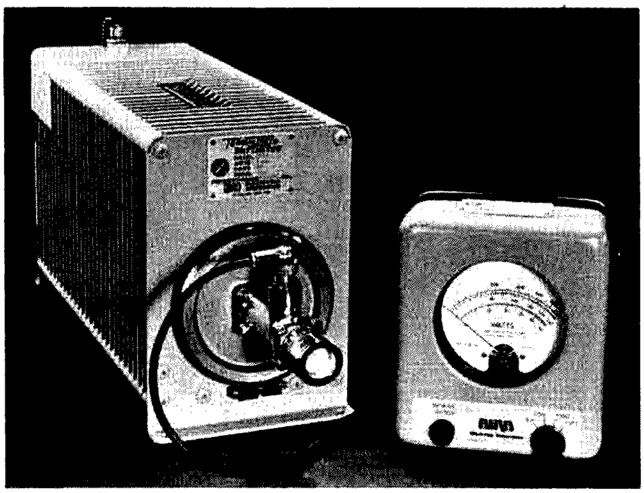
MORSE CODE PROGRAM AVAILABLE FOR THE TRS-80

Cost Effective Computer Services announces the AMCT-80, a program for the TRS-80 to teach and build proficiency in receiving Morse code. AMCT-80 (Automatic Morse Code Teacher) is the only Morse code program available that will automatically speed up or slow down depending on the student's proficiency in receiving code. Among the many options is the ability to receive in single or group character mode. Written in machine language, AMCT-80 is available for Level 1 and Level 2 TRS-80. *Cost Effective Computer Services, 728 S. 10th St., Suite #2, Grand Junction CO 81501.* Reader service number C124.

NEW MULTI-PURPOSE TERMINATION WATTMETER

A new-concept series of 10/50/250-Watt to 100/500/2500-Watt Rf Absorption Wattmeters/Line Terminations with convenience features suggested by communications users has been designed by Bird Electronics Corporation. The eight new models are direct-reading termination instruments for servicing 50-Ohm communications systems and for maintaining them at peak operation.

The new TERMALINE® wattmeters feature three power ranges selected by switch. This flexibility, without the need to transfer the crystal diode, frees one hand for equipment fine-tuning or troubleshooting. The new series 6730 wattmeters can be checked and calibrated *in the field* to a known standard. Frequency coverage has been



TERMALINE® Wattmeter, model 6736, 50/250/1000 Watts.

extended and the use of Schottky diodes increases long-term reliability.

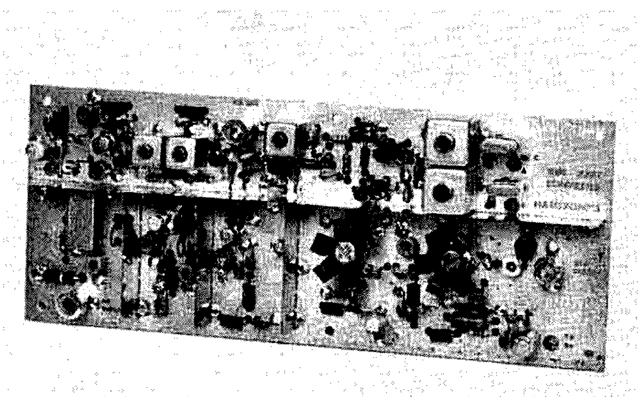
Wattmeter and load sections are joined with the patented quick-change QC feature, which allows easy separation. The load resistor can then serve as an independent termination.

The eight models have full-scale power values of 250, 500, 1000, 1200, and 2500 Watts and frequency coverage of 25 to 1000 MHz or 1.5 to 35 MHz. Vswr of the terminating loads is less than 1.15 from dc to 1000 MHz. The new series joins established TERMALINE Wattmeters with scales from 2 Watts to 150 Watts. Available from *Bird Electronics Corporation, 30303 Aurora Road, Cleveland (Solon) OH 44139; (216)-248-1200.* Reader service number B10.

NEW UHF TRANSMITTING CONVERTER FROM HAMTRONICS

Hamtronics, Inc., has done it again! In the tradition of other fine products, they have a new UHF transmitting converter, and just in time to gear up for the new OSCAR Phase III. Designed to convert 28-30 MHz to 435-437 MHz or 432-434 MHz, the new model SV4 requires 1 mW to 1/2 W of drive to give 1 W PEP output on SSB or up to 1-1/2 W on CW or FM. If you have one of the older 10m exciters which doesn't have a low power transverter output, don't worry, because instructions with the XV4 tell you how to make a simple attenuator. The best thing about the XV4 is the price—it costs much less than other types of equipment which have been available until now. Even adding an LPA 4-10 10-Watt linear power amplifier, a C432 UHF receiving converter, or a C144 VHF receiving converter to the system, you still save a bundle of money! The XV4 has an oscillator output to be used with a receiving converter if you like to transceive. It also has two oscillators, so it is easy to change frequency ranges without returning. For those who have a 2-meter multimode rig, an XV28 adapter is available to allow the XV4 transmitting converter to operate with a 2-meter input signal.

For more information, call or write for free catalog on these and other VHF and UHF kits, including preamps, converters, FM transmitters, and receivers. *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468; (716)-392-9430.* Reader service number H16.



The XV4 transmitting converter from Hamtronics.

A REVIEW OF THE ATLAS TX-110

Cute little box! That was my first impresssion as I sat down before the dark grey and black cabinet. I had come into Georgetown Communications only to browse, with not a thought of spending a dime, even less of falling in love. A very impressive price, indeed, but was it a receiver or a transmitter?

"It's both," a voice behind me said. Carl **N4AA**, the owner, handed me a key and told me to take it for a spin.

You see, the Atlas RX-110S is Atlas's hot new allband receiver, and with the addition of the TX-110 transmitting module, it's an all-solid-state SSB and CW transceiving package.

Well, OK, let's see what it'll do on the oval track. Ah, a CQ . . . WB2XXX DE N4KJ . . . Hey, instant reply, and a 589 to boot! Semi-automatic break-in keying, 800-Hz CW filter, and built-in sidetone—not bad at all!

When I finished with the QSO, I asked Carl for a mike and quickly switched to 20 SSB. A W7 answered my CQ, but a bit high in frequency; no problem, the RX-110S is equipped with receiver incremental tuning. I'm impressed . . . I'll drive it home.

In the shack, I gave the little box a real operator's shakedown. The transmitter runs 20 Watts input or, with the high power module added, a full 250 Watts is possible. The output is broadbanded, which requires no tuning, and it's fed to the antenna via an SO-239 connector (not a cheap phono plug). In addition to the relative output meter on the front panel, there's provision to monitor current to the solid-state final amplifier. There's plenty of mike gain, and audio quality is excellent. The CW note is likewise "clickless" and chirp-free.

As I mentioned before, this is a transmitting module; certain stages of the RX-110S are required to make a complete transmitter. All connections for this are supplied through a 12-pin connector plug.

Jarring the receiver around, I found the mechanical stability excellent. Drift also is well within the 500-Hz figure as quoted in the manufacturer's specifications. The tuning dial reads to 5 kHz with 1-kHz marks on the tuning knob skirt. The handy RIT control I mentioned tunes up and down 5 kHz from the transmit frequency. When I switched the 800-Hz filter on a CW signal, a clean note with little ringing was realized. The receiver uses no rf stage, but behold the .25 microvolts for a 10-dB S + N/N sensitivity figure. Selectivity on SSB is 2.7 kHz at 6 dB down with a 2.2 shape factor, provided by a 6-pole crystal ladder filter. Image rejection is better than 60 dB. There's also plenty of audio—2 Watts into the internal 3-inch speaker. Dynamic range is rated at a terrific 80 dB above a noise floor of 130 dB. On-the-air tuning is smooth, and with no backlash you get the feeling of operating a much more expensive rig. Key down, the low-power transmitter draws about 2 Amps, or 16 Amps with the high-power module addition. I used my home-brew supply, but Atlas makes a nice matching supply along with many other accessories. A bracket and hardware are supplied to join the receiver to the transmitting module, making a great compact station.

I travel quite a bit, so the Atlas will be a nice traveling companion. Hours of operating pleasure are ahead from my new-found friend. So, congratulations, Atlas! A cute little rig!

Atlas Radio, Inc., 417 Via Del Monte, Oceanside CA 92054; (714)-433-1983. Reader service number A16.

M80 USER REPORT

The Macrotronics M80 ham interface for the Radio Shack TRS-80 computer includes an interface board and software for RTTY and CW operation. The hardware employs one board which provides access to the computer through the expansion port (an expansion interface is *not* required). On and off pulses generated by the computer can be coupled by a relay with normally-open or normally-closed contacts (or an accessory optoisolator for keying RTTY loops), a PNP transistor, or an NPN transistor. These options permit keying of virtually any transmitter for CW or FSK or the RS-232 input of a TTY AFSK system. For receiving CW or TTY, the board transfers pulses to the expansion port of the computer. This can be accomplished by providing the board with receiver audio which is detected by a phase locked loop or by connecting the RS-232 leads of a demodulator to the board. With the optional optoisolator, the board can be keyed directly by the TTY loop supply.

The software includes machine-language routines for CW and TTY encoding and decoding and a BASIC program for running the system. The instruction manual supplied with

New Rig for 10 FM

—a review of the Comtronix FM80

Dave Ingram K4TWJ
Eastwood Village 1201 South
Rte. 11, Box 499
Birmingham AL 35210

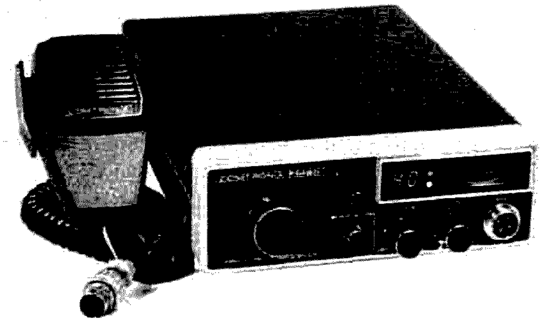
An exciting new frontier in amateur communications is presently being pioneered on the high end of 10 meters, and this field promises to gain widespread acceptance in the near future. Channelized FM operations similar to those presently enjoyed on 2-meter FM are producing worldwide communications for amateurs using small, low-power transceivers. DX propagation on 10 meters is on the upswing, and this condition shows no sign of diminishing in the near future. Meanwhile, 10 meter FMers are having the time of their lives working the world on this fascinating high-frequency band.

Although 10 FM supports a substantial amount of activity each weekday, this band becomes an absolute blowout of fun and pleasure every weekend. This super-excitement usually begins around midday Fridays and continues full blast until the band drops out Sunday evenings. During these periods, stations in all areas of the world frequent the internationally popular frequencies of 29,600 kHz or 29,620 kHz as activity booms and QSOs flourish. On numerous occasions, the DX activity on 10 FM resembles a gigantic 2-meter band opening with station signals stacking 5 or 6 layers deep.

Until recent times, most of the equipment used on 10-meter FM consisted of single-frequency business units which were usually retuned for operation on the International Direct Frequency of 29,600 kHz. As activity has increased, this "channel" has become quite busy, and secondary "channels" of 29,620, 29,640, and 29,680 kHz are also becoming popular. In order to assure the acceptance and future development of 10 FM, pioneering amateurs are now working toward the common goal of distributing on-the-air activities throughout the high end of 10 meters. Ultimately, this will divert mass pileups from 29,600 kHz during periods of intense activity. A substantial number of FM repeaters operate on the high end of 10 meters, and their performance is fantastic. Most of these repeaters employ 100 kHz input/output spacing, so that an input signal on 29,540 kHz would output on 29,640 kHz.

Several areas of the United States enjoy the pleasures of 10-meter-linking with their 2-meter repeaters to create "super machines". The Las Vegas machine, for example, permits HT-equipped amateurs to communicate with others thousands of miles away via a 2-to-10-meter link. An inestimable number of individually owned remote base units is active on 10 FM, and their operators truly have the world at their fingertips.

My first 10 FM rig was a single-frequency unit which ran 5 Watts on 29,600 kHz. I recently switched to the multi-frequency Comtronix FM-80, however, and the results have been a totally new ball game. Obviously, the Comtronix FM transceiver will prove to be a super-innovation for 10 FM.



The Comtronix FM80 with matching microphone. This compact unit places the wide world of 10 FM directly at one's fingertips.

The Comtronix

When UPS delivered the Comtronix package, the carrier dropped it approximately 2 feet to the floor (what else is new)! I quickly unpacked the unit and carried it to my car to check damage. When I connected the FM80 and switched on power, stations in Montana and Washington state came booming through. The FM80 is definitely a stout-hearted rig! A quick check with my trusty W4 wattmeter indicated 10-Watts output, which was exactly as Comtronix advertised. While mobiling home that evening, I worked California, Arizona, and Alabama. All stations agreed the FM80's audio sounded very good and its signal strength was quite ample (low power is very popular on 10 FM).

During the first weekend I used the Comtronix, some serious medical problems limited my on-the-air operations to a total of 2 hours—and much of this time was interrupted for handling chores. I did, however, manage approximately 12 contacts with 9 countries in four of the world's 7 continents. The FM80 was used barefoot during these operations, and the antennas used

were either a Hy-Gain TH3 triband beam or Newtronics 4-BTV vertical. One DX contact was also made from my car while using a Hustler mobile whip. Need I say more?

The Comtronix FM80 is a compact unit which operates directly from an auto's 12-volt battery or an external 12-volt power supply. Current requirements are approximately 350 mA during receive and 2.2 Amps when the unit is transmitting at high power. Frequency coverage is 28,910 kHz to 29,700 kHz in eighty 10-kHz channelized steps. 40 channels are covered with a front-panel switch "in" (CHA), and the additional 40 channels are covered when this switch is "out" (CHB). FM operations are not legally permitted on the first 9 positions of CHA (28,910 through 29,000 kHz), so the operator must remember merely to listen in this range. 10 FM activity is far removed from this range on either CHA or CHB, however, so no problems should be encountered. Transmission on frequency positions 6 through 25 of CHB (29,360 through 29,550 kHz) should also be avoided, as this range is used by OSCAR amateur satellites. Considering that the FM80 is capable of covering part of the *73* 10-meter band plan (provided the unit is modified for AM operation), plus receiving OSCAR satellite signals (provided a simple product detector and bfo are added), I suspect modification-oriented amateurs will make a mad dive for this rig. I'm already thinking of ways to use my FM80 on 29,150-kHz medium-scan TV, plus mating it with my similar-sized 2-meter rig for OSCAR mobile work. I have also used a 2-carrier operated relay interface between the FM80 and my TR-7600 for occasional remote base functions. A scanning adapter, priority channel, and memory function also are being considered, and a portable pack containing a motorcycle battery and short whip antenna are future considerations.

In addition to being an outstanding performer, the Comtronix FM80 is a beautifully engineered and packaged unit. A dark plastic sunscreen on the front panel's upper right corner covers the channel LED readout, illuminated S/output meter, and two function-monitoring LEDs. One LED is bipolar: green during receive and red during transmit. The other LED changes intensity according to audio input from the mike. This feature is particularly beneficial since FM signal amplitudes do not vary during modulation.

Since I also operate a Yaesu FT-901DM on 10 FM, I've received numerous requests for a personal comparison of the Yaesu and the Comtronix. Here is my opinion: The Comtronix is broadband—pretuned and all solid state, whereas the Yaesu uses 6146s and requires loading. I definitely prefer tube finals for low-band DXing and SSTV operations, but the FM80's "instant on" can't be beat for FM activity. Published specs rate the 901DM's receiver more sensitive than the FM80's, but I've found performance of both units identical. Yaesu suggests running the 901DM at 20-Watts output on 10 FM, and I think this is an excellent idea. Transmitted signal strength comparisons on the 901DM and the FM80 (10-Watt mode) are usually identical. Frequency/channel changes are easier with the FM80, but the 901DM's memory is great for repeater operations. Comtronix now has a split-frequency modification for repeater operation and Cushcraft just introduced a 10m FM Ringo.

Table 1. 10 FM band plan.

In conclusion, I feel 10 FM is a fantastic frontier and the Comtronix FM80 is a superb little rig. The unit is easy to carry, it's great for mobile operations, and it doesn't represent a life's savings when gleaming under the dash of an automobile. It will never replace my low-band all-mode transceiver (FT-901DM), but it isn't intended for that purpose. The FM80's receiver is double-conversion with a first i-f of 10.7 MHz and a second i-f of 455 kHz. Its sensitivity is excellent (.5 microvolt for 20 dB quieting; squelch threshold also at .5 microvolt), and its selectivity is quite adequate (10 kHz at 15 dB and 20 kHz at 40 dB). Ultimate image rejection is better than −60 dB, and an rf output filter is included to eliminate spurious radiations.

If you would like to renew your interest in amateur radio and enjoy pioneering a great new frontier, grab one of these units and mobile to the nearest mountaintop. It's a grand experience. ■

The Black Art of Antenna Design

—shedding some light on the workings of vertical whips

The purpose of this article is to correct some widespread misconceptions about antennas. These misconceptions, as will be explained later, are not confined to certain users of an-

Fig. 1. (a) Zepp antenna with feedline. (b) Zepp with feedline removed. (c) The one-terminal impedance.

tennas, but evidently extend to some of the manufacturers as well. Unfortunately, there is a widely-held belief that antenna design is a "black art." While I do not wish to undermine the livelihoods of those well-qualified antenna engineers who thrive on perpetuating the notion that the operation of an antenna is incomprehensible to the layman, I do feel that some of the secrets should be revealed in the interest of the betterment of ham radio!

The Problem

The problem to be treated in this article is related to the way in which antennas are connected to transmission lines. We will exclude from the discussion microwave antennas such as horns or slots which are driven by waveguides. Practically all other antennas possess two terminals, the points at which one can say that the transmission line to the transmitter or receiver is connected, and the antenna begins.

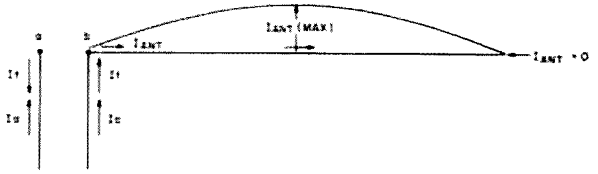

Fig. 2. Current distribution on the Zepp antenna.

The problem arises from what I shall call the "one-terminal impedance" misconception. As a starting point, let's take a look at an old and time-honored antenna, popular in the early days of ham radio, known as the "Zepp," and shown in Fig. 1(a). The Zepp consists of a half-wave wire, usually mounted horizontally, driven at one end by a two-wire transmission line. The feedline is normally one quarter-wavelength long, and is usually coupled inductively to a tuned circuit at the driving end. The antenna is said to be "voltage fed" because the extremity of a wire antenna is a point of high voltage and low current.

You must surely agree that terminals A and B in Fig. 1(a) are the input terminals of the antenna because this is where the two-wire transmission line is connected. If we concentrate on the antenna alone, we have the situation portrayed in Fig. 1(b), where point B is one end of the half-wave antenna, while point A is a disembodied point hanging in the air. What, then, is the impedance terminating the transmission line? It is evidently infinite, because an impedance is the ratio of an ac voltage to an ac current. An ac voltage, V_{ab}, applied across the two terminals of an antenna should certainly excite the antenna. If such a voltage generator is applied across terminals A and B, as shown in Fig. 1(c), no current can flow, because the same current which goes out of one terminal of the generator must come into the other, and in this case, terminal A is not connected to anything. But there *must* be a finite current entering the

antenna at the feed point, or there could be no power radiated by the antenna! Here lies the misconception which I have called "one-terminal impedance."

This dilemma was known to at least some of the early users of Zepp antennas, as can be verified by studying technical literature on the subject written 40 years ago. The truth of the matter is that the transmission line *must* also be a part of the antenna.

Since the horizontal part of the antenna is a half wave in length, there will be a standing wave of current along the wire with a magnitude of zero at the far extremity, maximum in the center, and small, *but finite*, at the driven end (see Fig. 2). The magnitude of this input current depends on the length-to-diameter ratio of the wire, and will be about 25 percent of the maximum current at the center for a length-to-diameter ratio of 100. The current on the transmission line wires will be composed of two components, the first of which is the ordinary transmission line component with equal and opposite currents on the two legs. This component is designated as I_t in Fig. 2. The second component is the antenna current, with equal amplitudes and equal directions on both legs, shown as I_a in Fig. 2. At point A, the total current must be zero. Thus, I_t and I_a must be equal in amplitude but 180° out of phase to add up to zero at A, and equal in amplitude but in phase to add up to the current entering the antenna at point B, labeled I_{ant}.

The transmission line currents are produced by the transmitter, usually through inductive coupling at the input end of the two-wire line. The antenna current is in the form of a standing wave on the antenna wire, but its distribution along the feedline is in some doubt. The electromagnetic field due to the transmission line currents alone is localized in the near neighborhood of the feedline, but the field due to the antenna currents is not so confined—in fact, it produces substantial radiation from the feedline. There will be coupling by this field to nearby objects such as to the building in which the transmitter is located, and to any electrical conductors nearby. The input end of the feedline will have inevitable capacitive coupling to the transmitter chassis, and the entire transmitter will be hot with rf, along with the house wiring. At higher power levels, the operator may receive rf burns when his lip brushes up against a metallic microphone! Frankly, the old Zepp antenna is a mess!

All of this is easily corrected by moving the feedline to the center of the half-wave dipole, which is a point of symmetry. The radiating antenna currents are now confined entirely to the antenna and no antenna currents are superimposed on the transmission line currents. Note, however, that this situation prevails only as long as a balanced transmission line is used to feed the antenna. If coaxial cable is used, then an appropriate "balance-to-unbalance" transformer, or balun, must be employed between the coaxial line and the antenna to inhibit currents from flowing on the outside of the coaxial cable.

While the old Zepp antenna is rarely used today, there are many other antennas in common use which must be driven from one extremity. These are the class of vertical whips in which the feedpoint is elevated above earth ground, highly popular for base station use in the VHF and UHF bands in amateur, commercial, and marine service. This class of antennas is used in an effort to obtain vertically-polarized radiation which is omnidirectional in azimuth. Unfortunately, the one-terminal impedance misconception, which should have been laid to rest 40 years ago, has reappeared with a vengeance!

Antennas are commercially available from a number of different manufacturers which consist of a vertical whip extending up from an impedance-matching network at the base, which is fed through a coaxial cable connector. The most popular lengths for the whip are 1/4, 1/2, and 5/8 wavelength. If this type of antenna is used on the outside metal surface of an automobile, there is no problem. One has a kind of highly-unbalanced dipole, one leg of which is the whip, the other being the outside metal surface of the car. The outer conductor of the coaxial cable is electrically connected (either conductively or capacitively) to the car body, while the center conductor couples to the whip. The

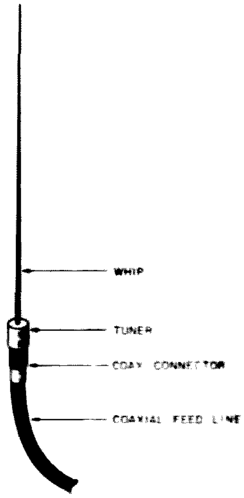

Fig. 3. Typical whip with base tuner connected to a coaxial line.

same magnitude of current which enters the base of the whip must also spill out over the car body. If the antenna is mounted *at a point* of symmetry, ideally at the center of the rooftop, current will flow radially out from the base of the whip, as in the case of a vertical broadcast antenna system. The car top is an elevated "ground plane" of finite size. The radiation pattern will show only minor variations in azimuth, but the maximum radiation inten-

sity will typically occur at some vertical angle above the horizon. This effect is usually tolerated as the price to pay for the simplicity and economy of the simple vertical whip extending from the car body. (Incidentally, severe asymmetry in the mounting location of a VHF vehicular whip can result in a highly-irregular azimuthal radiation pattern.)

The great one-terminal impedance misconception rears its head again when an automotive-type whip antenna is connected to the end of a coaxial transmission line, with the automobile deleted. This situation is not uncommon. Many an amateur radio operator has bought an automobile whip for home use, stuck it out of the window, and connected it to his 2-meter base station through a length of coaxial cable. If he could only see where the rf was going, he would be shocked! (At the end of this article I will reveal the design of a handy device which actually *can* make the rf visible!)

For ham use, degraded performance is not usually a critical matter. The user may be unaware of the degradation because he is still able to work other stations. The user may be quite happy. Unfortunately, users rarely receive any technical guidance from either the manufacturer of the antenna or the dealer, both of whom are principally concerned with sales. A much more serious problem arises when the automotive-type whip antenna is used in other than ham radio service, for example, in the marine band of 156-162 MHz. If you happen to live in a coastal area where large marinas are located, look at the sailboats and see how many vertical whip antennas of the thin wire, automotive type are mounted on the mastheads. As will be explained below, this type of antenna system can produce severe degradation of the radiation pattern, caused by unwanted currents excited on the outside of the coax line as well as on the stays, shrouds, and the mast itself—all functioning as longwire antennas. The degradation in communications performance could result in tragedy because of the inability of the boater to summon help in an emergency situation. I cannot believe that the manufacturers and dealers of these antennas are aware of the problem; it is much more likely to be a matter of ignorance. It happens that there *do* exist well-designed vertically-polarized marine VHF antennas on the market, in which the radiating element is superbly decoupled from the coax line and mounting structure. It is unfortunate that in this consumer-oriented market, when the sailboater asks for a lightweight VHF antenna, the dealer happily sends him off to his (possible) doom with degraded communications capabilities!

Returning to the one-terminal impedance misconception, Fig. 3 portrays a typical coaxially-driven whip antenna with tuner in the base, connected to a coaxial cable. The antenna might be either a half-wave or 5/8-wavelength whip.

A popular network for impedance-matching the whip to the coax line is shown in Fig. 4(a). This is an L-network in a configuration useful for a load impedance whose resistive part is greater than 50 Ohms, as in the case of both the 1/2- and 5/8-wavelength whips. Another possible tuning network, using a tapped inductor, is shown in Fig. 4(b). Capacitor C in Fig. 4(b) is sometimes deleted, and the length of the whip is made variable in order to gain another tuning parameter.

We now come to another point about which I suspect there are misconceptions among many amateur radio operators. This concerns the respective roles of the *inside* and the *outside* of the coaxial line. The transmitter normally resides within a rather well-shielded box. The signal generated by the transmitter is conveyed *within* the coax line to the feedpoint of the antenna before it (the signal) emerges and first "sees the light of day." I like to call the shielded interior of the transmitter and the inside of the coax cable out to the antenna terminals the "inside world." The "outside world" consists of the whip antenna *and the outside surface of the outer conductor of the coax line!* This is the point missed by many users of antennas. They perceive of the coax line purely as a transmission line connecting their transceiver to the antenna, and fail to understand that it can also be a part of the antenna. Please understand that this is not a new or revolutionary concept, but has been well understood by antenna engineers during at least the last 35 to 40 years.

Looking down into the coax line between points A and C—see Fig. 4(a)—we can replace the "inside world" by a voltage source, V_g, in series with an internal impedance, Z_g. This is an application of Thevenin's theorem—well known to all electrical engineers. The voltage source drives the antenna impedance, Z_a, through the LC network, as shown in Fig.

5(a). The circuit can be simplified by including the tuner as a part of the effective source impedance, looking back toward the source at terminals B and C, as shown in Fig. 5(b). The effect of the tuner is to modify the source voltage to a new value, $V_{g'}$, and the source impedance to $Z_{g'}$. The tuner can properly be considered to be a part of the "inside world." You could just as easily mount the L and C elements just inside the coax line as shown in Fig. 5(c).

Aha! We now note that the load impedance terminating the coax line is connected across terminals B and C. If we disconnect the coax line with its tuner from the antenna, we are left with only one terminal (B), the other terminal having been carried away with the coax line! The one-terminal impedance problem has struck again.

We are led to the correct conclusion that the coax line must provide the other "half" of the antenna. Antenna currents *must* be carried on the outside of the coax line. Unlike the open-wire feedline of the Zepp antenna, where transmission-line and antenna currents were superimposed, the coax line forces the antenna currents to be entirely on the outside of the outer conductor. This results from the fact that a coaxial line forces currents *within* the line to be equal and opposite on the center conductor and inside wall of the outer conductor, respectively. The antenna current is forced to flow on the outside surface of the outer conductor.

The antenna is really a horrendously unbalanced dipole, as shown in Fig. 6, the two sides being (1) the whip itself, and (2) the outside of the coax line all the way to the transmitter, the outer box housing the transmitter, and, very possibly, many other conductors associated with the system, such as the microphone cable, leads to a power supply, house wiring, etc.

The magnitude of the antenna current at all points along the outside of the coax line is not easily predictable. One can be sure that at the feed point the instantaneous current, I_a, entering the whip must be exactly equal to the antenna current at the extremity of the outer conductor of the coax line (see Fig. 6). Below the feed point, the current on the outside of the coax will probably be in the form of standing waves produced by reflection processes at the bottom end of the coax-transmitter system. At the antenna terminals, the standing-wave amplitude on the outside of the coax could produce a current maximum (resonance), current minimum (anti-resonance), or anywhere in between. If there are many wavelengths of coax between the transmitter and the antenna terminals, there will be only a small percentage difference in frequency between resonance and antiresonance. The degradation of the radiation pattern is highest for antiresonance conditions on the cable, at which time the resulting radiation pattern in the vertical plane will be broken up into a mass of lobes. Additional degradation will result from power loss where the coax line is in close proximity to lossy materials, such as the wall of a house, the ground, etc. Also, horizontal runs of the coax between the antenna and the transmitter will radiate a component which is cross-polarized with respect to the radiation from the whip.

If you are skeptical, make up an rf sniffer like the one described at the end of the article, and convince yourself! Connect a 2-meter band, automotive-type whip at the end of a length of coaxial cable of arbitrary length—3 feet, 6 feet, 10 feet—whatever is available. Connect the other end to your 2-meter rig. Ten Watts of output power is a satisfactory level for good rf sniffing, but higher power produces more spectacular results.

First, while transmitting (on some unused frequency!), bring the coupling loop of the sniffer up toward the whip. For maximum coupling, the plane of the loop should lie in the plane containing the whip. Tune the loop with an insulated tuning tool to obtain maximum brightness in the indicator lamp. You can search along the whip and see the standing wave of current, since the loop is magnetically coupled and a point of maximum brightness means of a point of maximum current. Now search with the sniffer along the coax line below the antenna. Provided that your rig really is putting out the better part of 10 Watts, or more, the sniffer will light up merrily along the coax all of the way back to the rig!

I have performed this demonstration (with good effect) before a number of different ham groups. At one meeting, I also demonstrated a 2-meter model of a Zepp antenna, and showed how the feedline was strongly radiating. After the meeting was over, one of the old-timers present said to me, "That demonstration of the Zepp was like killing an old friend!" I prefer to think that I was helping kill an old bandit who had been

robbing the hams of rf power for years!

Some representative measured radiation patterns of whips showing the effects of radiation from the coax line are shown in Fig. 7. The azimuthal pattern of a vertical whip is necessarily omnidirectional. The radiation pattern in the vertical plane is most easily measured by supporting the whip horizontally above a turntable, and rotating it in the horizontal plane at a fixed height above the earth. A signal generator on the turntable drives the antenna, and the radiated signal is picked up at some distance away on a horizontally-polarized antenna, amplified, detected, and plotted on an automatic chart recorder, the paper drive of which is synchronized with the rotation of the turntable. The vertical polar diagrams of Fig. 7 were obtained in this way, using a commercial antenna pattern recorder and facilities of the University of Washington. The original recordings were made in terms of a decibel plot on an X-Y recorder, and were carefully replotted in a polar diagram to make the result more generally understandable.

Fig. 7 shows the relative radiated power versus vertical angle for 3 different end-fed whip antennas, all patterns normalized to a maximum value of unity. Each of these antennas was mounted horizontally, with the coaxial feedline extending out in line with the whip for a distance of 8½ feet, and then coming vertically down to near ground level, and then back to the turntable.

Pattern 1 is that of a commercial half-wave whip with tuner in the base. Note how the pattern is of "butterfly" shape, with lobes above and below the horizon. This is a typical result of the radiation from the coax combining in and out of phase with the component from the whip. The pattern would be much worse if even a greater length of coax extended down from the base of the whip, the main effect being to break up the vertical pattern into a mass of lobes, with no assurance that there would be a maximum of radiation toward the horizon.

Pattern 2 is that of a 5/8-wavelength whip with base tuner, and it exhibits considerably more severe degradation than the half-wave whip. This arises from the larger base current of a 5/8 whip than in a half-wave whip, resulting in a correspondingly larger "spill-over" current on the outside of the coax.

Pattern 3 is that of a half-wave whip with a quarter-wavelength decoupling sleeve, to be described in the next section. Only slight pattern distortion is evident, this being due to the small current necessarily excited on the decoupling sleeve.

Finally, pattern 4 is that of a center-driven balanced dipole which is used as a test antenna to calibrate the antenna range.

The Cure

The conclusion to be drawn from the above discussions and test results is this: Use your mobile whip antenna where it belongs (on your car) and be skeptical of any commercially-available antennas which are claimed to be designed for base station use but which consist of an end-driven vertical radiator with no decoupling system evident.

How then can you radiate a clean, omnidirectional, vertically-polarized signal from an end-driven whip antenna, and know that it is performing correctly? Again, we turn to the old pros, the antenna engineers who have known how to design such antennas for the last 40 years, and have been furnishing them to the commercial trade, to the military services, the government agencies, the telephone company, etc. These are the sophisticated users, who are not fooled by advertising claims, and who insist on proof of performance, including measured radiation patterns under specified conditions and measured gain figures, before they buy.

The solution to the problem of end-driving the whip is to employ a suitable "decoupling system" to inhibit the antenna currents from flowing down the outside of the coax. For the VHF bands, one of the most widely used and (when properly designed) highly effective systems employs a 1/4-wavelength section of tubing, extending down from the base of the whip over the outside of the coax line, as shown in Fig. 8. This system is very effective for half-wave whips, very poor for 5/8 whips, and only fair for 1/4-wave whips. (This last design has been called a "sleeve dipole" for many years.)

Note in Fig. 8, which shows a half-wave whip, that the outer conductor of the coax line at the base of the whip is folded down and over the coax in the form of a quarter-wave sleeve, which is open at the bottom. For good decoupling, the diameter of the sleeve must be considerably greater than the outer diameter of the coax line, at least in the order of 5 or 10 to one. Looking up into the open end of the sleeve, one sees a coaxial line with the sleeve as the outer conductor, and the outer surface of the feed coax as the inner conductor. This coaxial line is open at the bottom end, but terminated at its top end in a short circuit. At quarter-wave resonance, there is a high impedance between the lower lip of the sleeve and the inner coax line. This impedance is in the path of the "spill-over" current, and forces a current minimum to exist at this point. There is a portion of a standing wave of current on the outside of the sleeve, with maximum amplitude at the top of the sleeve. This max-

imum amplitude is small, since it must be equal to the base current entering the whip. The other end of the standing wave is at the open end of the sleeve, where the current amplitude is practically zero. The outside of the coax line below the sleeve is now very effectively decoupled from the antenna. The current distribution along the entire structure is shown in Fig. 9. The small section of a standing wave on the decoupling sleeve is in phase with the current on the whip, but has little effect on the radiation pattern, as was shown in Fig. 7. A commercially-available version of this antenna, designed for the 156-162-MHz marine VHF band, is shown in Fig. 10. This antenna is particularly attractive for masthead mounting on sailboats, because the decoupling sleeve prevents the stays, shrouds, mast, etc., from becoming inadvertent parts of the antenna.

A 5/8-wavelength whip cannot be decoupled effectively with a quarter-wave sleeve, as can be seen by the current distribution shown in Fig. 11. The standing wave of current along the whip has a phase reversal one half wavelength down from the top. The feedpoint current amplitude is 70 percent of the maximum current, and the current at the top of the decoupling sleeve must have the same amplitude and phase as the current at the base of the whip. The result is that even though the coax line below the sleeve may be fairly well decoupled, the radiation pattern of the antenna will be poor. Radiation toward the horizon from the upper and lower halves of the system tends to cancel, with maximum radiation occurring in lobes at high and low angles.

A more intelligent way to drive a 5/8-wavelength whip is to place the quarter-wave decoupling sleeve down below the feedpoint so that the open end of the sleeve is 5/8 wavelength below the feedpoint, as shown in Fig. 12. The antenna now becomes a center-driven 1-1/4-wavelength dipole, which happens to be the "magic" length needed to produce power gain toward the horizon of 3 dB with respect to an ideal vertical half-wave dipole. This is the maximum gain attainable from a center-driven dipole, and is certainly worth getting.

Experimental measurements have shown that a single quarter-wave sleeve terminating the bottom end of the 5/8-wavelength antenna is insufficient to provide good decoupling of the coax cable below. Unlike the case of the decoupling sleeve on the base-driven half-wave whip, there is now an antenna current maximum at the top end of the sleeve. The decoupling is found to be only partial, and the radiation pattern shows degradation from the currents on the

Fig. 13. Commercial VHF version of marine antenna shown in Fig. 12. Here, the author provides temporary (and decoupled) support.

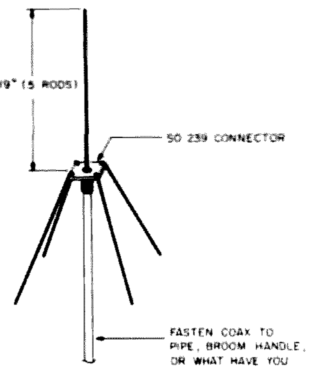

Fig. 14. The "famous" coat-hanger special.

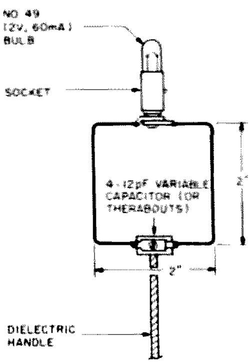

Fig. 15. An rf sniffer for the 2-meter band.

outside of the coax below the sleeve. The cure is to place a second quarter-wave sleeve below the first, as shown in Fig. 12. A commercial marine VHF antenna utilizing this construction is shown in Fig. 13. The upper 5/8 whip, the tuner, and the two quarter-wave sleeves are enclosed within a tapered fiberglass tube. The ratio of the diameter of the lower decoupling sleeve to the braid diameter of the coaxial line (RG-58A/U, in this case) is about 6 to 1, ensuring good decoupling.

This antenna produces a vertical radiation pattern very close to that of an ideal, isolated, center-driven 1-1/4-wavelength dipole in free space, unaffected by the feed cable at the bottom end. Another antenna based on the same principles has recently been announced for amateur radio service in the 2-meter band. It is designed for base station use and features twin decoupling sleeves of conical shape in order to obtain an adequately large mouth diameter in a rigid structure.

This article would be incomplete without a mention of the ideal antenna for the amateur who wishes to rush a 2-meter base station on the air on an absolutely minimal budget. This is the famous "coat hanger special," which actually *can* be made with coat hanger wire, and which performs spectacularly better than just about any automotive-type whip antenna when connected to the end of a length of coaxial cable. Fig. 14 shows the details.

This simple antenna, made on a UHF coaxial chassis connector, behaves like a vertical, center-driven half-wave dipole. Note that the 4 radial rods, referred to erroneously by many people as a "ground plane," are bent down at about a 45° angle from the horizontal. *Don't* mount these rods so that they extend out horizontally from the base of the whip. To do so will produce (1) a radiation pattern in which maximum radiation is lifted from the horizon, and (2) an input impedance of around 35 Ohms, resulting in a mismatch on a 50-Ohm cable. Bending the radial rods down at about a 45° angle (1) brings the maximum radiation intensity down to the horizon, and (2) brings the input impedance up to about 50 Ohms, giving an excellent impedance match. A low vswr over the entire 144-148-MHz band will be obtained.

Although a good antenna, the coat-hanger special is not the answer to all of the world's problems. It is driven at a point of current maximum, and there is no reason to believe that all of the spill-over current will be confined to the radial rods. Some current is bound to flow down the outside of the coax, and will produce standing waves of current, interfering with the radiation pattern of the antenna. The hope is that the 4 radial rods, being of resonant length, will hog the current, keeping the spill-over current along the outside of the coax small. To check your coat-hanger special, use your rf sniffer. If you detect appreciable rf on the coax below the antenna, try adding (or subtracting) about a quarter wavelength of coax to (or from) the feed cable. The reasoning behind this move is to try to make the outside of the coax change from an anti-resonant to a resonant condition.

The Rf Sniffer

The rf sniffer alluded to in the previous discussions is easy to build from junk-box parts. Even if one buys all of the components at a radio store, the total cost is unlikely to exceed $2.00.

The sniffer consists of a loop of wire, a pilot light, and a tuning capacitor all connected in series. The relative positions of the 3 components is immaterial. You can put the tuning capacitor right next to the lamp if you wish, or connect it in series with the loop on the side opposite to the lamp. I like to use a 2-volt, 60-mA bulb (No. 49) because this produces good sensitivity. The capacitor can be a compression mica-type, a ceramic variable, a tubular plastic variable, a miniature air variable, etc.

The dimensions of the loop shown in Fig. 15 are suitable for the 144-148-MHz band. The actual capacitance required to achieve resonance will be a function of the loop area and the wire size. By using No. 20 copper bus wire and the loop dimensions shown, resonance will be obtained somewhere within the range of 4 to 12 pF.

While the light bulb can be soldered into the loop, a socket is recommended. The bulb can easily burn out, especially when you are showing your friends how poorly their antennas are decoupled! It is also convenient to glue the sniffer to the end of a stick, plastic tube, or rod, to prevent your hand from detuning the loop.

Conclusion

This article can be summed up as follows: 1) There is no such thing as a one-terminal impedance; 2) A whip antenna cannot be end-driven successfully from a coaxial transmission line unless an appropriate decoupling system is incorporated in the design.

When the ham attaches an automotive-type whip to a length of coax line to serve as a base station antenna, he is doing so at his own risk. Ideally, the manufacturer or the dealer should call the attention of the buyer to the bad effects of this kind of misuse of the product. This is similar to the responsibility of a manufacturer of medicine to call the buyer's attention to the possibility of adverse side effects! A more serious situation exists in the case of some end-driven base station antennas, currently on the market, which totally lack any form of decoupling.

Armed with information gained from this article, and with your rf sniffer in hand, you should now be able to approach the marketplace with a more critical eye, asking the dealer embarrassing questions about spill-over and decoupling, and insisting on proof of performance! So much of the electronic equipment offered to the amateur radio buyer today is truly representative of the state of the art that it is high time that we elevate the antenna to this same status. ■

Introducing the 2m/220 Connection

—give crossband operation a try with this interconnection scheme

Carey I. Fisher WB4HXE
5428A Langhorn Way
Norcross GA 30093

With the introduction of 220 FM to the Atlanta area, I decided it was time to do some serious experimenting. I hope that the project described here will encourage others to use this fine band.

It all started when Neil Stone WB4UPC installed a 220 repeater and turned it into a remote base for 2m. While operating 220 through this system, a user can dial up, with a tone pad, any legal combination of 2m transmit and receive frequencies in 5-kHz increments. This capability, coupled with a good site, opens many possibilities!

After using this system a couple of times with a newly purchased Midland 13-509 from my home QTH, I wanted to be able to access it from my mobile. However, I also desired the capability of using a hand-held to achieve the excellent coverage afforded by the remote base.

Mounting the 13-509 in the mobile was no problem, but the question of using a hand-held required some thought since, owning a 2m hand-held, I did not want to purchase another. The solution appeared as if in a vision: Why not a crossband repeater?

With an IC-22S for the 2 meter end and the 13-509 on 220, all that was needed was some control and audio interfacing and my 2m hand-held could be used to get into the 220 machine. A block diagram of the system is shown in Fig. 1. This system was originally designed to be used in the mobile; however, it has also been used at the home QTH.

A look at the schematic in Fig. 2 will show how simple the audio interface is. Connections to the rigs' speakers are most easily made using the external speaker jacks. The mike connections can be made via either the front-panel connectors or the accessory jack on the back of each rig. The capacitor and pot values were chosen to fit the particular impedance and audio characteristics of the rigs involved. For interfacing to other rigs, general guidelines can be given. The pot should be approximately the same value as the mike impedance. The capacitor value can be experimentally determined for best audio quality.

Fig. 3 shows the schematic of the control section. While many variations of the transistor switches are possible, it seems that every time I designed one "by the book," it failed to operate properly. The circuits were finally debugged using a deterministic (read "cut-and-try") approach. One word about the use of relays instead of solid-state PTT is in order. While I am normally dead set against using relays in modern ham gear, two beautiful miniature relays were available in the junk box. Also,

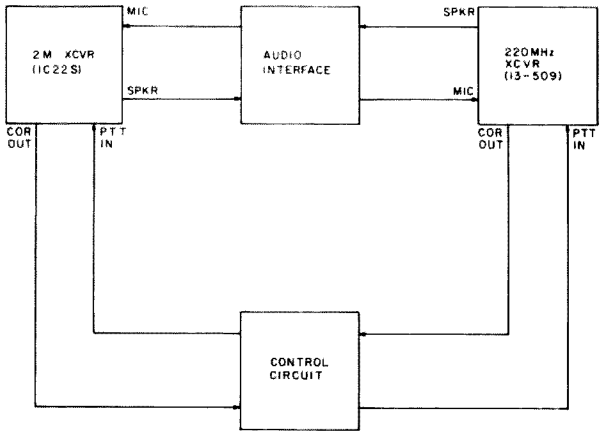

Fig. 1. Block diagram.

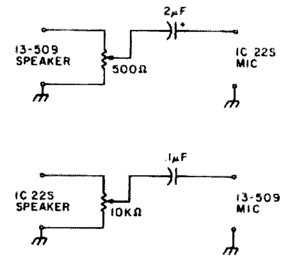

Fig. 2. Audio interface schematic.

"dry" relay contacts will switch any PTT system.

The connection for COR in the 22S was made at the low end of the signal light. When no signal is being received, this point is high, turning on Q1, which closes RY1, thus opening PTT to the 13-509. When a signal is being received, this point goes low, turning Q1 off, which opens RY1, closing PTT, thus repeating from 2m to 220. The "220 TRANSMIT" LED is also turned on by this relay.

COR from the 13-509 is taken from the collector of TR13. This is the noise amp switch and the collector is low when a signal is not present. This is the opposite of the operation of the 22S, so the relay, RY2, is wired oppositely, that is, the normally-open contacts are used on RY2 as opposed to the normally-closed contacts on RY1.

A bit of caution: Don't forget to include an on/off switch that disables both PTT lines or you will have one or the other rig transmitting when you don't want it to.

All connections to the rigs were made to the accessory connectors. This allows normal use of the rigs without cable swapping.

This crossband repeater controller has really added versatility to my 2m hand-held. I can park my mobile, turn this device on, and leave. From anywhere within simplex range of the mobile (I usually use 146.49), I can communicate through my hand-held, through this system onto 220, through the 220 to 2m remote base, and out on any combination of 2m frequencies. Using this system, I have worked over a hundred miles using a 5-Watt hand-held in North Georgia terrain that is almost impossible to communicate through in any other way.

220 has finally come to Georgia! ■

A Fresh Start for your Old Tx

—modernize it with grid-block keying

As a result of the most recent boom in amateur radio, many older pieces of tube-type equipment have been pulled out of the closet and placed into active service. My old Heathkit DX-40 occupies a prominent place in my shack and has been the workhorse of many hours of DXing and rag chewing. However, when I moved into the fast-paced Extra subbands, I found my hand key inadequate and decided to move up to electronic keying. I homebrewed the keyer with few complications. A reed relay was used to perform the main switching function. I plugged the keyer into the DX-40 and hunted my first victim on the receiver. Tragedy! The very first dit fused the relay contacts and the rig had to be turned off to terminate the transmission. I had obviously overestimated the power handling capability of the relay.

In cathode-keyed circuits, virtually the total input power of the transmitter is passed through the key (or keying relay). In the case of my DX-40, this amounts to about 150 mA at 600 V. The solution to the problem was obviously to use a relay with greater power handling capability (or was it?). A search for such a relay left me empty-handed. I could find no relay that was fast, cheap, fitted the voltage and power requirements, and was available locally.

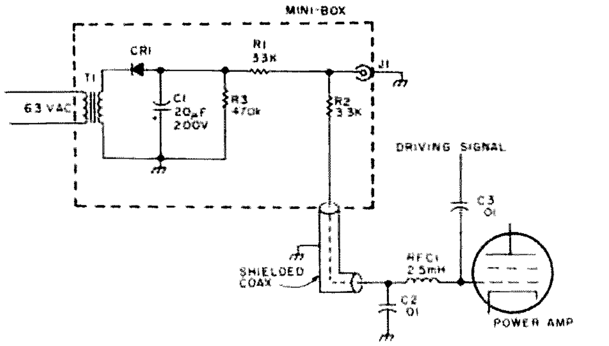

Fig. 1. Grid-block keying modification. C1—20-uF, 200-V dc electrolytic. C2, C3—.01-uF, 1-kV disc ceramic. CR1—200-V, 0.5-Amp silicon rectifier. R1, R2—1-Watt, 20%. R3—½-Watt. RFC1—2.5 mH. T1—filament transformer, 115-V primary, 6.3 secondary at 300 mA.

Finally, it dawned on me that there must be a way to key the transmitter without switching the full power of the transmitter directly. It did not take long to find a grid-block keying circuit in a old handbook. This type of keying requires the switching of only 150 V at a current of just a few milliamps. This was well within the limitations of my small reed relays and could even be handled by an inexpensive transistor. An important bonus in using grid-block keying is the reduction in potential shock hazards. Scrounging through the junk box, I found everything I needed for the project. In an additional hour and a half, I was on the air at 25 wpm.

The principle of grid-block keying is very simple. During key-up periods, the final amplifier is blocked by placing a strongly negative charge on the grid of the power amplifier tube. When the key is closed, this voltage drops across a resistor (R1 in Fig. 1). This removes the charge from the grid and the amplifier is free to run normally. Basically, the keying circuit is composed of a voltage source and dropping resistors. An isolated negative 150-V dc source can be inexpensively obtained by using a 6.3-V filament transformer as the main component. The transformer's 6.3-V winding is connected to the 6.3-V ac filament line of the transmitter. The original primary of the transformer then becomes the high voltage secondary. The transformer can be conveniently tapped into the filament line of the transmitter at the filament terminals of one of the tube sockets. Note that the rectifier is connected in such a manner that the ground is positive with respect to the negative keying voltage. It is important that filter capacitor C1 be connected properly with respect to this polarity. Also keep this in mind when making any voltage measurements. R3 is included as a bleeder resistor.

We now have a negative voltage source and a mechanism for turning it on and off. Getting the charge to the grid requires some special consideration. In my first grid-block keying circuit, none of the components was shielded. As a

a result, the transmitter emitted a signal during key-up periods. The emitted signal would gradually creep up in intensity until it reached almost full power. Placing the voltage source in a minibox and using coax to get the voltage to the power amplifier eliminated the problem. The driving signal is kept from entering the keying circuit by RFC1 and C2. The dc keying voltage is prevented from entering the driving circuitry by the .01 blocking capacitor, C3. If the grid is already dc-isolated from the driver by a capacitor, C3 is not needed.

It should be noted that the grid-block keying modification in my DX-40 disabled the "grid" function of the meter. This is only a slight hindrance in actual operation. Too much grid drive with grid-block keying will cause the transmission of a "backwave" or residual signal during key-up periods. Grid drive should be adjusted to the point where no plate current can be detected during key-up periods. The output could be checked with a sensitive rf power meter or an swr meter to detect any backwave that might be leaking through.

Most older cathode-keyed tube rigs are designed so that the transmitter is activated when the plug is removed from the original jack. Some designs may require that the jack be shorted. A word of warning: If you leave the original cathode-keying jack in the transmitter, cover it so that your keyer won't be accidentally plugged into this high voltage gap. I learned this lesson the hard way. You guessed it—I fused another relay. ■

An Inflation Fighter for 220

—join the fun . . . inexpensively

$18.50 and 90 minutes, and you're listening in.

Michael J. Clarkson WA3HWG
RD 4
Export PA 15632

How would you like to be on 223.5 MHz for a nominal investment of $18.50 and an hour and a half of your time? Well, I think this article may help some people who are stymied right now about the whats and wherefores of how to get on, seeing that there is no surplus equipment available and "scanners," per se, don't cover that area of the frequency spectrum.

For some 6 months now, a few of us hams here in southwest Pennsylvania have been fooling around with 223.5 MHz. Even with the availability of some Midlands, Cobras, and FM 76s, the activity is very sparse. As many of you are aware, VHF Engineering sells rf decks for 10 through ¼ meters. These modules are easy to build and tune up, and they are inexpensive. They also have, as a standard feature, an output of 10.7 MHz as an i-f frequency. Now, think about that for a minute! What else uses 10.7 MHz as an i-f? Well, almost all scanners except Bearcat and some Lafayettes. Also, almost all 2 meter rigs do. So, if your already own some sort of scanner (and a lot of hams do), $18.50, and a little time, you are in the listening business on 220 or 440 or 50 or 144 MHz.

All you have to do is wire in the output of the VHF Engineering rf module to the 10.7 MHz i-f in your scanner or 2 meter rig and you are ready to go. This modification does not alter the performance of the scanner or 2 meter rig, but enhances it by adding, in this case, 220 MHz capabilities. You can even use an old portable AM-FM radio which has its i-f at 10.7 MHz. The gain in these sets is not very great, but they will work.

To be more specific, in my own practical application I bought a VHF Engineering 220 rf module, built it, and needed a 10.7 i-f—preferably another stage at 455 i-f—and an audio and squelch stage. So, considering what to do, I spied my much-experimented-with, obsolete, Radio Shack Pro 4 scanner, which is a pocket monitor for VHF frequencies. With a little investigation, the first i-f 10.7 MHz ceramic filter was found, and I injected the output of the rf module in there. "Voilà, it worked!" So for a very modest investment, I now hear quite well on 220.

Another idea would be to inject the output of the module into any 2 meter FM rig having an i-f of 10.7 MHz. I tried the above-outlined procedure on my own Icom 22S, and it works great, with very good sensitivity and gain.

A VHF Engineering 220 transmitter goes well with my setup. In fact, I am contemplating building a 220 walkie-talkie utilizing these ideas. ■

Building Long Yagis for UHF

—some pitfalls to avoid

Beware of the "something for nothing" offer! With this thought in mind, the long yagi antenna is being placed under suspicion. Would you believe a 48-element collinear array (24 driven elements and 24 reflectors), whose gain is approximately 16 dB, could be replaced with a single 13-element long yagi? In addition, the long yagi has: 1. Less wind resistance; 2. More directivity per pound of aluminum; 3. Greater ease of fabrication; and 4. Excellent mechanical stability. Certainly there is a temptation to believe that the long yagi antenna offers something for nothing when compared with other antenna arrays. What must be sacrificed to obtain the aforementioned advantages? Followers of the "Collinear Clan," read on!

The cautious amateur constructing a beam antenna intended for application in the VHF and UHF range would exhibit a tendency to cut the elements longer than necessary. This stems from the old adage, "It is easier to cut 'em long than to add a piece on." This is the philosophy that has helped give the long yagi a questionable reputation.

In an attempt to reinstate the long yagi in its rightful position, antenna patterns of a 13-element yagi were made. Fig. 1 shows polar patterns of the long yagi in horizontal polarization. Fig. 2 shows patterns with the yagi vertically polarized. Fig. 3 shows the reference dipole in the horizontal plane. Curve A is plotted in the same relative gain scale as

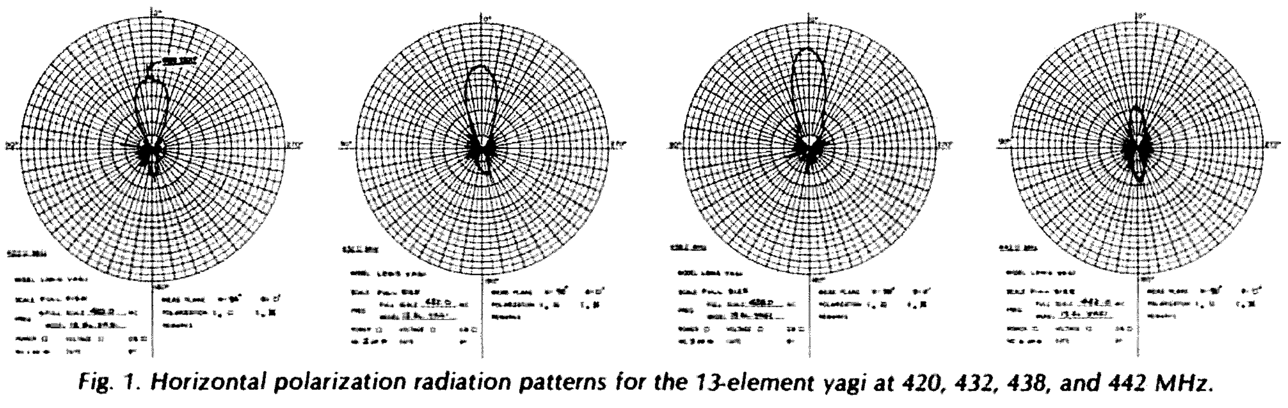

Fig. 1. Horizontal polarization radiation patterns for the 13-element yagi at 420, 432, 438, and 442 MHz.

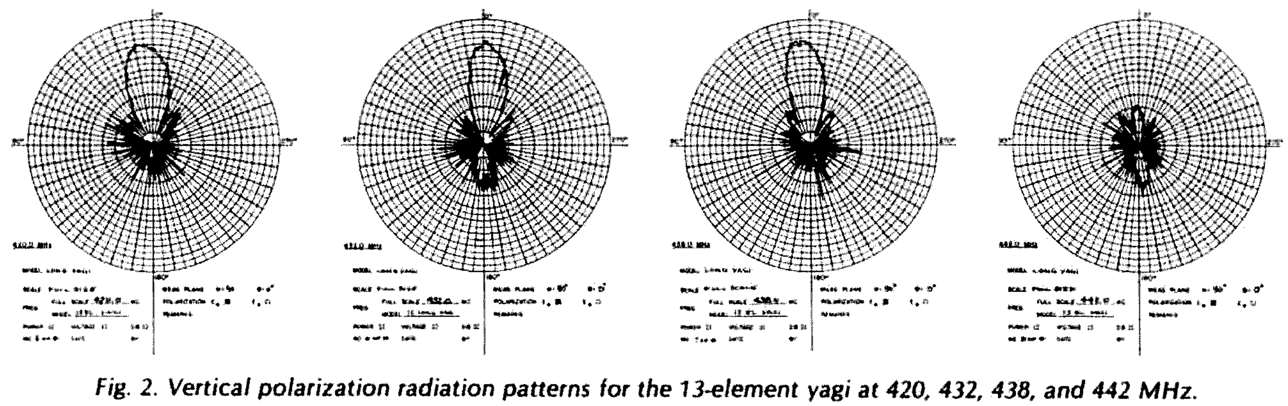

Fig. 2. Vertical polarization radiation patterns for the 13-element yagi at 420, 432, 438, and 442 MHz.

Figs. 1 and 2. Curve B is merely an expanded plot due to gain increase in plotting technique. The spike at the upper-left of Fig. 1 was produced by a search radar of an adjacent airport. A cool, windy fall day and the lack of more output from the signal generator kept the patterns from being of the picture-book variety. Fig. 4 shows the test setup.

Fig. 5 shows graphically the nonsymmetrical bandpass characteristics of the long yagi-type of antenna. The extremely rapid cutoff on the high side of the intended operating frequency has caused many an amateur to cast aside this type of antenna. This curve shows readily that it is unwise to cut the antenna to operate below the intended operating frequency.

The 438-MHz pattern in Fig. 1 indicates that the beam width at the half-power points is approximately 25 degrees. Gain measurements further revealed that 16 dB of gain can be realized without difficulty. This gain figure can be obtained over a frequency range of at least four megahertz. Four megahertz is approximately plus and minus 0.5% of 435 Hz, which is more than ample for ham frequencies. Just make sure that your beam design frequency is at or near the high end of the bandwidth desired.

Four long yagi antennas (Fig. 6) operating on 432 Hz, using 13 elements each, will yield a gain of 22 dB (assuming 16 dB per each 13-element yagi). To obtain this same gain with a collinear array, approximately 176 elements would be required (88 driven elements and 88 reflectors). At this point in comparison, does the singular feature of unnecessary bandwidth seem worthwhile?

If reasonable care is exercised during construction (Fig. 7) and *all* dimensions are adhered to within one sixteenth of an inch, then you can boast, "Have yagi, will radiate."■

Working with FETs
—part I

When it was introduced, the FET was billed as "the transistor that thinks it's a tube." There's been a lot of current through the gate since then, but there are a lot of similarities.

It is one of the few transistors that does give a hard-line tube man a fighting chance at making it work.

There are a few basic differences. The voltage, current, and power ratings are much less. You also lose one important tube advantage right off the bat. The trouble with thinking of the FET as just a teensy tube is that it really just thinks it is a tube; it really is a transistor.

As with almost all transistor situations, they are unforgiving of errors. With a tube, you can make a mistake and probably you won't hurt the tube if you were paying attention and correct it. Transistors either get treated right or they quit on you. That's it. There is rarely any middle ground.

In that one sense, the FET is a transistor, not a tube. While you probably can understand that the operating conditions are at a much lower level than a tube, it may be hard to get away from the tube thinking you are used to, which can harm the FET.

Circuit operation has a number of similarities between the FET and the tube. If you did much bench work with tubes, the circuits will not be far different. The thing you have to catch on to is the trick of treating it like a transistor. A few simple precautions should be enough to get you going.

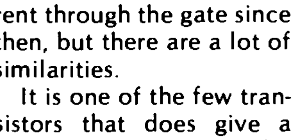

Fig. 1. Schematic symbols.

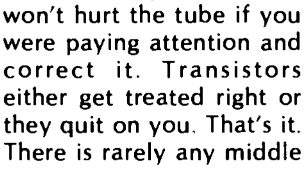

Fig. 2. Simplified tube AFSK oscillator circuit.

There must have been a time when you were told not to connect the plate supply to the filament, and what would happen if you did. Somewhere along the line you probably did it, too. That's how you learned not to for all time. FETs are much cheaper than the tubes were even then, so it's not too traumatic to lose a few learning. Let's just try and cut down on the number.

First, a few terms. Fig. 1 shows a triode tube schematic and an FET schematic, with a comparison of the terms for the elements.

While you probably did not have to think much about the safety of the tube while you worked, you did have to think of your own safety. Those high voltages could kill you if you didn't keep your wits about you. One of the unfortunate things about working with transistors is the tendency to forget about safety. At those low voltages, a serious accident is rare. You can still get hurt, though. There is also plenty of kick in the line voltage of your power supply. Still, most people tend to get careless working with transistors; and they usually get away with it. All this talk of safety has a purpose.

Besides saving your own hide, a little common sense safety-thinking can save your transistors. With FETs, there are things to watch for. Here I am speaking of the normal run-of-the-mill three-element FET, not the MOSFETs or other exotic breeds. Just your average FET. They have a few weak spots. Some of them I learned about the hard way. Let's start with a few of those nasty parameters.

The FET has a maximum safe voltage that can be applied to the drain (plate). It also has a maximum safe current; this is just about

the same as with tubes. There just is less chance of recovery if you go wrong. There is one other basic maximum. This is the safe voltage that can be applied between the source and the gate. There is a comparable safe grid voltage with a tube, but it was not something that you ran into often. What this all gets to is that it is often fairly simple to adapt a tube-type circuit to an FET if you just watch out for the ratings.

The FET audio oscillator to be described is almost an exact duplicate of a tube circuit. However, there are certain key factors in its design that are a direct result of its being an FET rather than a tube.

Some of the guidelines for working with the circuit were learned the hard way. Once learned, they can be adapted to working with other FET circuits, as the safety factor is the same no matter what the circuit function is.

The basic tube circuit started life as a simple AFSK circuit. A double triode was used as an oscillator buffer circuit. Since the oscillator part was so simple, it was chosen for the FET circuit. The basic circuit is shown in Fig. 2.[1] This is much simplified. The AFSK part was left out, and only the oscillator part is shown. This can be transferred to the FET, but, in fact, it was not done that way.

I like to see how many parts can be left out and have it still work. (It usually works better that way, too.)

What was first tried was something similar to Fig. 3. At some point, fiddling with values, it did work. Now my education began.

The output at the drain was not much to write home about, and the waveform was no great bargain. There were, however, two basic considerations working here. I was carefully monitoring the current the FET was drawing, the output waveform and voltage, and the dc voltage at the drain. The one thing I wanted to be sure of was that I was not exceeding the drain voltage or current. Since both were quite small, and well within limits, it was just a question of getting the waveform and output right.

Then the fun began. With a little more work, I managed to go through about ten bargain FETs. I kept my eyes glued to those meters and that scope; I never even got close to the ratings. What I did get was ten zapped trannies and a bad eye twitch. There had to be something I was missing.

Then the great light dawned. I was zapping the input. But how? With such a dinky current and output how could I zap the input?

There were two answers here. The el-cheapos did not have the same between-element ratings of the HEP801 I also was using, and the input circuit is where the action is.

This is going to sound strange, but when I got around the measuring it was startling. Even in the original tube circuit, the output was taken from the grid circuit. That's where all the signal is. That was where all the trouble was in my FET oscillator, too. A simple matter of peak-to-peak was killing me.

Now we have to go back a bit and see what is happening in the gate (grid) circuit. Let's start with my power supply. It is adjustable, and I was testing at 5 through 12 or more volts dc to the FET. That's a normal transistor range, and I even gave it a bit more for test purposes. It was about that time when I began to notice a distinct lack of functional FETs. Since I obviously (?) was not exceeding the ratings, it was quite upsetting.

Having nothing left to do, and only one FET left, I went and took a look at the gate circuit with the scope. It nearly knocked me off the chair. The scope had been set for a small signal, and the gate signal nearly punched a hole in the top and bottom of the CRT. Where did all the signal come from all of a sudden . . . and how do I get rid of some of it?

That was the problem, once I recognized it. Then a few facts filled in the rest. First off, I turned off the gear until my head cleared. While it was obvious that there was a walloping signal in the gate circuit, I had not fully pinned it all down. I could see that there was a probability that I was zapping the gate though, so I went back to the spec sheets. The specs for the 801 FET showed a maximum of 20 volts difference between the source and the gate. If this were exceeded, it would damage the FET. There went a handful of FETs.

That was what happened; but why, and how do I avoid it next time? It was obvious that more testing and measuring would have to be done, so there was going to be a risk.

The first obvious thing to do was lower the supply voltage. This was done and the scope watched while it was turned back on. At some lower voltage, the circuit started up again. A quick check of the scope showed that the signal voltage was safe. Then a few measurements gave me the data. The signal voltage is a peak-to-peak sine wave. A peak-to-peak signal also will count as the maximum value, too. Thus, even though the specs imply a dc difference of potential not to exceed 20 volts, a sine wave more than that also will be a difference exceeding 20 volts.

There is another factor here, too. The signal voltage can approach twice the value of the dc voltage to the drain. In an oscillator circuit, the coil and capacitor can store a charge that will add to the charge of the opposite swing of the wave. That means a nine-volt supply voltage can deliver almost an eighteen-volt peak-to-peak signal. Go up to 12 and you get 24 volts p-p. Test it at 15 volts, and your 30 volt signal zaps the transistor.

The first thing you can do is keep your power supply voltage low. But what if you want to run the oscillator at a higher voltage, say 12, for mobile use or to go with other circuitry?

The obvious thing would be to dampen its enthusiasm. There's a simple way to do this. Just add a resistor across the circuit as in Fig. 4. The value isn't critical. Just watch the scope as you play with values (an ideal place for a resistance substitution box).

By loading the circuit, you cut down its output. I settled on a value of 2.2k

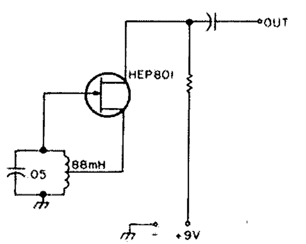

Fig. 3. Experimental FET oscillator.

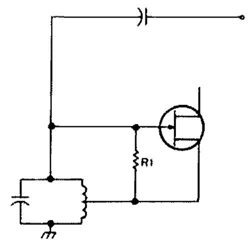

Fig. 4. Resistor added to cut signal.

for one circuit. That gave me an output of about 11 volts p-p with a drain current of 2.2 mA. My notes show a voltage of 9-12 volts, but that is just nominal. The circuit was tested and worked at both lower and higher voltages.

In the final circuit (Fig. 5), there was no load resistor. It seems to work well without one. There was one additional part that might be needed.

With some circuits there may be some TVI or RFI caused by the unshielded circuit or long test leads.

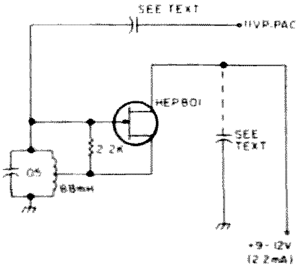

Fig. 5. Practical FET audio oscillator circuit.

When you get it going, try a few values of bypass capacitors at the drain. Too big a value will stop the oscillator from working. Too small will not filter, but there should be a range of values that will do the bypassing job. Start around 0.005 to 0.5 uF.

That brings up an important point. There are several performance characteristics you want to have in your oscillator. These are simple things that tell you the design is sound. You will hear a good tone, even if there is distortion that would be unacceptable for many purposes. The scope will show you the actual waveform of the output. What you want is a good clean sine wave output. Noticeable clipping of one or more peaks usually will give you harmonic content that can cause trouble. So for openers, it should look right.

It is not shown here, but break the source lead and put in a key. Then key the oscillator as a code oscillator. If it does not key well, your circuit is not the best. That's one reason I did not follow many standard designs; they did not key well. This one keys cleanly and starts right up. At the least you can use it for code practice.

There are some simple stability tests. Leave it on for a while. Does it drift as you listen? A low frequency tone is best for this; a slight frequency shift will be more noticeable at low frequencies than at higher. An obvious short-term drift is a sign of poor design or of circuit trouble. A hot or warm FET is another trouble signal. If you have a counter or some other standard, you can check also for long-term stability. However, make sure your standard does not drift, too.

If your circuit shows good form, does not change characteristics over a long-term test, and keys cleanly, you probably have a usable circuit.

Another tip-off is your tolerance factor. This circuit will work over a wide range of parts values and voltages. Beware of any circuit where values are critical for operation. That does not mean don't use precision where you want it—for example, to get an exact frequency—but if the oscillator is critical in operation, it will be trouble no matter how precise it is.

Remember that your output is taken from the gate circuit. Almost any normal coupling capacitor value will work. 0.05 uF to 10 uF would be median, although I have coupled the output with a gimmick capacitor of a few turns of wire.

The pitch is easily adjusted over the audio range by the choice of C1. A capacitance substitution box can help here, though I have used just a handful of caps and done as well.

While this is a simple circuit, there were a number of very important guidelines for working with FETs. These will be restated as rules of thumb.

1. Do not exceed the maximum drain voltage or current.

2. Do not exceed the maximum voltage between elements, particularly the source-gate junction.

3. Monitor all key voltages and signals.

4. Start at the lowest practical drain voltage and work your way up.

5. Leave yourself the largest margin for safety you can.

6. A critical circuit should be a tip-off of poor design.

I found the final circuit I used to be reliable for most of my purposes. I think it can be adapted easily for many ham uses. A little time working with that circuit should make you much more comfortable when working with FETs. The circuit is not the only one in the world; however, a great deal can be learned by trying other tube-type circuits with your test set up. Some will work right off, some you may have to fiddle with values or change the circuit around some.

In any case, there is no substitute for the pragmatic experience of actually working with these circuits, and having first-hand knowledge of what happens as you vary values or circuit configuration.

I hope these circuits and test methods shown will encourage experimentation with this and other published circuits. ■

The MARC Success Story

—your club can do it, too!

Bob Heil K9EID
Box 68
#2 Heil Industrial Drive
Marissa IL 62257

Radio clubs can be fun. Radio clubs promote and increase the awareness of this great hobby of ours. Radio clubs generate goodwill and fellowship among our ranks. Radio clubs become effective and successful only in major cities with large populations.

All but one of the above statements are very true. The last statement will get blown to the wind as you learn more about MARC, the Marissa Amateur Radio Club. This club celebrated its first anniversary last May. It has a roster of almost ninety members. Its monthly meetings average fifty in attendance, and each month its programs and special events keep drawing the members closer and increasing the activity. The club owns a massive repeater system with wide-area 150-mile coverage. Every Monday night a highly successful "Swap Net" is activated by MARC on the 81/21 repeater. MARC has been active in two Field Days, has sponsored two March of Dimes Walk-A-Thons, and has graduated many through its license classes. A code practice session is run each evening on the repeater.

This scope of activities is remarkable for a club located in a small town like Marissa, Illinois, fifty miles southeast of St. Louis in the middle of the southern Illinois coal fields. The population of Marissa is 2400, when counting all men, women, children, and pets!

Humble Beginnings

In April of 1977, Dick Smith WB9VZE and I began discussing the idea of a club for the area. Steve K9SR had been holding classes in his home and had helped many in obtaining the knowledge necessary for them to get their licenses. Dick and I called an organizational meeting to see what kind of interest and support for an area-wide club would be generated. That first meeting was attended by Bernice WD9CXQ, Floyd W9ZVT, Windell K9ZQK, Bud WD9WFX, Scot K9SF, Dick WB9VZE, and me. As it turned out, the seven of us chartered the club.

Making It Happen

It was agreed that the best way to really promote MARC and give the area amateurs a gathering place on the air was to build a repeater. I took on the project. Hundreds of hours went into building not "just a repeater," but a complex system that turned out to be one of the finest repeater systems in the Midwest. Jim WA9FDP (builder of the 22/82 in Gillespie) gave Dick and me a new Motran receiver, Lloyd WØLLC gave us a new Sinclair antenna, Floyd W9ZVT donated a small power amp, Gus K9EBA supplied the rack, Paul WB9IGB aligned the transmitter, and Hank WØCZE donated a Midland link transceiver. The club continued to promote donations, gifts, and help. The Peabody Coal Company gave permission to use one of their 250-foot silos for a remote receiver site.

Dick and I got the biggest boost from the Village Board of Marissa. We attended a Board meeting to explain how this repeater would be effective in emergency communications, as well as in promotion of the city of Marissa. We left the meeting with a $250.00 check and a terrific repeater location, rent-free, atop the First National Bank Building. One final donation came from Dow Com, the southern Illinois Wilson distributor: a brand new 60-foot crank-up tower!

All the pieces were assembled, and 81/21 was on the air! Bernice, Floyd, and Windell were spreading the word. MARC was happen-

ing! Club meetings, OSCAR slide shows, demonstrations on antenna phasing, birthday parties. If you don't show up, you really miss something! The meetings *are* happenings!

A great help was Ernie WB9TDC, who set up a raffle of a new Hy-Gain HT. Many tickets were sold by all club members, but Ernie really promoted those tickets. With each ticket came more support for MARC. Membership increased and the meeting room at the bank was outgrown, so meetings were moved to the new Community Center. Memberships continued to roll in; each and every ham was proud to be a MARC member.

This same warm, country atmosphere was projected onto the repeater. The members of the "Double M" (Marissa Machine) are, without a doubt, one of the most friendly, fun-loving, and helpful groups on any repeater system.

Newsletters

In December, seven months after charter, our club trustee, Tania WB9TKC, and Bernice WD9CXQ produced the first monthly newsletter, *Harmonics*. The newsletter has become one of the key factors in keeping the present members informed, as well as introducing the club to prospective members. Tania has the cover page offset-printed, so pictures of club members and events can be published, as well as small construction articles, reports, and useful information normally not found in the regular magazines. No one element or person can be credited with the great success of MARC, but the promotion and communication constantly provided by the newsletter certainly help.

Maintaining Interest

What all of this can mean to your local club is that there is no need for a club to stay dormant. Amateur radio has so many facets to keep the members interested. It is up to each of your members to contribute something, even if it's a simple mention of the club on the air.

There are simple programs that can generate fantastic interest and enthusiasm. Here are a few ideas for your next club meeting.

Ask a local Motorola or GE sales office about a speaker to explain some new communications development or alignment technique.

Find a police department radio technician to come and explain its sophisticated radio system.

Your CD office, Civil Preparedness Office, armed services, or Weather Bureau will be pleased to explain disaster and evacuation techniques.

Railroads have fantastic slides and programs to explain hazardous materials handling, radio communications, or general routing.

Airline or FAA radio technicians can talk about their communications systems and control operations.

Look for a collector of antique radios to bring some of his collection for nostalgia night.

Local ham radio stores are always willing to demonstrate some SSTV, video RTTY, or video CW equipment.

AMSAT directors love to discuss OSCAR.

The list is endless! These are some of the things it takes, month after month, to promote those meetings. You must get the members into the habit of setting the second Tuesday (or whatever day) aside for that important radio club meeting. You must entertain or inform them. They must want to return. It's the activities director's job to see that this is done.

Home-Grown Programs

Sometimes clubs are unable to contact outside speakers to present a program. To fill a void, here are some ideas that members themselves can use to put programs together.

Have a Home-Brew Night (no Kentucky moonshine, please!). Ask any and all to bring their best attempts at building equipment. Award a ribbon or small trophy for the best—or worst.

QSL Night—see who has the most DXCC, VHF, counties, longest distance, oldest, etc. Again, give awards.

Antenna Gain Measurement Night—bring your home-brew VHF antennas, and award trophies for the best.

Fix It Night—bug a few radios or keyers and see who can find the faults.

Grid-Dip Night—wind some coils, check their frequencies, show how to check antenna resonance, and so on.

Those of us who have been around for awhile sometimes forget that the newcomers have not seen or heard a lot of the "take it for granted" things. These simple things can be turned into fantastic programs. Talk about feedlines, show them how different types of coax work better, or worse; discuss design. Be original. Be innovative. Keep it simple and *fun*! Always acknowledge the oldest license, the guest or member from farthest away, the one who can operate the most bands or modes.

For a surefire barn-burner meeting, celebrate a member's birthday, but keep it a surprise. A surprise party can really be a great amount of fun. Keeping the secret is difficult, but can be done. Just think of the crazy gifts you can rid your junk boxes of!

Selling donations to the club in the form of chances on handie-talkies, keyers, antenna systems, etc., can be very successful as well as a heck of a lot of fun. it gets to be an "in" thing for all of the members to buy their tickets so they won't get left out. With enough promotion, the meeting you select for the drawing can really be turned into a mini-hamfest.

Public Activities

The club has to keep the public informed of its existence. Local newspapers love to have articles about your meetings or activities. Exposure to the outside world can be achieved by setting up portable stations in shopping malls, grocery centers, schools, and service clubs (Lions, Rotary). Many times you can solicit donations at these outings, also. Try to have the local TV mini-cam, radio station, newspapers, and magazine reporters on hand to report on your activities. Traffic handling, OSCAR, phone patches, and, best of all, SSTV, can be effective in attracting attention. Don't forget to hang *big* signs with the club logo (You don't have one? Shame!) or name predominant, as well as names and phone numbers of those members who can sign up prospects for Novice classes. Advertise your local repeater frequencies. You won't believe how many VHF scanners are out there just waiting for amateur radio to inhabit the speaker!

It is up to you and your club. Do you really want bigger and better membership? Do you want to have more fun? Do you want to expand each member's awareness and knowledge? The MARC has proven that all of this can be done in a village of 2000 people. The best part of this is that the entire effort can only benefit amateur radio everywhere. ■

Want to Upgrade? Take a Tip from a Ham Who Did!

—previewing the new code test

You should upgrade. It's easy. I'm writing this to encourage you. If I could pass and upgrade to the Advanced license, so can you. Let me explain.

In the Los Angeles area, one can attend Murphy's Radio Class. This class increases your knowledge and ability to pass the theory and regulation segments of the FCC tests. Also, Murphy's sells code tapes to help you pass the 13 wpm requirement. Other cities probably have similar classes and aids.

So now we are down to the crux of the problem: code, code, code, 13 wpm, 13 wpm, 13 wpm. That does not sound like much. But it takes study and time and effort and is well worth it.

I got up about one-half hour earlier each morning to study code. Also, a local repeater was broadcasting the Murphy tapes 3 or 4 nights a week. They were so helpful to me that I finally bought a set. Then I made progress to about 10 wpm. It took the 13+ wpm tape by *73 Magazine* to push me over the magic 13 wpm. The tape from *73 Magazine* was mind-stretching and of great help.

I was cool, man. Psyched up and all that. No way will the FCC cause me to falter. The 13 wpm will be a breeze.

On a nice Wednesday, I studied in the morning, ate a late brunch, and drove to Long Beach, Calif. I parked my pickup and walked about 3 blocks. Nice day. Nice sun. I was cool, man.

I arrived at the FCC reception area on time, about noon, and that's about an hour before anyone wants to get serious at the FCC. So now I cooled my heels. Being cool, man, I read a *Reader's Digest* and acted nonchalant. No code test is going to get me down.

While waiting, one episode was interesting. A young man asked if I was going for my Extra, probably because of my grey sideburns. No, I was not, but I could help because I am an electronics engineer. His question concerned microvolts at the half-power points from an antenna when given microvolts at the center of the lobe or beam. Be careful here to calculate in microvolts, not Watts. A factor of 0.707 enters. Such final reviews are common while waiting for the tests to start. Later I saw the young man taking the Extra written test, so he had passed the 20 wpm test. Good for him.

Finally, it was my time. The group for 13 wpm was called. We filed in, adjusted earphones, and waited. A young lady said we should copy down everything we could. Since the code test is one of comprehension, anything could help to select the correct multiple-choice answer. I found that to be very helpful and the FCC people friendly.

Then the palpitation commenced. My heartbeat went up. My breath came in short pants. My hand shook somewhat. And believe me, I'm serious. I had been psyched up. I had been cool. Yet the Funny Candy Company had reduced me to a driveling idiot and the test had not yet started.

During the one-minute warmup run, I copied about 50%. This indicated I was about to fail miserably. Naturally, this did not calm me. In fact, if anything, I was ready to quit then. But I was tangled up in the earphone wires, so I decided to stay.

The test began. W4— was talking to WA4— or close to that. Then there was something called RST. I figured that was CW short for RUST. The trouble was, some numbers followed RUST, so I dutifully copied them down. Lucky for me that I did. They had the nerve to ask me later how much RUST there was. So I picked 479's worth, and that was right.

Some guy named Fred was . . . and about there I blanked out and lost a whole string of stuff. But I did pick out two Rs in the middle. Keep them. May be useful later.

As things progressed, old Fred turned out to be 43 years of age and lived in Some City, USA. He

worked as a cowboy in Alabama or somewhere. Also, the weather was wet and windy.

The test proceeded to consider technical things like antennas, heights, tubes, rigs, etc. The rig I copied was an HQ-101 followed by something, something, something. I shifted my brain to zero and picked only an 8 out of the whole mess.

Finally, the pain subsided. Some 73s and old W4— signed with WA4—, but my palpitating heart did not slow. The FCC lady passed out the questions. Questions have never bothered me, but the answers do.

The first question said the two stations were W6— and W8— or W5— and W1—, etc. Not a mention of a W4 call. So I moved on to the second question. Aha! Weather! Once again I had four choices, but none was wet and windy. The third question also was from left field. It did not relate to my copy. Oh well, if I could answer all 8 of the remaining 7 questions, I could still pass.

I got up, not to leave in dejection, but to ask if I had received the correct questions. The kind FCC lady checked the cassette tape in use and told me #203 was correct and I should proceed.

Ready to quit, I stole a glance at the top of the question sheet at the next desk. The number at the top truly was #203 preceded by 12. My sheet had a preface of 20. So, back to the nice lady who finally gave me the correct 12-203. Aha! Now W4 and WA4 were involved, but by now my heart was more than palpitating.

The rest of the questions were straightforward. The other person's name was Randy, Rocky, Rory, or Rindy. I had copied only the name Fred plus two Rs in a monstrous gap. So obviously the two Rs had some relationship to Rory. So I marked it.

Later, I had to identify the rig transmitting. That should be easy. I had clearly copied HQ-101. Eagerly I searched for an HQ-101 answer. By golly, there was one—in fact, there were two. One had 14 tubes, while the other answer had 17 tubes. I had copied no tubes in my panic. But I did have the random 8 in the middle of a second tremendous gap. Well, 8 is fairly close to 7, and certainly a long way from a 4. So I guessed the answer as an HQ-101 with 17 tubes, which was correct. See how easy it is to pass?

Completed the test. Turned in the papers. Knew I had failed. Takes 8 out of 10 to pass. Heart still pounding. Oh well, I can come back in 30 days and try again.

Time clanked by and I was not thrown out on my ear. Maybe I had passed. Finally my name was called. I went into the next room to hear, "You passed."

The story above is true, but changes were made to disguise the FCC questions and answers. It had a happy ending. I qualified for the Advanced license. But the code test could have been a breeze if I had followed one simple rule: Concentrate on one character at a time. Worry about the words and the meaning after the test. Either of my lapses could have caused me to fail. Both occurred because I began to think about the words and lost my concentration. So concentrate and win your new license.

Remember, the people at the Funny Candy Company are okay and helpful throughout. So study and good luck. You, too, can upgrade. ■

A Microwave Primer

—waveguides, X-band, and other fun stuff

If one inspected the frequency assignments to amateur radio which lie in the spectrum above the ultra high frequency (UHF) region, one would find thousands of megacycles are available. Much of this spectrum is unused by radio amateurs; only small portions are occupied and then only sporadically. Some of these bands are shared by other services.

The thrill of communicating over very long distances on these frequencies is experienced by few amateurs and is reported and read by an equal few. What is it that makes this part of our hobby so compelling to those few that they will continue to experiment when there is little company on these bands? Why aren't there more experimenters? Perhaps you think that the equipment is expensive, or that construction is difficult, or maybe you can't find information on how to implement a microwave project.

The expense in implementation of a microwave station is not as great as some of the equipment costs for an HF or VHF station. The components are a little more difficult to acquire, but are available via surplus or from microwave component manufacturers. As for information on construction and operation, an abundance of information has been published in amateur radio journals for the last 40 years and much more is available from technical societies through the papers they present.

How does communication differ from that found on the lower bands, and why should you be inspired to try your hand at using these frequencies? These questions are easy to answer. A microwave QSO, depending on the mode used—and there are many modes available that can't be used on the lower bands—rarely if ever suffers from QRM. QSB and QRN, sure. (Anyhow, microwave QRM might even be a pleasure to hear sometimes!)

Most of the operations at W1SNN have been either FM or pulsed CW, and in most cases the signals were dead full quieting at each end of the circuit. It is true that the QSOs require an expedition to a high point, and a great deal of work goes into the project, but go out in the field on a Field Day and work five states and numerous sections with other stations and then see who has the highest multipliers. Most of all, the work is forgotten when you realize that the power levels transmitted are in the tenth of a Watt to a Watt level, into a three foot dish, and the guy you were talking to using similar equipment was forty or fifty miles away on top of a mountain that you couldn't even see.

Well, now that I have extolled some of the great things about working microwaves, I suppose you might like to know what microwaves are.

The name, microwaves, has been given to those frequencies which fall into and above the UHF spectrum. Who named it microwaves? I suspect, but cannot authenticate this, that it was so named during the early part of World War II when radar was coming into its own. Perhaps the

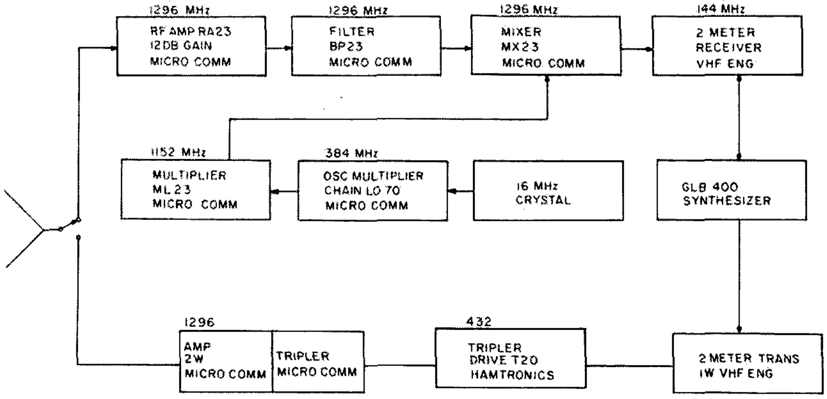

Fig. 1. 1296-MHz transceiver.

security measures which gave the *various* bands letter designations during this conflict brought the name into use. At any rate, it is a good name for the spectrum which, as we proceed to examine it, will be seen to include wavelengths of some frequencies we can use as amateurs which are hardly as long as the word microwave itself.

Let us examine how the Federal Communications Commission has assigned band nomenclatures to the radio spectrum and also how microwave equipment manufacturers have retained the WWII designations.

The FCC has assigned band numbers and lettered designations as nomenclature for all of the electromagnetic spectrum. The frequency allocations that are assigned to the ham bands are known to us by their designations, VHF, UHF, VLF and others. (See Table 1.)

The designations in Table 1 are found in the Rules and Regulations part of many of the commercial license examination question-and-answer books. Notice that the way they are grouped falls in line with the metric system, and that if the metric equation is worked out to become meters in wavelength, it falls in decades. Either way, it's easy to remember after a slight bit of study.

Further examination of the other tables may open your eyes to several facts about the bands that we occupy and rarely think about in terms of how they are located in the radio spectrum.

Table 2 shows how the HF spectrum adds up to the number of megacycles that we as *amateurs* occupy. When one examines the dial of the station HF receiver, the number of bands and the spread of them over the dial make it look vast. The frequency ranges are in very small steps from 160 to 10 meters in most receivers, but when the total number of amateur frequencies is added up it's only 3.5 MHz total coverage out of thirty—a little more than ten percent.

Some of the small nations that will attend the World Administrative Radio Conference (WARC) are of the opinion that, although they have a very small population in the vast high frequency sea, they now will need more. When they band together with their 1 vote-per-nation, they are going to be a formidable group, looking at our 10% as something they want—and may get.

Why bring this up? Let's look further at the number of megahertz we have available in the high frequencies. The total up to the end of VHF assignments, that stop at 1¾ meters, is 20.5 MHz. If we go on up into the microwaves, the total number of gigahertz that we have is 23.290 (see Table 2). Out of this, very little is used by amateurs. The ¾-meter band is used quite a bit for repeaters, and 1296 MHz is really catching on these days as are many of the frequencies up through 10 GHz, but not enough. It looks as if we could lose a lot of spectrum simply because we do not lay claim to it by enough use. These frequencies are very attractive to the 40 or more nations who will certainly exercise their combined single votes.

When you look at Table 2 again, you can see that the total number of gigahertz, not megacycles, is listed at 23.290, and the last assignment, which starts at 300 GHz, isn't listed in the table; that gives us all above that to play in.

Band 4	VLF Very Low Frequencies	Below 30 kHz
Band 5	LF Low Frequency	30 to 300 kHz
Band 6	MF Medium Frequency	300 to 3000 kHz
Band 7	HF High Frequency	3 to 30 MHz
Band 8	VHF Very High Frequency	30 to 300 MHz
Band 9	UHF Ultra High Frequency	300 to 3000 MHz
Band 10	SHF Super High Frequency	3 to 30 GHz
Band 11	EHF Extremely High Frequency	30 to 300 GHz

Table 1. Nomenclature of frequencies.

Well, I can hear some of the groans and moans from those who will say, "So what? How in the heck can we get up that high?" I'll tell you: These frequencies are in use commonly by commercial users right up to and well beyond the highest assignment.

The microwave spectrum is made up of bands, referred to popularly by designations such as "S"-band or "X"-band. An examination of Table 3 shows how these bands are designated today. The table was taken from a manufacturer's list of waveguides and waveguide components such as flanges and covers, and, later on, the Electronic Industries Association (EIA) gave additional references. There are many others, but those listed are the most popularly used. Table 3 designations are useful to amateurs who are scrounging the surplus market for components for microwave construction. Many of the components are marked with waveguide designations that may confuse them, however. For example, a waveguide section with an EIA WR designation of 90 will mate with other components that are marked RG-52 and (reading horizontally) can be cross-referenced so that pieces of copper guide or components made of aluminum can be mated.

Similar designations are found on flanges and covers of various dimensions. It is also a guide to square and round flanges which have holes arranged to preclude crossguide couplings.

Many of the older modes of communication are in use on the microwave bands, CW, MCW, and AM, and not too often, pulse-modulated signals are used. SSB has been used, but not without problems that embrace the fundamental stability of the equipment. These problems are being overcome however, and that mode is increasingly in use.

With the advent of the VHF repeater, microwave systems that have been used by amateurs are being pressed into service as control links for receivers and transmitters used to augment coverage of a particular repeater. X-band is being used for many of

160 ... 10 meters	3.5 MHz	High Frequencies only
160 ... 1¾ meters	20.5 MHz	High Frequencies and VHF
420-450 MHz	30 MHz	(20.5 MHz to 10 GHz totals up to 23.290 GHz)
1215-1300 MHz	85 MHz	
2300-2450 MHz	150 MHz	
3300-3500 MHz	200 MHz	
5650-5925 MHz	275 MHz	
10.0-10.5 GHz	500 MHz	
24.0-24.25 GHz	250 MHz	
48-50 GHz	2 GHz	
71-76 GHz	5 GHz	
165-170 GHz	5 GHz	
240-250 GHz	10 GHz	

Table 2.

these systems because of the availability of equipment and because the equipment can be made small. In the repeater system used by The Waltham Amateur Radio Astronomy Society, data is sent between three different sites via radioteletype on X-band, and reprocessed in a Southwest Technical Products 6800-2 computer system. Direct data also has been transmitted to control the WR1AJE repeater operated by the Society.

Present day amateur station equipment has reached a sophistication that makes even the modest frequency-controlling system incorporated in transceivers useful additions to the componentry needed to make up an amateur microwave station.

The frequency relation to the lower frequency equipment is easily mixed up with many of the MW frequencies, or in many cases it simply can be the start of a multiplier chain. An example is operation on the L-band assignment at 1296 MHz. By building a multiplier chain, the output of a low-powered two-meter transmitter can be utilized at 1296 and have the stability of a crystal-controlled or synthesized frequency source. The stability of the overall system, of course, is within the constraints of the frequency error multiplied nine times. But it is stabilized well within the needs of a communication system employing a reasonable receiving bandwidth. Multiplying by 16 of the same two-meter system will put you into 3204 MHz with the same general constraints. Starting with a 432-MHz transmitter will make things easier to construct, but in either case it puts the beginnings of an excellent transmitting system within the realm of any amateur possessing the driving source.

Receiving equipment for these bands can be constructed around lower frequency station equipment and provide excellent companion sections for the method of constructing a transmitter previously described. There are several manufacturers who produce multiplier chains, mixers, and other components made precisely for amateur use at a cost which is within the size of most pocketbooks.

To move up into the higher microwave frequencies one must improvise upon components which are available through the surplus markets, or construct one's own. In many cases the latter approach is easier. Most of the real great steps in microwave communication have been taken by amateurs, and they were using equipment of their own design. In many cases, this departed from classic methods only because componentry was not available. Much has been written about this equipment, and many good DX records and firsts still remain in the realm of amateur radio because of ingenuity prompted by component unavailability.

This same approach must be applied to antennas for microwaves. There are many articles available on the construction of dish antennas if you choose to make one. Several are listed in the references. They can be constructed from plyboard for the ribs and fine mesh for the reflecting surface, and will be as sturdy as your craftsmanship makes them. Some amateurs have made them of aluminum, and these units are certainly as good as the "commercials" make them. They also may be found as surplus or, for that matter, may be purchased as new goods. In any event, it will be important to know the focal

length of these devices for reasons which will become apparent when you design or follow another's design for the "feed" antenna that illuminates the dish. This part of the project is one of the most interesting and will require that you bone up on the subject.

How much gain does the antenna have to have and does a dish have it? Well, I am assuming that you will use a dish, but there are other reflector-type antennas that will work, like the helical, and corner reflectors. They will have gains dependent on how elaborate you make them. These antennas also will work at the microwave frequencies, but with much less efficiency. So, back to the parabolic antenna. As you can see from the plot shown, the gain of a dish is proportional to its size: as the diameter goes up, the gain goes up.

Table 4 was taken from an antenna gain calculator and neglects many factors that this article does not have the space to treat. It does show that from a diameter of 12 inches to six feet, the gain goes up tremendously, and that the reason is that the beamwidth becomes very narrow. The beamwidth scale shows that at 1.3 GHz the angle is 7.5 degrees wide, and that as we move up to X-band, it is only .79 degrees wide at the half-power points for a 96-inch dish. Move the diameter down to 36 inches, and the 1.3-GHz beamwidth is quite wide (nearly 20 degrees) and the X-band beamwidth is 2.7 degrees. You can see that depending on what frequency range you are in, you may either have an antenna that works like a flashlight beam or one that is about like having a multi-element linear array. It also shows that if you choose to make an antenna like a parabolic reflector to be used at the lower frequencies, a dish of 72 inches would be most practical, while at the S- to X-band assignments, a 36-inch reflector will have a power gain of 25.1 decibels at 2.4 GHz, and at X-band, 37 decibels. This is where you make a decision dependent upon the amount of work you must do.

Antenna feeds are another part of the problem and will require great care in construction. They are not very hard to make, however, and most of the work can be done in your shop with hand tools, which makes the rewards even more worth the trouble.

Several manufacturers make excellent equipment for use in amateur bands L and S, which require multipliers to these two assignments. These manufacturers are owned for the most part by radio amateurs who have designed the equipment so that it meets the rigid requirements for the job. The price of the gear is moderate.

Activity in the higher S-band and C-band assignments has been moderate. The S-band frequency is the most used of the two since the equipment available is mostly from wartime radar. The C-band frequency, which is a very interesting one, is quite inactive, probably because of the equipment availability problem. Several interesting reports by amateurs using each of these assignments have appeared in amateur magazines, and should be of interest to those who plan to use them.

Activity in the X-band range (10-10.5 GHz) at the present time is very high. This is because of the availability of much equipment that has been showing up in the surplus area in the past year. Radar-measuring equipment, STL link equipment, and, yes, even police radar sets are showing up as surplus. Several microwave manufacturers make police radar oscillators which easily can be retuned from the police band (10.525 GHz) to the amateur band.

The bands above X-band offer unlimited possibilities. The amount of spectrum available in these frequencies is so large that it becomes hard to compare except to say that considerably more space is available than within all of the other amateur bands combined. ■

Dish Diameter	E-H Plane Beamwidth at 65% Efficiency Frequency (GHz)			Power Gain, dB		
	1.296	2.4	10.2

CB to 10

—part XX: converting the Royce I-655

Shortly before the deadline for the sale of 23-channel CB sets, a local department store ran a special sale to get rid of an overstock of the Royce 23-channel sets. Since the price was so low, I could not resist buying one of the Model I-655s. Although I didn't know exactly what I would do with the thing, I thought the PLL synthesizer was worth at least the purchase price of the unit.

The radio sat in the closet until I saw an ad in *73 Magazine* for conversion kits to put CB sets on 10 meters. Unfortunately, after checking the catalog of kits, I found that none was available for the I-655. The company offered to make a special kit for a $15.00-an-hour engineering fee, but, although this is a reasonable fee, it easily could have cost me more than for the rig itself.

Not easily discouraged, I sent a letter to Royce requesting information on the PLL unit. I received a brief, but polite letter informing me that the unit was sealed and no information was available. Being told this was enough to prompt me to tear into the unit and convert it myself. The project turned out to be extremely easy and straightforward. I will describe now the conversion procedure used on the rig.

It is worth mentioning that the Royce is not the only CB that uses this particular PLL unit. The I-655 is a 23-channel set, but the PLL unit itself is capable of generating 64 ten-kilohertz channels due to the 6-bit binary input that sets the divider chain. I imagine the unit is also used in the newer 40-channel sets as well. By adding only one SPST switch, the extra channels available on a converted 40-channel unit may be obtained on the cheaper 23-channel units.

The block diagram included with my I-655 indicated the rig has three oscillators: 37.38 MHz, 10.24 MHz, and 10.695 MHz. When I opened the unit I found a 36.190 MHz oscillator instead of the indicated 37.38 MHz one. I do not know why the diagram is wrong, but if your unit has the 36.190 MHz crystal, the conversion will work. I cannot say what the results would be on a unit with the oscillator frequency indicated on the block diagram—so be careful.

In order to work on the PLL unit, you must first remove the box that encloses it (I guess this is what is meant by sealed unit). The box is removed by unsoldering the two ends and then snapping it off. Once the cover is removed, you should see a 36.190 MHz crystal roughly in the center of the PC board. Directly below the crystal is an adjustable coil of the metal can type. The two 10-MHz crystals are off to either side. Each oscillator has a trimmer capacitor to touch up the crystal frequency. You will adjust only the coil and trimmer for the 36 MHz crystal, so do not touch the others.

The new crystal frequency is simply 36.190 MHz + the amount you wish to move the transceiver up by. Since I converted my set according to the *73* plan, I moved it exactly 2.0 MHz, giving a new crystal frequency of 38.190 MHz. I ordered my crystal from Jan Crystals, and they were quite helpful in providing the necessary correlation information for me. Table 1 gives the information needed to order a new crystal. Using the 2.0 MHz shift gives coverage from 28.965 MHz (channel 1) to 29.255 MHz (channel 23). If you in-

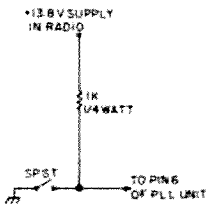

Fig. 1. The switch is closed for normal operation, open for extended frequency operation. (See text.)

Crystal frequency: 38.190 MHz
Type: Third overtone
Holder type: HC-18/U
Equivalent series resistance: < 30 Ω
Load capacitance: 25 pF
Tolerance: 0.0025% or better
Temperature: 25° C (non-oven)

Table 1. Crystal correlation data for the Royce I-655 PLL unit. The indicated crystal frequency moves the output up by 2.0 MHz.

stall the range-extending switch, you will have coverage to 29.575 MHz. The frequencies generated are listed in Table 2 for reference.

Once you obtain the new crystal, solder it in where the original crystal was and connect the rig to a dummy load. When you key the radio, you will have no output. This is because the drive is cut off if the PLL is not locked up. With the rig keyed, carefully adjust the coil directly below the new crystal. At some point the output meter will suddenly jump up, indicating the unit has locked. You will probably need to adjust the coil slightly more in order to get lock over the entire range of available frequencies. My unit would lock over the entire expanded frequency range with no problems.

There are two coils at the end of the PLL board nearest the front of the radio that should be touched up for the best output at midband. In order to set the operating frequency exactly, you will need to couple a counter to the output by an appropriate means, and adjust the trimmer for the 38-MHz oscillator to put you on the right transmit frequency. This also will take care of the receive frequency.

Tuning the *transmitter* and receiver strips are a bit tricky in the I-655, due to the mounting configuration of the PC boards. Since the individual boards are mounted at right angles to the main PC board, you probably will need to make a very short alignment tool to fit the coils. The transmitter board is located next to the PLL unit. There are only three coils to adjust when tuning the transmitter section. These are T401, T402, and L403 on the schematic diagram supplied with the radio. I found that my unit would put about 5 Watts into a 50-Ohm load when properly tuned up. Do not try to adjust L404 since it is fixed (the slug is glued in).

The receiver has only two transformers to adjust in the rf stage. The i-f uses ceramic filters that require no alignment. Using whatever signal source you have, touch up the tuning on T101 and T102. T101 is located at the back of the PC board, above the keying relay. You may want to remove the speaker to adjust T102, since it is partially under the speaker frame. Once you have tuned up the front end, the rig is ready for use. My set checked out with less than 0.3-uV sensitivity for 10 dB (S + N)/N over the entire band.

You might want to add the simple modification to give you the extra channels of a 40-channel rig. As I mentioned before, the PLL unit itself can generate 64 channels. This will cover all the frequencies from 28.965 MHz to 29.605 MHz in 10-kHz steps. Although I did not install the necessary 6 switches to accomplish the full conversion, it is only a simple extension of the single-switch conversion that I will describe. If you install the single switch and use it in conjunction with the channel selector, you will have the 46 channels listed in Table 2. You might want to attach this table to the radio for easy reference.

Turn the radio over and you will see that there are 24 pins which come from the PLL unit and extend through the main PC board. I will refer to these pins as numbers 1 through 24, with number 1 starting at the rear of the radio. Pins 5 through 10 program the frequency of the PLL. On the 23-channel rigs, pin 6 is permanently grounded, disabling the input. To reactivate pin 6, cut the traces on either side of the pin and connect the pin to an SPST switch as shown in Fig. 1. Since you are only switching dc here, you can mount the switch wherever you feel is most convenient. When the switch is closed, the unit operates normally; when the switch is open, the higher 23 frequencies are produced starting with channel 1 on the selector.

If you want to have all 64 channels, simply install six switches in the same manner as given in Fig. 1, one switch for each of pins 5 through 10. With six switches, the channel selector will be nonfunctional and you must program the frequency with the individual switches. It should be an easy matter to make a table of the resultant channels.

I made one final modification that has proven quite useful while operating the rig. I installed a BNC jack on the back of the radio just below the power jack. I coupled the BNC jack to the rf output jack with a gimmick capacitor so that I could monitor the output frequency of the rig.

Although the specific instructions given here are intended for the Royce I-655, they should be broadly applicable to many CB sets which use the same PLL unit. The fact that only a single crystal is needed for the conversion makes the PLL rig a much better value than the heterodyne-type sets requiring several crystals for the same or smaller number of channels. Since the 23-channel PLL sets often can be obtained quite cheaply, this also makes them attractive for conversion when the extra channels can be obtained easily, as I have described. If you opt for the extra channel switch or switches, I would suggest discretion in their use to avoid interference with OSCAR, etc. I will do my best to answer any questions if an SASE is included with your inquiry.■

Something New: the MVM

—"most versatile meter" measures capacitance and frequency

Building the Heathkit function generator was easy—and it worked when I turned it on. I soon realized, however, that if I wanted to know the output frequency more accurately, I would have to have a separate instrument that would give me a quick and easy-to-read value. I could, of course, have built a digital counter, a harmonic crystal oscillator, or any of a number of exotic frequency-measuring devices, but all I wanted was a simple device that would be easy to build, simple to calibrate, and easy to read. Little did I realize what I was about to find out!

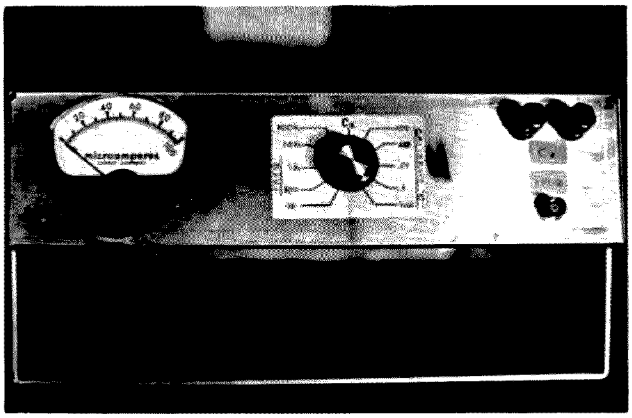
Some years ago, when atomic physicists required a device that would measure pulse rates from radioactive materials, they came up with the simple circuit shown in Fig. 1.

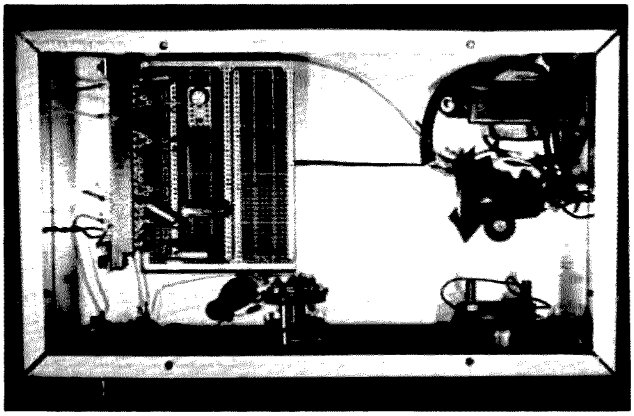
Before we get into the operation of this device, however, it is necessary to know that the pulse input to the circuit must be shaped. This is called "signal processing." The pulse required must have a fast rise and fall time and also a specific duration time. What I'm describing is a pulse like the one in Fig. 2(a), where t_r is the rise time, t_f is the fall time, and t_d is the pulse duration. If t_r and t_f are very short, then the pulse will look rectangular, as in Fig. 2(b). This is the kind of input signal needed by the circuit in Fig. 1.

Keep in mind that the input signal—the frequency of which we want to measure—can be a sine wave, triangular wave, square wave, or something in between these shapes. To turn these wave shapes into rectangular pulses, we need a trigger circuit, a squaring amplifier, or a zero-crossing comparator.

The RCA 3130S, a fairly new operational amplifier with differential input, was selected as a zero-crossing comparator. This device has an excellent frequency response which allows a rapid output voltage rise as the input voltage crosses the zero or reference point. This is true even if the input voltage is rising very slowly, because, as the input voltage crosses the reference point, the gain of the amplifier snaps the output voltage toward saturation, which is approximately the dc supply voltage—in this case, 12 volts.

The RCA "Solid-State Devices Manual SC-16" states that small amounts of positive feedback and symmetrical supply voltages would allow the device to operate satisfactorily to over 1 MHz. The maximum frequency we are interested in, however, is only 100 kHz. To preserve circuit simplicity, I decided to stay with the single supply voltage and no frequency compensation or bias control. This can be seen in the complete circuit diagram of Fig. 3. Note that a low-impedance driver circuit was added to ensure that the pulse shape would not





be degraded by the meter circuit.

Meter Circuit

Now refer to Fig. 4. Many people, when writing about this circuit, describe it as a rectifier and let it go at that. It is a rectifier, but without the input capacitor and the pulse-type waveform of input, we will learn that this circuit would not be so useful.

If you ask how much electric charge moves into the capacitor when a particular constant voltage is applied, you will find that the following relation holds: Q = VC, where Q is the amount of charge that has moved into the capacitor, C is the capacitance in farads, and V is the applied constant voltage. I keep using the words "constant voltage" because I want to be sure that the charge reaches a specific value and does not change.

Remember, too, that a capacitor does not charge instantly but takes an amount of time that depends on the resistance in series with it. The mathematical shorthand t = RC is used to describe the phenomenon, with t the time in seconds, R the resistance in Ohms, and C again being in farads.

The graph in Fig. 5 shows the amount of time represented by RC. If we multiply the equation by ten, however, we come very close to the time it takes for the capacitor to reach full charge. So, let t = 10RC, where t is now the time it takes the total charge (Q) to move into the capacitor through the resistor (R).

Now we can get back to our measuring circuit. We have just learned that in order for the charge to reach a constant value, the time that the voltage is constant must be greater than 10RC. To ensure this, all we have to do is make the duration of the input pulse, t_d, greater than 10RC. This is written: $t_d > 10RC$.

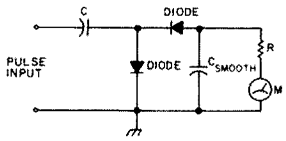


Fig. 1.

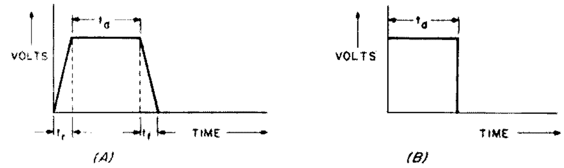

Fig. 2.

Look at Fig. 4. Assume that the pulse is at +V, S1 is closed, and S2 is open. C is, therefore, charging through R and the meter. Now assume that the pulse has passed and the input is at 0 volts. This is the same as saying that we have a wire connected from the capacitor to the ground wire. At this time, we also open S1 and close S2. This completes the discharge circuit, and C discharges very rapidly because the discharge resistance is usually very small. Now if we bring the next pulse along, close S1, and open S2, another charge cycle occurs—and so on.

Also, notice that more charge will move through the meter if the input pulse rate or frequency is increased. This charging current always moves through the meter in the same direction, so the meter reads a pulsating dc value. This is why it is referred to as a rectifier, or, in the mathematical sense, an integrator.

Now that we know how the circuit works, we have to answer only two major questions. First, what can we use for the switches, and second, how can the circuit be used for measurement purposes?

The switching can be handled by mechanical relays or semiconductor FETs. Both of these devices require some kind of circuitry synchronized with the incoming pulses. The simplest switches, however, are diodes. The potentials (voltages) occurring in the circuit cause the diodes to switch automatically to the proper position. With no need for synchronizing circuitry, let's use diodes.

The second question, how to use the circuit for measurement purposes, is best answered by some simple arithmetic. Remember that the capacitor is fully charged during each pulse if the voltage reaches a value, V, and remains constant for a time, t_d. If we multiply the charge by the frequency, (or by the number of pulses per second), we get: FQ = FCV, where F is the frequency.

If we realize that FQ is equal to the total charge that flows each second and we remember that "charge per second" is the way current is defined, it is easy to see that we can rewrite our equation as: I = FCV, where I is the current in Amperes—and there you have it!

What this equation says is that if V (the pulse height) and C (the input capacitor) are kept constant, we can use this circuit to measure frequency, F. If, on the other hand, F and V are held constant, we can

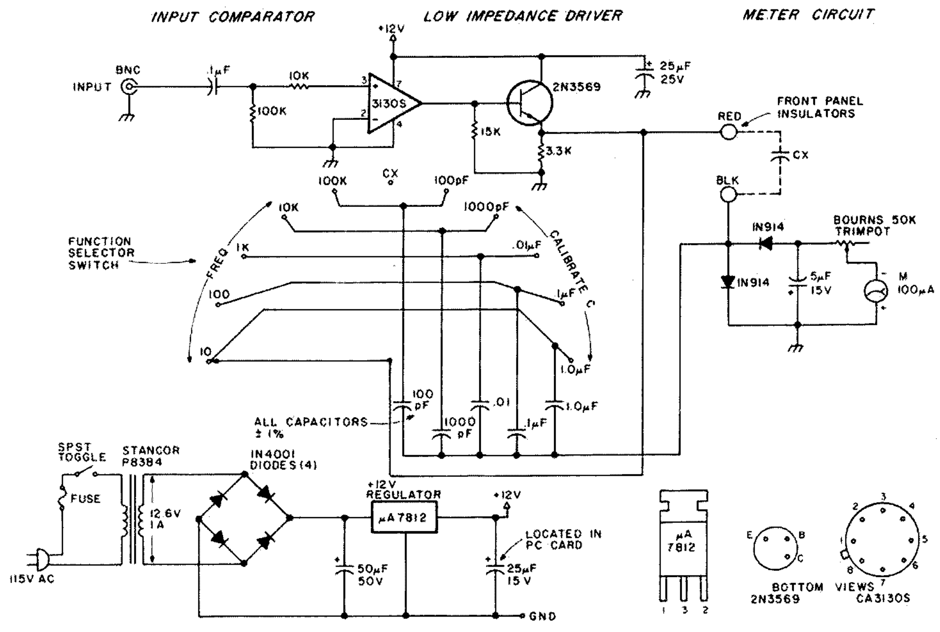

Fig. 3.

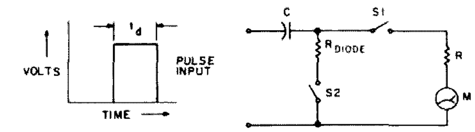

Fig. 4.

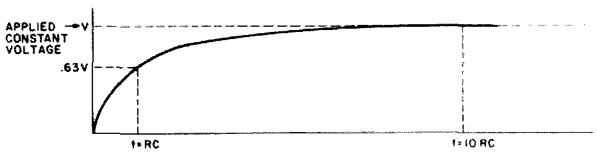

Fig. 5.

measure capacitance, C.

As an example, if we let the pulse height (V) = 10 volts, F = 100 kHz, and C = 100 pF, then I = 100 × 10^{-12} × 10 × 10^5 = 100 × 10^{-6} = 100 microamps. With a capacitor of 100 pF and a 100-microamp meter, we now can measure any frequency from 0 to 100 kHz.

One interesting twist to the circuit (see Fig. 6) is that if we multiply the average current (I) by the resistance (R), we get (from Ohm's Law) a voltage, e. Our equation now becomes: IR = e = RFCV.

If we measure the voltage across the resistor with a high input impedance voltmeter, we now can measure not only F and C, but also R or V, the pulse height.

One last point: Since the metered values I and e are linearly related to the values we are measuring — R or C or F or V — calibration is very simple. It is necessary to calibrate at one point only.

The instrument I've finally ended up with can measure both capacity and frequency when used with the Heathkit function generator.

Construction

The photos give an indication of how this instrument was assembled. Most of the electronics were mounted on a 4½" by 4½" printed circuit card. The power supply and regulator components are mounted on a "cut to fit the chassis" perfboard, seen just above the transformer. The power-on switch, meter, function-selector switch (frequency or capacity), input BNC connector, and "unknown capacitor" (C_X) terminals are all on the front panel. The PC card is plugged into a 22-pin edge connector that is mounted on two metal brackets. Everything is enclosed in an aluminum 3" × 12" × 7" chassis with a bottom plate. Incidentally, a PC card that I find very useful is the Vero DIP board no. 06-0147B. It handles integrated circuits as well as discrete components and can be clipped to fit tight quarters with a hacksaw or, better yet, a jeweler's saw.

Operation

Switch the instrument on and set the function selector switch to 100 on the frequency side of the switch. Connect a 50-to-100-picofarad capacitor (ceramic or mica) to the hot side of a 115 V ac line, and connect the other side of the capacitor to the center lead of the BNC connector. Connect a .1-microfarad capacitor (paper or ceramic) from the ground side of the 115 V ac line to the chassis or ground side of the BNC connector. Adjust the 10-turn pot in series with the meter so that the meter reads 60 Hz. These capacitors are necessary to reduce the 115 volts to a level that will not burn out the input circuit. (They are not necessary if you use the output of a 6-volt filament transformer.)

The instrument is now calibrated. You can use any frequency that you are sure is accurate on any of the ranges from 10 Hz to 100 kHz to do this calibration. Notice that the frequency side of the function-selector switch is connected to the "capacitor calibrate" side of this same switch. This puts the proper capacitor in series with the measuring circuit. In order to be sure that this accuracy is maintained in the frequency measurement, these capacitors should have a tolerance of not more than ±1.0%. Since these capacitors are available, we can use them to calibrate the instrument to measure capacity.

For example, suppose we want to measure capacity between 0 and 100 pF. Set the function selector switch to 100 pF on the capacitor-calibrate side of the switch. Connect the input BNC connector to an audio generator, or to your Heathkit function generator, and set the generator to 100 kHz (the frequency value on the frequency side of the switch). Increase or decrease this frequency so that the meter reads full scale. Now flip the function selector switch to the C_X position. The capacity meter is now ready to measure values of capacitance between 0 and 100 picofarads. The same procedure is used on the other ranges. ■

Amplify Your 6-Meter Fun

—a cheap but effective linear

After I managed to scare up enough cash for a new FT-620B, I was amazed at the good results that I was obtaining with a puny 14 Watts output. After a few modifications (S-meter circuit, alc, etc.) and super-tweaking, I was able to cough up 17 Watts —not bad. Even then, the FT-620B was not able by itself to work the long-haul ground wave which I was accustomed to with my previous 6 meter SSB rig.

I decided that it was time to construct an afterburner for the 620. Next came the problem of what to use for parts and tubes. In northeast Georgia, electronic parts are as scarce as hen's teeth; so it must be simple. So, now I had 17 Watts of drive available—too much for a 4X250B tube and too little for a 3-500Z. Then I remembered our old friend the 811A (or 812A, even). According to the specs, it's good for 170 Watts output to 60 MHz with 12 Watts drive and 1400 volts on the plate. People laughed when they heard me on the air discussing an old 811 on 6 meters. Now everyone in the local area is building one, especially when 811As can be obtained at our not-so-local parts store for 3 bucks a throw, including 4-pin socket!

Construction

I built the amplifier on a chassis and cabinet which once used to be a WRL 6 & 2 MTR Hi-Bander transmitter. I was able to use the same power transformer, meter, switches, and the 2 coax SO-239 connectors for antenna and transceiver. However, after construction, I realized that the whole amplifier could have been built on a smaller 7" x 9" x 3" chassis with front plate, back plate, and top covers.

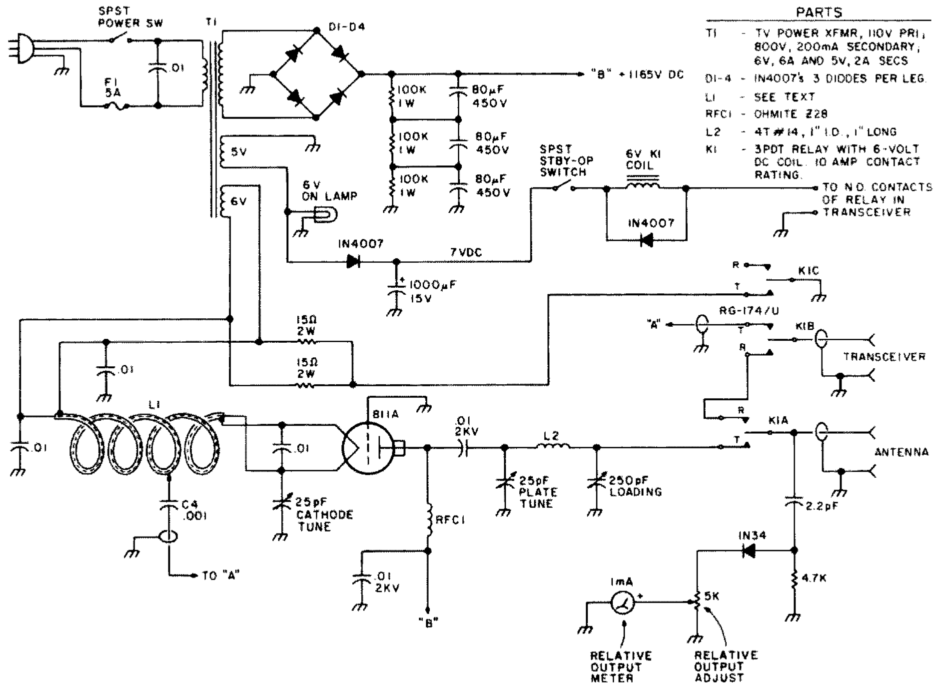

Fig. 1. 6 meter linear amplifier.

As the schematic shows (Fig. 1), T1 is a TV power transformer, with an 800-volt secondary at 200 mA, 6 volts at 6 A, and 5 volts at 2 A. A transformer with voltage higher than 800 volts can be used, maybe to 900 volts ac maximum. A rating lower than 800 volts ac will not give enough plate voltage. My transformer yielded 1165 volts with no load and 1080 volts under load, measured at the top of the filter capacitor bank. The ac line cord is a 3-prong unit, with the ground pin going to chassis ground. The rectifier bank, D1-D4, is made of 4007s with three diodes in each leg. Relay K1 is a 3PDT P & B relay with a 6-volt dc coil and 10-Amp contacts. One pole of the relay grounds the cathode circuit during transmit and the other two poles control

the antenna circuits. The standby/operate switch applies 7 volts dc to the relay coil in the operate position; the other side of the coil gets grounded by the normally-open relay accessory part of the transceiver during transmit. It should be noted that plate voltage appears on the 811A at all times, but it draws no plate current unless relay K1 is energized. I have found that smaller relays do not like 1165 volts on their contacts, so interrupting the cathode circuit between was a logical move since there is only a small amount of voltage in the cathode circuit.

The 25-pF cathode tuning capacitor can be any small air variable or ceramic trimmer. The 25-pF plate capacitor is a small double-spaced air variable and the 250-pF loading capacitor is a modified 365-pF variable salvaged from an old bc-band table radio. The plate tank circuit was built with short leads as close as possible around the 811A. I had my 811A countersunk in the chassis to facilitate shorter leads in the tank circuit.

The relative-output meter circuit is simple and adjustable. I have it wired so that it can measure transceiver output or amplifier output, depending on whether the amplifier is on or off.

Coil L1 is the heart of the whole amplifier. It consists of 4 turns of 1/8" copper tubing wound to produce a coil 1½" long and with a ¾" i.d. However, before the tubing is bent into a coil, insert a piece of #18 teflon™-covered wire. Now we have a 2-conductor coil. Attach the coil to the 4-pin tube socket on one end. The other end should go to a terminal strip mounted on the chassis. Mount the two .01-uF filament capacitors and two 15-Ohm resistors on the terminal strip.

Tack-solder the .001-uF cathode coupling capacitor (C4) approximately 1 turn from the filament end of the copper coil. The rest of the construction should be simple and straightforward.

Testing and Use

After construction, carefully check for shorts and cold solder joints. Check for a short in coil L1. If you used teflon™ inner conductor, you should have no problems. Rubber or vinyl wire used for L1 will melt when soldering the copper tubing. Fire up the amplifier and check for HV and filament power. Temporarily break the HV line and insert a milliamp meter. Energize relay K1 and check the idling plate current. It should be about 20 mA. Now apply a small amount of drive and peak the cathode tuning for maximum plate current and tune the tank circuit for maximum output. Now, note the drive power and experiment with the location of the C4 capacitor tap on L1. Adjust the tap placement and cathode tuning capacitor for maximum efficiency. There will be a certain tap placement of C4 which couples the most drive power to the filament/cathode circuit.

With about 14 Watts of drive and the tank circuit fairly loaded, the plate current will be about 175 mA with 1100 volts on the plate. This produces 120 Watts dc output. Your amplifier should now be ready for service. I built my amplifier for a grand total of about $25, including scrounged and begged parts. Besides using an 811, I also plugged in an 812A with similar good results. ■

CB to 10

—part XXI: the Johnson Viking 352

Here it comes folks, another CB rig converted to ten meters—the Johnson Viking 352. This rig has a great deal of flexibility when properly modified. It can offer more features than the average CB-to-ten-meter conversion, and this means more QRP contacts for you.

The 352 is an SSB/AM eleven-meter 23-channel transceiver. The logical place to convert it seems to be 28.5 MHz to 28.8 MHz, so the SSB can be used at the lower end and the AM section will cover the upper end where there is activity in this mode.

At this point, it would be wise to pick up the Sams Photofact® no. CB-112 on the rig if you don't have the schematic for it already.

The rig has a standard four-by-six crystals synthesis scheme, so the bank of four crystals is changed in the interest of economy. The bank of crystals was changed from the 7 MHz range to 9.065 MHz, 9.045 MHz, 9.035 MHz, and 9.025 MHz for crystal positions Y610 to Y607 respectively. While awaiting delivery of your crystals, you can perform the following modifications to attain greater frequency coverage (fill in the "holes" between channels) and add one more channel.

First, we will activate the mysterious "blank" channel between channels 22 and 23. Locate the pink wire which runs from S1, deck C, pin 14 to R608 and disconnect it from the switch deck. Tape the end so that it will not short to anything else, and *voila*, 24 channels.

Next, we switch the fine tune from a receive-only function to a receive-and-transmit function. Cut the green wire at relay K1's swing arm and reconnect it to the fine-tune potentiometer (R625) wiper. This produces approximately 2 kHz of transmit-and-receive fine tune which is usually not enough for serious QRP work on ten meters. The fine tune can be expanded to 10 kHz and more by adding a variable inductor (Miller 4204) between the anode of CR606 and ground. Note that this is a variable inductor; a frequency counter should be used to adjust it to allow a maximum of 12½ kHz of fine tune. Any more than this will cause excessive non-linearity and fast tuning in the fine-tune knob.

When these modifications are complete and operating well, your new crystals should be well along the way. When you get them replace Y607 through Y610 with 9.025, 9.035, 9.045, and 9.065 MHz, respectively. Connect a frequency counter to TP1; with the Johnson Viking 352 on channel 11 AM, adjust T601, T602, and T603 for an output of 20.845 MHz. Be sure that 17 or 24 MHz are not present, or the synthesis won't come out right. This part can be done with an oscilloscope, using a hand calculator to determine freculator to determine frequency. (This is how I do it.) After you have the 20.845 MHz, adjust T601, T602, and T603 for maximum rms voltage at TP1. Now change the controls to channel 13 and USB; with the VTVM rf probe or scope still connected to TP1, adjust T604, T605, T606, T501, and T502 for maximum.

The synthesis is now producing 28 MHz rf and the receiver needs to be aligned. Set up a low-level signal source at approximately 28.6 MHz. If you have obtained and installed the previously-mentioned crystals, 28.6 MHz should be at channel 7 with the fine tune at 9 o'clock position. Couple the weak signal source to the antenna jack and adjust T401 through T409 for maximum signal indication on the S-meter. (Be sure to reduce signal strength as you align the receiver, to avoid overload and false tuning.) The transmitter alignment is done by using an output indicator and a 52-Ohm dummy load which is capable of handling 5 Watts or so. Adjust T701 through T705 for maximum output power.

Now, that was easy, wasn't it? Whatever your answer, you now have a rig which will perform very well and provide the flexibility to work QRP on ten meters. I have converted four of these rigs, and all of the operators (including myself) are doing very well with modest antenna systems. I am presently 8 states away from my WAS QRP 10m SSB, have worked all continents, and have 48 countries worked (including a JT1, a 5N2, and a VP2S). Not bad for an obsolete CB rig. See you on ten meters QRP.■

Exploring Uncle Sam's Bookstore

—what's for you at the GPO

"Oh yes," I kept telling myself. "One day I'll find the time to study so I might earn my amateur radio license." That was my total commitment for a period of at least twenty years, until about one year and a half ago. At that point, I decided to devote the necessary time to some honest study toward that end.

My first task was to locate reference materials in order to accumulate the information that would aid in preparing for the written examinations. Although I am employed at what some consider to be the world's largest printing establishment, the US Government Printing Office (GPO), I did not realize initially that the GPO bookstore would be a ready source and a prime repository for such specialized literature. This discovery was made one day when I walked in to purchase a current copy of the FCC Part 97, Amateur Radio Service Regulations.

There, to my amazement, on the bookshelf beside Part 97, were many publications relating to the general categories of communications and electronics. Some further investigating on my part revealed a number of relevant publications that are both informational and useful to the radio amateur. The wide range of topics and titles

available were extremely helpful to me, and can serve your needs also, if you are in search of additional study or reference books to place in your home or club library.

As a convenience to the reader, I present an abstracted listing of US Government publications of general interest to radio amateurs. Shown in the listing are the document title, publication date, number of pages, GPO stock number (necessary for ordering), and current selling price. (Prices and availability are subject to change.) Also shown is a listing of 20 GPO bookstores located in major US cities. You may wish to contact your local GPO bookstore for ordering or if you desire you may place your order with the Superintendent of Documents, Washington DC 20402. Prices shown are for domestic mailing. Add 25% for orders mailed outside the US and its possessions. Any specific questions you may have should not be directed to me but to the Superintendent of Documents.

I'm sure that you will find, as I did, many helpful and interesting publications here for both beginners and experienced radio amateurs.■

San Jose CA 95124

Computerized Slow Scan . . . Revisited

—further enhancements for the K6AEP system

SSTV is probably one of the most exciting means of amateur radio communications.

In what other mode of amateur communications can you see the person you are talking to even though the amateur may be thousands of miles away?

Interest in SSTV is growing daily, and one of the easiest ways to experiment with it is by using a microprocessor. Never before have amateurs been provided with such a flexible, powerful tool. The microprocessor provides a means of changing its function by loading into its memory a series of instructions called a program, or software.

This article was written to upgrade the software package described in my previous article.[1] It will explore the effect of digitizing SSTV pictures with more picture elements (pixels) and gray levels. It also will tell how to rotate pictures and title pictures in computer memory. For those of you who are not aware of my previous article, I think a short review might be appropriate.

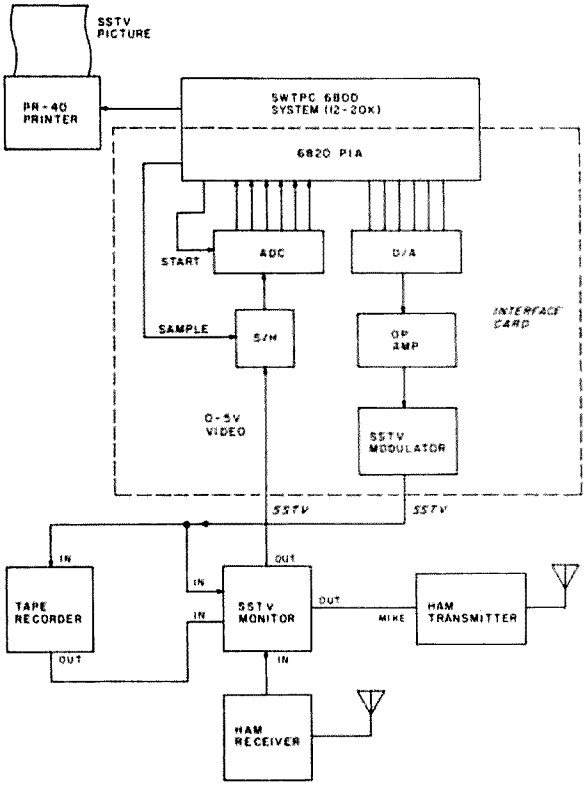

Fig. 1. Computer interface.

The SSTV Enhancement Program

In my article, I provided an interface between an SSTV monitor, a ham transmitter, and an SWTPC 6800 computer system. Fig. 1 provides a block diagram of the interface card. The interface card accepts sync pulses and video which have been previously demodulated and scaled to a 0- to 5-volt swing from the SSTV monitor. The video input portion of the card consists of an analog-to-digital converter (ADC) and a sample-and-hold (S/H). The computer output consists of a digital-to-analog (D/A) converter, an amplifier, and a SSTV modulator. All of the analog devices are connected to a 6820 PIA which allows the computer control.

The software package in the article made it possible to (1) receive and transmit SSTV from the SWTPC 6800; (2) print hard-copy SSTV pictures on an SWTPC PR-40 printer; and (3) enhance the picture in computer memory, since it would remove noise by averaging pictures received, add contrast to pictures, zoom in on 5 areas of the picture in memory by 2 times, reduce the gray level content of pictures on transmit from 16 to 2, and produce negative or inverted pictures. All of these pictures were digitized to 128 pixels on 128 lines with 16 gray levels.

Picture Quality

When I determined the picture density for my original article, the above seemed like a good idea at the time for two reasons. First, only 12K of memory was required for the SSTV picture and control program; second, the Robot 400[2] used this format with the same number of picture elements and gray levels as I planned.

During the initial stages of the project, I discussed my idea with knowledgeable people. They warned me that more picture elements would produce better results. Despite these warnings I proceeded, and, sure enough, they were right. My results were

Photo 1. Analog SSTV picture.

Photo 2. SSTV picture digitized to 128 pixels with 16 gray levels.

marginal.

After a little prodding by others. I decided to perform a few experiments to determine the effect on picture quality of changing the picture elements per line and gray level.

Since the control of the SSTV picture reception is accomplished by constants in the software, the experiment was easy to conduct. I decided to increase the pixels per line in gradual steps to see the effect. I had a few concerns relative to computer overhead, since all of my routines were fine-tuned for 128 pixels per line. If I tried to digitize the picture with too many pixels, the memory requirements would be high. Additionally, I would reach a point where the software would not function due to execution speeds. I decided that the maximum memory requirements for the picture would be 16K. With this requirement in mind, I decided to experiment by (1) varying the pixels/line from 128 to 176, 224, and 256, and (2) keeping the format at 128 pixels by 128 lines and increasing the gray level content of the picture to 64.

The pixel variation experiment took only a few hours to perform. It was quite easy, since only 7 memory locations had to be altered in the enhancement program. I found that the 256 pixel/line rate was the maximum rate which my systems would support. If I had had a faster clock, a higher picture density could have been achieved.

The gray level variation experiment took a little longer. It involved the writing of an entire routine, which ended up with about 256 bytes of object code. No hardware changes were required, since I planned ahead on my initial design of the interface card and placed six bits of the ADC and D/A on the PIA (6820). The results were interesting. Photos 1 through 4 show my results:

Photo 1. Normal SSTV Picture. This picture was produced by a TV camera and a scan converter. The SSTV picture was displayed on an MXV 100 (P7 CRT) monitor.[3]

Photo 2. Digitized Picture (128 pixels). This picture was digitized to 128 pixels/line on 128 lines with 16 gray levels. The picture has some 60-Hz ripple in the monitor/computer interface, due to a ground loop which I have not found. The picture also contains some software jitter which I will discuss later.

Photo 3. Digitized Picture (256 pixels). This picture was digitized with 256 pixels/line on 128 lines with 16 gray levels.

Photo 4. Digitized Picture (64 gray levels). This picture was digitized with 128 pixels/line on 128 lines with 64 gray levels.

After close scrutiny of the pictures and analyzing the results on my monitor, these conclusions were drawn:

1. The picture density of 128 pixels on 128 lines, with 16 gray levels, produced marginal results. If the 60-Hz noise and jitter were removed, the results would be somewhat better.

2. A density of 128 pixels on 128 lines, with 64 gray levels, produced better results. However, the problem of contouring would appear if a zoom feature were added.

3. The best all-around digitized picture tested had 256 pixels on 128 lines, with 16 gray levels.

This selection was not based entirely on picture quality, but also on memory size and the amount of contouring experienced. The contouring could be reduced even further by averaging pixels together before they were transmitted. I did not try to program this feature, since my system overhead was so

Photo 3. SSTV picture digitized to 256 pixels with 16 gray levels.

Photo 4. SSTV picture digitized to 128 pixels with 64 gray levels.

high that it might not have been possible with the standard SWTPC cycle-time of approximately 1 MHz. A faster CPU card would have been desirable in this application.

The implementation of the 256 pixels/line feature required numerous changes in my enhancement program software package. I decided to use code, which modified the basic program for the selection of either 128 or 256 pixels/line. The effect of higher picture densities thus can be observed quickly by the selection of program options. The process of modifying all of the enhancement algorithms for the additional density was complex. I found that everything but the noise routine could be modified for the higher density. This routine has high overhead even at 128 pixels per line.

I decided to include the software in this article for the 128 pixels on 128 lines, with 64 gray levels, as an optional program. The program was assembled on a boundary greater than 20K and allows for further experimentation.

Additional Features

For some time I have felt a need existed to add titles to SSTV pictures received. Since all the SSTV inputs are routed through the SSTV monitor, the software now allows titling of pictures received over the air, outputted from a tape recorder, or generated by a scan converter. The applications of this feature are endless.

I decided to make the letters small and allow a total of 9 lines to be displayed with 9 characters on each line. This size was found to be very adequate and visible under QRM conditions. I additionally decided to add the letters with and without background and to select the lettering with and without gray level. I assembled into my program only the selection of white or black characters, but a gray level selection can be made by changing program constants.

The titling feature is available for only 256 pixels/line for two reasons. I felt that the character resolution would not be sufficient with 128 pixels/line, and I did not have enough memory available in the remaining lower 4K to support the luxury of switching between 128- and 256-pixels-per-line lettering. Photo 5 is an example of the various modes of titling.

Another feature added to the package was the ability to rotate pictures on transmit. The overall effect has been dramatic and demonstrates the power of microprocessors. Imagine receiving an SSTV picture over the air, adding titling to the picture, and then sending it back to the originator rotated at either 90° or 180°. With more memory available, it would be fun to code the routine to rotate the picture by any 45° angle between 45° and 315°. I'll leave this exercise for some future date.

Software Concepts

To understand the software, it is important to first know how an SSTV picture is formatted in computer memory. Fig. 2 depicts a typical SSTV picture in memory, formatted to 128 or 256 pixels on 128 lines, with 16 gray levels.

As you can see from Fig. 2, two pixels are packed into one byte. This allows the picture to be stored efficiently into memory, since all bits in each byte contain picture information. However, this software format was considerably more difficult to write, since bytes must be separated or packed into nibbles (4 bits) prior to each operation. Part of the

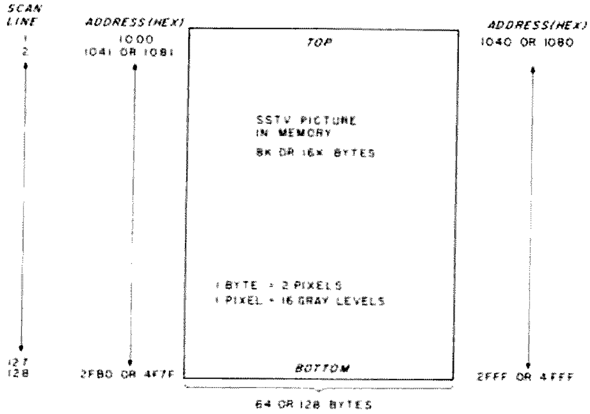

Fig. 2. Digitized SSTV picture memory map.

so-called 60-Hz noise shown in the preceding pictures is due to the unpacking of the nibbles on transmission to the SSTV modulator on the interface card. This noise, or jitter, is due to unequal cycle times in the software which was used to unpack each nibble. If I had been aware of this problem during my initial coding of the program, I would have eliminated this condition.

The 64 gray level pictures were formatted in a different manner. Since six bits were available on the ADC and the D/A, I decided to pack all bits into a single byte. This process made the coding of the software much easier. A side benefit was that I took more care in my software to eliminate jitter, and the results show an improvement in this regard. The 64 gray level picture requires 16K of memory and does not use 2 bits of each byte to store picture information. One bit is not used and the other is used for sync.

The Software

Fig. 3 contains a complete source listing of the program. Fig. 4 contains a listing of the dot and translate tables for the character dots. I'll discuss the software by function, and describe each routine used or called for by the main line program.

Pixel Selection

The pixel selection of 128 or 256 pixels was made by modifying the code of the SSTV enhancement program.[1] Five routines were modified in the enhancement program: receive SSTV, xmit SSTV, zoom, contrast enhancement, and print. The modifications consisted of two types: address changes and constant changes. The address changes were used to tell the software where parts of the picture are located in memory. The constants were used to tell the software how many pixels are contained in each line of the SSTV picture, and also for delay constants.

I will not go into detail on how these constants were selected, but two points are important. The noise routine of the enhancement program will not function at 256 pixels/line due to program overhead, and the 256 pixels per line is the maximum rate at which the software will function. This is due to a combination of software overhead and ADC conversion time.

Picture Rotation

The picture rotation was divided into two types—180° (upside down) and 90°. I'll discuss the simplest one first, the 180° rotation.

Photo 5. SSTV picture with computer titling.

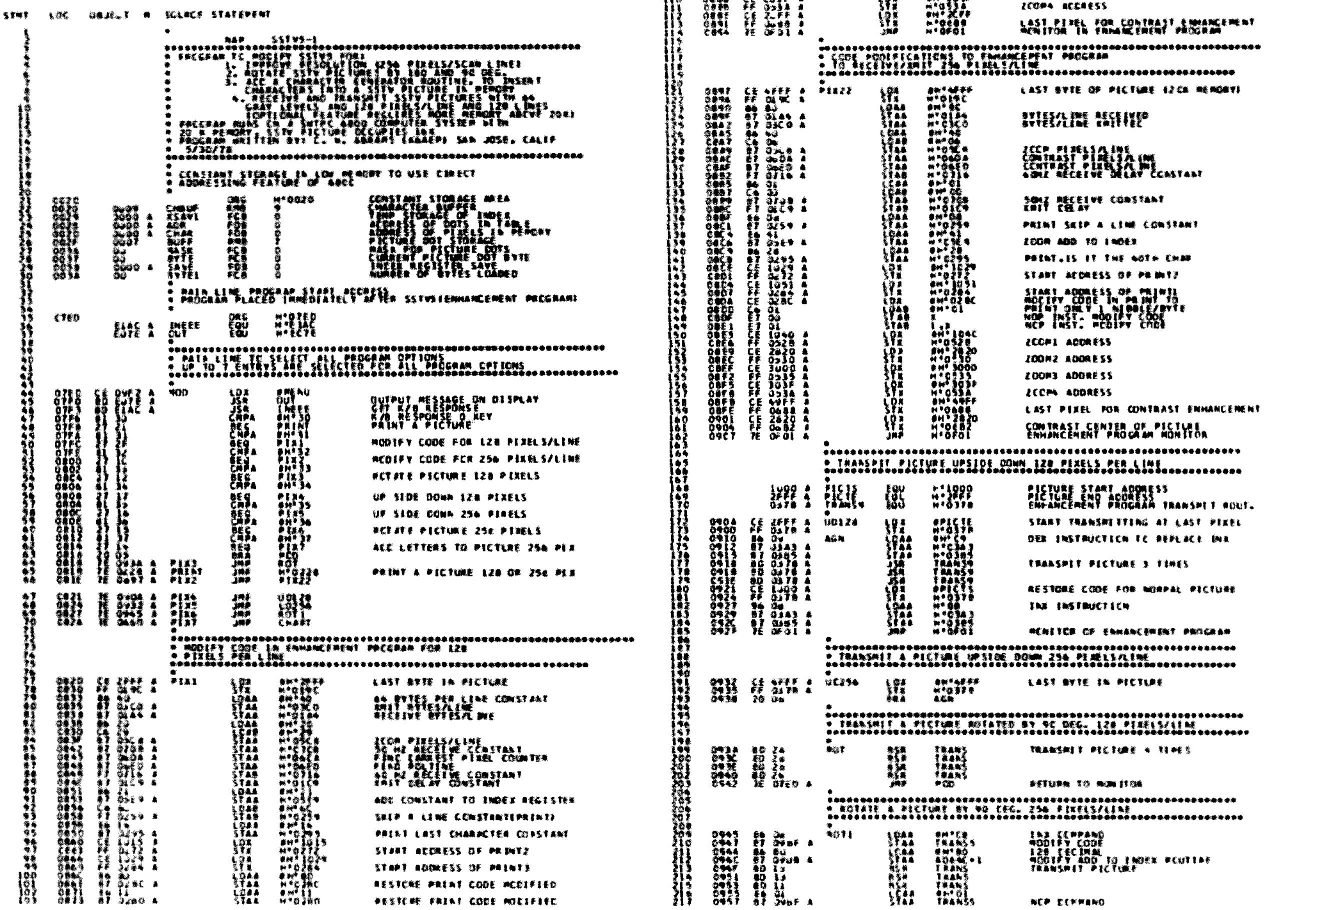
Two routines are used to accomplish this, UD128 and UD256. The number in the label refers to the picture density. These routines modify two instructions in the transmit routine of the enhancement program for an INX (increment index register) to a DEX (decrement index). The transmit routine in normal operation is entered with the first byte of the picture start address. Each byte then is transmitted, and the index is incremented until the last byte is transmitted. To transmit a picture upside-down, all that has to be done is to load the index with the last byte of the picture and decrement the index register. This trick was easy and took only 50 bytes of code.

The 90-degree rotation took a little more code. The main line routine is ROT and ROT1. A flowchart was not provided for this routine, since all lines of code are well commented. I took care in this routine to remove all software jitter. This was accomplished by transmitting each nibble of the byte in the same number of CPU cycles. At address 0972-5, four NOP instructions were assembled. These instructions compensate for the four ASLA instructions at address 099A-D which are required to format the byte for the transmission of the 2nd pixel.

The operation of the routine is quite simple. All that has to be done is to load the index with the start address of the picture, transmit the high-order nibble, and then add 64 or 128 to the index register. The index is now pointing at the first byte on the next line. If you repeat this process for all bytes and nibbles, the SSTV picture will be transmitted at 90 degrees.

After writing this routine, I found that I scanned the picture backwards. Wow! What the software produced was a mirror-image

Fig. 3. Program source code.



of the picture at 90 degrees. After much thought, I decided not to rewrite the routine. The effect was very dramatic and has caused some interesting discussions over the air. The solution requires a few patches to the program and the writing of a routine to subtract 64 or 128 from the index register. Since my memory requirements were tight and it might be tricky to implement a change, I left the routine alone.

Fig. 4. Dot and translate table.

Picture Titling

This routine was the most complex portion of the program to write. I considered future expansion in the writing of the character generator routines. What I needed was a general-purpose character generator which could be modified for any dot matrix size or gray level. I started by using the concepts described in my June, 1977, article.[4] The problem, however, was a little more complex, since the characters are inserted in a 16K block of memory. I decided that the characters should be quite small and consist of the following format:

Character Dot = 2 bytes (horizontal) or 4 pixels.

Character Dot = 2 scan lines (vertical).

The next job was to program the beast. I decided to use the dot and translate table contained in my October, 1977, article.[5] I relocated this table to address 0D00 and 0E00 to reside within the lower 4K of memory. Since I was running out of available memory, I decided to use the lower 256 bytes of memory which use the direct addressing mode of the 6800. You can save a lot of memory by this technique, since many instructions require only two bytes to address this portion of memory.

To give you a blow-by-blow account of how the

program works would be very complex and take many pages. As you can see from the source code, I have included many comments on each subroutine and on how they function. I suggest that if you wish to convert my code to another processor, you should study the code very carefully. A brief description of each routine follows:

1. *CHART*: This is the main line routine for the selection of all titling. The routine prompts the operator by asking questions. All responses are either numbers, y for yes, or n for no. If you wish to experiment with gray level lettering, the byte at OAE7 can be changed from FF (white) to another gray level. Photo 6 is an example of the routines menu-displayed on the TV monitor.

2. *CHAR10*: This is a jump table which tells the program where, in the 16K picture region, the lines of titling are to be inserted.

3. This routine is the main line for the entry of picture dots into the SSTV picture in computer memory. The 9 characters to be entered are stored in ASCII in a small buffer *(CHBUF)* at address 20. The routine loops nine times to enter each character's dots into the picture.

4. *FSLA*: This is the first routine called by *ENTER*. The routine is entered with an ASCII character in the A accumulator and exits with the address of its picture dots in ADR. The routine uses self-modifying code to add the offset of the translate table to the index register, to find the character dot's address.

5. *FILL*: The next routine called by *ENTER* is *FILL*. This routine takes the seven bytes of the character 5 x 7 dot matrix and places it into a 7-character buffer *(BUFF)* located at address 2F.

6. *LOAD*: This routine is the most complex of the character generator routines and calls for two other subroutines. *LOAD* increments through *BUFF* one byte at a time, calling *PLACE* and *DOTX*. *PLACE* ANDs a mask over the byte, which contains the character dots of one character scan line. After ANDing the mask, *DOTX* is called and a test is made

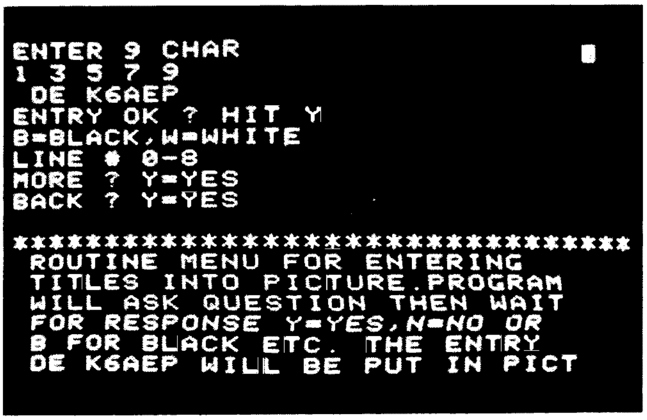

Photo 6. TV menu for titling routine.

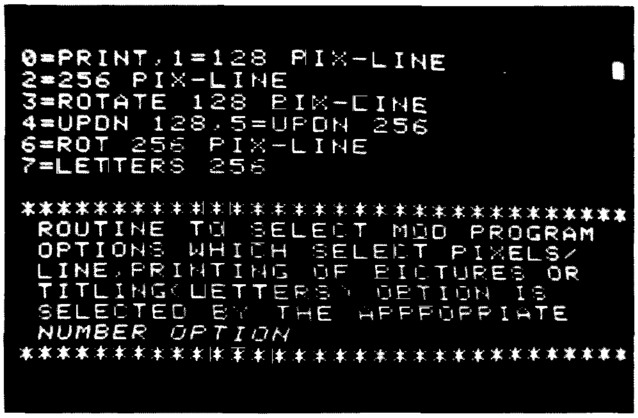

Photo 7. TV menu for program option selection.

for zero. If the results are zero, a return from subroutine is executed. If the results are not zero, the gray level byte *DOTG* is loaded in the A accumulator and stored indexed at 4 locations (X, X+1, X+128, and X+129). This is the format of one picture dot. The mask is then placed over scan line dot byte 5 times for each horizontal dot position and *DOTX* is called. The whole process is repeated for all 7 bytes of character dots.

7. *BACK*: The *BACK* routine is used to insert scan lines of background into the picture, onto which characters can be overlaid. This routine is selected by use of the *CHART* routine.

64 Gray Level Program

For those of you interested in duplicating my experiment with picture gray levels, the software is included in Fig. 3. The routine was assembled to run in more than 20K of memory. The routine includes a mini-monitor, and four program options can be selected to allow coresident operation with the other software. The software is well commented and requires no additional discussion. One patch must be included if you plan to use the routine. The jump-to-print option of the MOD routine must be changed to jump to this routine (see statement 766) of the source code.

The routine options can be selected by typing:

R = Receive a picture into memory (64 gray levels).

X = Xmit a picture from memory 4 times (64 gray levels).

P = Print a picture from memory formatted by 128/128 or 256/128 with 16 gray levels.

M = Jump to the monitor at location 0F01.

System Requirements

Fig. 5 is a memory map of the entire programming

package. As discussed earlier, the memory requirements range from 12K to 24K, depending on the program features required.

Two MIKBUG-type calls are made from the software package:

INEEE (E1AC)—Input a character from the keyboard into the A accumulator.

OUT (E07E)—Output an ASCII string from memory to the display until a 04 hex is reached.

If another CPU card speed is used which differs from the basic SWTPC 6800 clock (1.7971 MHz), a number of program delay functions must be changed. Table 1 is a list of these constants. Other delay constants may have to be changed, however. These values are contained in my most recent articles.[1]

The operation of the program is quite simple. In order to select all of the enhancement modifications (see Photo 7), the print function should be used in the enhancement program. If the 64 gray level program is installed, it can be selected by the print option in the MOD menu. As in the basic enhancement program, the start address is 0F01. This should be loaded in address A048,49 and the letter G typed, to execute the program.

Acknowledgments

The development of this program took a fair

NOTE to 73 Subscribers

From time to time 73 Magazine makes its subscriber lists available to carefully-screened companies and organizations whose products, services or information may be of interest to you. In every case, we must approve all organizations wishing to mail to our subscribers. In every case they receive a list of names and addresses only—no other information we may have is divulged. Each organization may use the list only once and agrees never to make any personal or telephone solicitations from it.

The overwhelming majority of our subscribers appreciate this controlled use of our mailing lists—it helps them shop conveniently by mail for products and services they need, often at substantial savings. A few people prefer their names not be used. It is to them we address this message.

If you do *not* wish to be a part of this service, please complete the form below . . . your name will not be used in this manner for any reason.

(If you asked us in the past to remove your name from our lists, there is no need to repeat the request.) Please allow about six weeks for your request to take effect.

☐ I wish to have my name removed from the list of subscribers receiving mail other than the regular subscription to 73 Magazine.

amount of work. Two amateurs assisted me in this project by reviewing my article and evaluating the software on their systems. I would like to thank Geoff Chapman VK2AIT and Doug McArthur VK3UM for their help. As a result of my first article,[1] Geoff Chapman has developed a printed circuit board which is plug-compatible with the SWTPC 6800.[6] For additional information on cost and availability, send him an SASE in Australia; elsewhere, include IRCs for details. I also would like to thank Walt Cole for his assistance on the photography. If you decide to write me a letter with additional questions, please enclose an SASE. ■

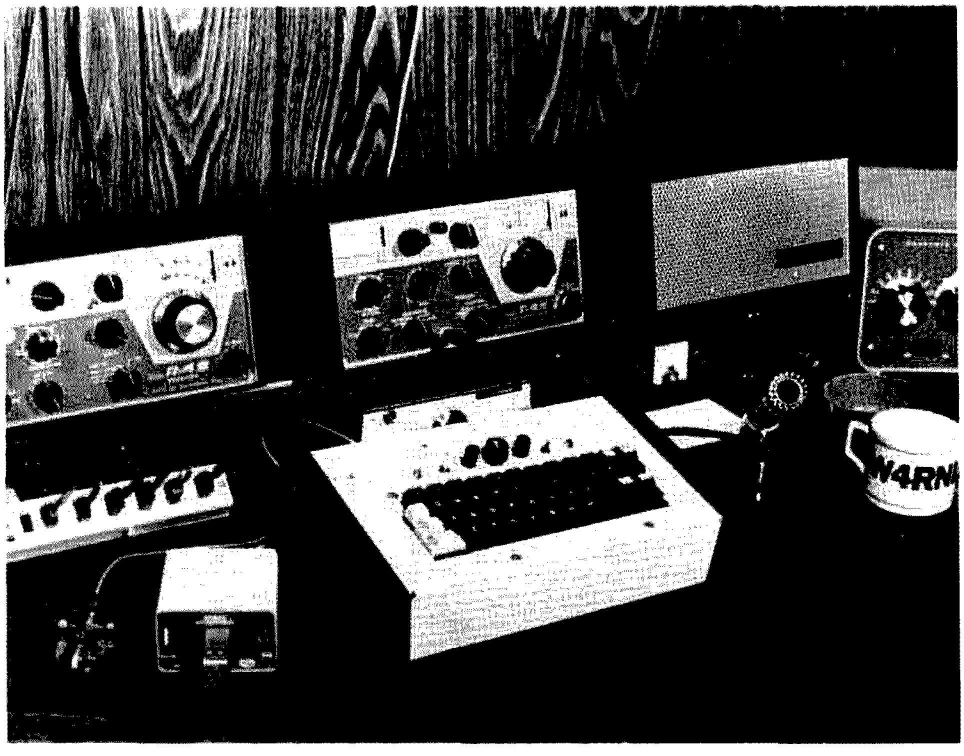
Son of Keycoder

—an even simpler CW typewriter

There are many good designs for CW typewriters. They have been designed around various levels of IC technology from RTLs to PROMs. One of the best is W9UBS's TTL version, which makes use of the W9TO encoding system. This machine, dubbed Keycoder I, was described in the July, 1976, issue of *73 Magazine* by WA9VGS. It represents a conversion of W4UX's RTL-based Touchcoder II, which was written up in the July, 1969, issue of *QST*. K6BS restocked the machine with CMOS chips (see *73 Magazine* for October, 1976), and perhaps his version should be called Keycoder II. It seems that one problem facing anyone developing a CW typewriter is coming up with an original name for it.

If anything, my version of the TTL CW typewriter should be called Son of Keycoder I. In fact, the mill is less a new design than a wedding of two designs: the electronics of W9UBA/WA9VGS (with encoding *a la* W9TO), and the old-fashioned diode matrix. It provides a lesson in the adaptability of designs, and may provide some useful ideas for those faced with modifying designs to suit local junk box conditions.



This is a view of the code typewriter amidst other CW-making equipment in the W4RNL shack. The photo also shows clearly how the use of wood end pieces will obtain the slope needed for the keyboard. To enjoy CW, everything on the operating table (including the coffee cup and ashtray) is needed except the mike. The 25-year-old J-38 and the Codax keyer are used often in an attempt to send CW as perfectly as does the typewriter.

What Makes the Machine Work

Fig. 1 shows the schematic diagram of the typewriter used here. With the major exception of the method of setting the flip-flops, the circuit closely resembles the one specified by WA9VGS. Included is the transistor output suggested in the original article as an alternative to relay output. The suggested means of construction, using the Radio Shack Universal Display Board (P/N 277-108), proved so easy that this same board has been used for other projects. The busses on this board can be chopped into short subsections, thus increasing the number of available lines far beyond eight.

Let us briefly review circuit operation, just to get a feel for the machine. When any key (letter, number, or prosign) is depressed, two things happen. First, the SCR fires 5 volts through the diode matrix, through one or more of the inverters, and sets some of the flip-flops. For example, for the letter A, f-f 2 and f-f 3 are set. The presence of a

set on any flip-flop—by virtue of the sequence of gates—changes pin 6 of the 7400 to a low, which closes down the SCR until the letter is complete. When all the flip-flops are clear, pin 6 of the 7400 goes high, readying the SCR for another letter. In the meantime, the anode of the SCR has charged up for the next letter.

Second, when pin 6 of the 7400 goes low, the NE555 clock turns on and produces a series of dots. These go to f-f 8 and to pin 5 of the 7402. F-f 8 is the dash generator whose output goes to pin 6 of the 7402. This section of the 7402 sums its inputs and sends them to pin 11, a different gate of the same DIP, where they are again summed with the output of the gates running from f-f 2 through f-f 7. If both pins 11 and 12 of the 7402 show a low—the case where we have a dot or dash—the output drives the two-transistor circuit to key the transmitter. The output circuit is set up for blocked-grid keying, i.e., negative voltage. Relay circuits are available for keying other voltages.

The sort of output that occurs is a function of which and how many flip-flops from f-f 1 through f-f 7 are set. If any one or more flip-flops from f-f 2 through f-f 7 are set, then a sequence of dots is generated as the set moves right, with the last one stemming from f-f 2. If f-f 1 and any other flip-flop (from f-f 2 through f-f 7) are set, then a dash is generated. This occurs because pin 10 of the 7402, having received a low on both its input pins 8 and 9, enables the dash generator. Once the dash is enabled by keying the dash generator, the set on f-f 1 drops out since it has no other flip-flop to its right to pick up the set. If only f-f 1 is set, as is the case at the end of every letter, then a silent E is sent; that is, the dot generator goes through one more complete cycle, but the output summing gate (pins 11, 12, 13 of the 7402) is disabled due to a lack of a set on any of the other flip-flops, f-f 2 through f-f 7. This ensures the proper spacing between letters. Thus, we have dots, dashes, and letter spacing, with the negative half of each cycle of the clock providing self-completion of each.

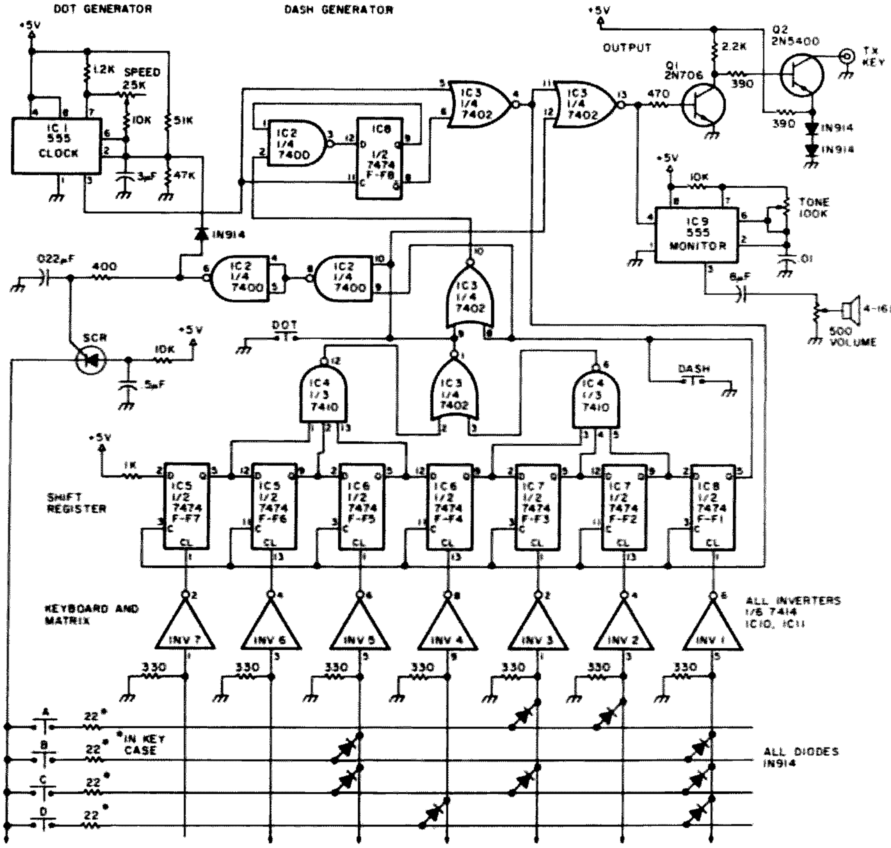


Fig. 1. Schematic diagram of the CW typewriter. Only part of the keyboard and matrix is shown. Not shown on the diagram is the pin 14 Vcc (+5 volts dc) and pin 7 ground connection to every IC. Every IC should have pin 14 bypassed with a .01 disc ceramic. Q1 can be almost any NPN transistor; Q2 should have a rating of—100 volts or better (see the article by WA9VCS for a list of suggestions). For this project, by all means, use IC sockets.

The output, pin 13, of the 7402 also drives another NE555 set up as an audio oscillator for the purposes of monitoring and practice. Getting used to a code typer does take some practice, since the rhythm of Morse code is quite unlike the rhythm of touch typing. In fact, having patience during letter formation, while still being ready for the letter after that surprisingly short E, is the hardest task. The results, however, bring rave notices on the air.

This circuit review has been kept brief, since full pulse-by-pulse details of circuit operation are contained in the Touchcoder and Keycoder articles mentioned above. Both discussions are complete and clear, and I heartily recommend them.

My unit differs from Keycoder I in three specifics: (1) setting the flip-flops (a major change); (2) the SCR circuit (a minor change, but a major problem in the minds of some builders), and (3), the method of cabinet construction (a personal and economic matter). Discussion will be confined to these areas.

From Keyboard to Diode Matrix to Flip-Flop

The authors (or sires) of Keycoder specified a cost of about $60 to $70 for their unit. Much of this cost was for the keyboard and case. If you have a keyboard and can make a case, the cost can be halved. Just this thought prompted me to use an old keyboard given to me long ago.

My keyboard is made up of individual switches about an inch and a half long, each of which contains a series resistor of 22 Ohms. As is, this switching system will not drive the

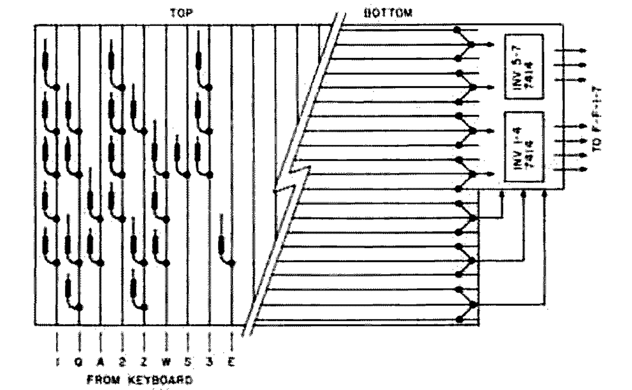

Fig. 2. Sketch of the Matrix Board. On the left is the topside showing the copper strips for the leads from the keyboard. Note that with most keyboards, the leads will not appear in alphabetical order. The unterminated diode leads pass through perforations in the board to be soldered to the transverse strips on that side. The right half of the sketch shows an X-ray view of the underside. Multiple lines serve each inverter, allowing greater flexibility in diode placement. Inverter pins for input and output are shown in the schematic. Any number of alternatives—from etched circuit board to copper wires—may replace the copper-bonded adhesive plastic used here.

toroid system used by Keycoder. Since the SCR pulse to ground through the toroids runs high current, the voltage drop across the resistor leaves too little for reliable setting of the flip-flops. The choice was clear: Either cut open 44 individual keys, short the resistor, and reclose with glue, or find an alternative method of triggering the flip-flops.

The surest method of getting a signal through the switches is to run a high through them, triggering some device that needs a high. The low current requirements for this state provide an insignificant voltage drop through the switch resistors. However, the flip-flops (7474s), typical of TTL technology, get set on a low. Therefore, on the diode matrix board there are shown seven Schmitt trigger inverters, packaged in two 7414s. This leaves several inverters unused, since they come six to a DIP. The Schmitt triggers may not be strictly necessary. Regular inverters (7404) might do just as well, but the 7414s have a snap action that cleans up minor glitches that might be caused by line variations or soft keying in the 22-Ohm switches. They have worked beautifully.

When no key is pressed, the input to the 7414s shows an open circuit rather than a low. Therefore, 330-Ohm resistors were run from the inputs to ground to hold the inputs low until a letter is keyed. The value of the resistor is non-critical, but something in the 300-Ohm ballpark should be used. Since the path of the high is through the switch resistor and the input resistor to ground, the voltage drop across the switch resistor is held to well-under ten percent of the 5-volts Vcc. Even with the voltage drop across the matrix, the minimum voltage needed to set the inverter high is more than met. Thus, the inverter output shows definite lows and highs to keep the flip-flops set inversely at high and low as needed.

Between the switch and the inverters is a diode matrix with some 130 1N914 equivalents soldered to it. After wiring the board, I am convinced that it takes only about the same amount of time to assemble a diode board as it does to string more than 40 number 30 wires through and/or around 7 toroids. The work goes fast if you do three things. First, have your board set up for easy work. Second, check each diode with an ohmmeter before soldering. Third, check the diodes for each letter immediately after soldering.

The second and third chores are quickly accomplished, but are essential. Toss out any diodes that do not show a very large difference between forward and reverse bias. Leakage can create erratic keying. These precautions provided perfect first-time operation of the code typewriter, so I am unsure what the consequences of a leaky diode might be. However, in a commercially made keyer, one such diode provided dots that sometimes became dashes, much to the chagrin of those trying to copy me. Finding the problem cost me several hours of hunting.

Setting up the diode matrix board is not difficult. Those who like to etch circuit boards can set up 44 thin lines on one side and seven broad lines on the other. The inverter ends of the diodes can pass through holes between pairs of thin lines, and emerge in the middle of a broad line on the reverse side. Other methods are equally possible. I had access to clear plastic with copper lines permanently bonded to it. The reverse side was sticky, and adhered perfectly to perfboard (.100 × .100 hole spacing). A four by seven inch board allowed all 44 letter lines to fit the length, while transverse lines were run across the back. To keep diodes well separated, I used three lines per inverter, wired in parallel. For keys like zero, which need six diodes, the spacing made assembly and any future servicing a matter of ease. Diodes are mounted on the 44-line side with their inverter leads puncturing the plastic to pass through a perf to the other side. The 44 leads to the keyboard make a dandy hinge (if not flexed too often), and the matrix board folds back under the keyboard. Even with a sheet of insulation between boards, the matrix adds less than a half-inch depth to the keyboard.

Fig. 2 shows a diagram of the principles of the matrix board. Here a drawing is definitely clearer than a photo. Although much maligned in recent years, with the advent of PROMs and the like, diode-matrices still have much to recommend them. Should something go wrong, a replacement diode costs a few cents; a replacement PROM costs much more and creates a much longer downtime, unless one can afford to have a spare programmed memory. Also, the diode matrix allows me to change my mind and revise the keying setup in just a few minutes; PROMs are permanent. In comparison to toroids, there is not much to choose from, except that diode matrices are generally voltage-fed devices, whereas toroid transformers demand a fairly high current. Of course my typewriter matrix requires only low current; it may be of use to remember diodes for other similar applications, where current is not available or needed in large doses.

One ham friend has characterized my diode-driven TTL keyer as a marriage between the slightly advanced Cro-Magnon and the very regressive Neanderthal. I prefer to think of

it as crossbreeding for the best characteristics of both. Neanderthal man, after all, had some socially redeeming characteristics.

Programming the matrix is no problem. The toroid threading chart provided by WA9VGS is also a diode chart for this keyer. Wherever there is an X on the chart, run a diode between the letter line and the proper inverter line. For convenience, Fig. 3 reproduces the character generation table.

Something About SCRs

If you were to compare the SCR circuit of Keycoder I with the circuit used here, you would find only one small difference. Instead of a capacitor of 1.5 uF from the SCR anode to ground, the value given here is only .5 uF. Actually, the value is uncritical, and anything from .25 to 1 uF will work.

The SCR circuit has one function: to provide a quick shot of voltage through the key and diodes to the proper inverters, and then to shut down. When there is a letter being processed by the keyer, pin 6 of the 7400 holds the SCR gate low, inhibiting current flow through the diode. However, a low on the gate will not cut off current flow unless the voltage on the anode also drops below minimum. The resistor in the 5-volt line, and the capacitor to ground (10k and .5 uF respectively), allow the voltage on the anode to drop as a key switch is closed, thus cutting off the SCR when its gate goes low. As the capacitor recharges, the low gate prevents the SCR from conducting until the keyboard clears, at which time pin 6 on the 7400 and the gate go high; then the SCR has an open gate and full voltage, ready for another key to be struck. If the same key has been held closed, the SCR will conduct through it for a repeated letter.

Fig. 3. Diode matrixing table. An "X" indicates that a diode is wired from the character line to the inverter-flip-flop line (INV/FF). Thus the proper flip-flops are set to generate the indicated character.

The reason for this explanation is that many hams view SCRs as strange devices. Where they will substitute tubes and transistors freely, they fear to try substitutions for unfamiliar devices. In the given circuit, almost any hobbyist-grade SCR will work. From a package of five from Radio Shack, each having a different current rating, not one failed to work properly—once I had sorted out the cathode and anode leads, and quit installing them backwards! For the diode matrix system used here, a 15-volt rating was plenty, and the current demands are small. For the toroid application, as in the original Keycoder, somewhat higher ratings may be useful—say, 30 volts at half an Ampere. Since the diode matrix does not draw much current, a large capacitor across the anode of the SCR is unneeded; its value should be only large enough to hold the anode voltage down until the gate is cut off with a low, i.e., until the 7400 gate (pin 6) has registered that something is in the flip-flops. Some nanoseconds are all that is needed for this to happen. No new pulse can then interfere with the processing of the letter in progress.

SCRs have many other potential applications for voltage control in digital circuits. If the basic operating order of SCRs is remembered, they should become as useful and familiar to hams as transistors and FETs.

The only other circuit

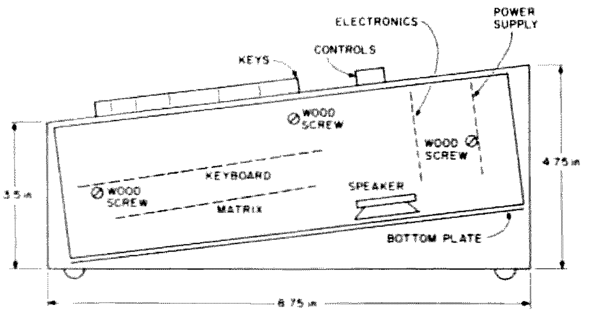

Fig. 4. X-ray view of end panel showing the alignment of the chassis to achieve the proper slope for the keyboard. The speaker mounts on the bottom plate. The dashed lines show the approximate placement of the power supply, main electronics, key switch, and matrix boards. Three half-inch wood screws hold the chassis to the wood end pieces cut from one-by-six. Rubber feet protect the operating desk.

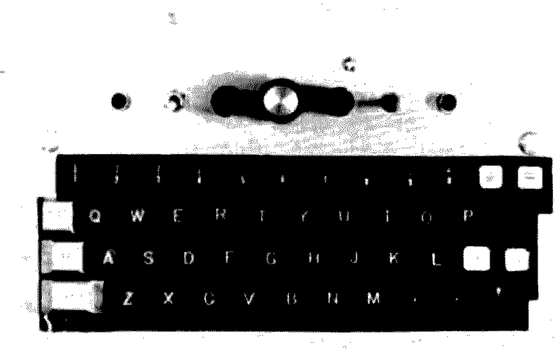
notes are the following two. First, a DASH line is added to the DOT line of the original. It works by grounding pin 8 of the 7402 along with pin 9, i.e., by pressing both the DOT and DASH keys together. (Using a diode across the DOT and DASH lines did not work, since the low remains above the diode-voltage drop, and this causes erratic dashes when letter keys are pressed.) The only practical use of this is to test the dot and dash generators, and to demonstrate to prospective hams the distinction between dots and dashes. Holding the DOT key closed, then keying and unkeying the DASH line, produces a string of alternating dashes and dots.

Second, a SPACE key has been provided. It keys the silent E, i.e., only the last flip-flop (f-f 1). For on-the-air use, this key has no function, but it is useful for keying serial input memories or Morse-to-ASCII converters which are tied to the typewriter clock. The space ensures proper word separation; paragraphing might be accomplished by some related means, such as a sequence of three successive spaces. In this unit, the space bar was removed and the space function moved to the key in the lower left hand corner of the keyboard, which simplified construction.



This is a close-up top view of the code typewriter. The controls above the keyboard are, from left to right, the ac pilot light, power switch, volume control, speed control, tone control, tune-up switch, and tune-up pilot light. Keys with white squares were labeled by using adhesive address labels with a transparent tape cover; all were typed and then cut to fit the keys. The DOT and DASH keys have had their internal resistors removed.

Construction Notes

Since part of the project included cutting costs, the case is home brew. As the photograph shows, the case is made from a 12-by-8-by-3-inch aluminum chassis base. The depth was made necessary by the length of the key-switch bodies. The power supply is edge-mounted, in the upper right corner as you look at the photo. The main electronics board also is edge-mounted just above the row of switches and knobs. The SCR and output circuits are mounted on separate pieces of perfboard, since some breadboard experiments are occasionally tried with them. Leads between boards are long so that any board can be removed for checking without unwiring the circuit. No rf interference was noted when I used the unit with either the Drake transmitter or the Heath linear.

The switches on my keyboard are tilted to present the operator with a tiered effect. This resembles the old-fashioned manual typewriter keyboard. The chassis had to slope, therefore. After cutting the keyboard hole with a saber saw, I built two wood end-pieces to hold the chassis at the correct angle. They also serve to elevate the rear underside of the chassis, which is covered with a bottom plate of scrap perforated aluminum. The monitor speaker is held to this plate by four clips, and the angle of the case projects the sound into the crowd of future hams eagerly taking code practice. A little stain and varnish finished the end-pieces to a soft shine, while several light, spray coats of light blue finished the cabinet. Fig. 4 provides a cutaway drawing to show how the end-pieces fit to the chassis to provide tilt in a simple but effective way.

The only item purchased for the cabinetry was the chassis base. Still, visitors to the shack seem to find the case striking, despite my poverty of skills in metal work. I think the reason is the use of a little wood. There is something about the use of natural materials in home brew projects which humanizes them a bit. They are not just plastic and metal products of technology and mass production (although some modern equipment deserves high grades for industrial design); they are the end result of personal craftsmanship. There is no need to copy commercially-built items to the last detail; indeed, one probably should avoid trying to do this. The manufacturer has manufacturing reasons for his choice of materials and appearance; likewise, the personal craftsman should have at least a few personal reasons for the materials and appearance of his projects. Money-saving is not a bad reason, for a starter.

While these notes may not add much to the span of modern technology, I hope they have accomplished a few things. First, they are a reminder that designs are adaptable, with a little effort, to what you have available. Second, they resurrect the diode matrix from threatened oblivion. Third, they may encourage hams to try SCRs a little more often. Fourth, they are a reminder that home brew products are not just second best to manufactured ones, but in some ways often are superior.

Finally, perhaps these notes may encourage a few others to try their hand at building what may become the "Grandson of Keycoder I!" ■

Sloppiness Will Get You Nowhere

—organize your coax

If you are like me, all the suggestions given by friends on how to route coax into the QTH don't meet your standards—or those of your wife. Holes in window panes, walls, and window frames just don't look right and are hard to patch if one moves. The solution I found is relatively simple and very easy to disguise if the equipment must be removed later.

I terminated my coax under the eave of the house, using an SO-239 connector for each coax cable. The SO-239 connectors were mounted on a metal plate, and hood-type shields were used on the rear of the connector to prevent rf leakage between coax leads. I also went to the expense of connecting a lightning arrester in each line at the plate—and, of course, the plate was well grounded.

A hole large enough to provide clearance for the rear of the connectors and smaller than the exterior dimensions of the plate was cut in the plywood under the eave of the house, and the plate was mounted in place so that it covered the hole completely. Several wood screws were used to secure the plate to the plywood.

Now, you ask, what is so easy to patch about a 2-inch x several-inch hole? Easy—just purchase an inexpensive attic vent plate at your nearby hardware store to properly cover the hole when it is time to move. It might be a good idea to visit the hardware store ahead of time and measure common sizes of vents that are available in your area so that you do not make the hole the wrong size or shape to cover.

Now that you have accomplished the feat of gaining access to the interior of the attic for your coax, how do you feed it down through a wall without making a mess? Another easy solution: Visit your friendly hardware man or electrical parts warehouse and purchase an electrical wall box such as those in which wall outlets and light switches are mounted. If the salesman is competent, he can sell you the box for the type of wall you have in your house. Also, buy a blank cover for the box, if you want, and you will be ready to cover the box if and when you move.

Locate carefully the place where you want to mount the box. It should be mounted in the wall at the same height above the floor as all other wall boxes. In the attic, measure carefully from known reference points and drill a hole vertically down into the wall directly above the location for the box *before*

cutting the hole for the box in the wall. Drop a weight on the end of a string into the hole and play it out until the string goes slack. Mark the string at that point, remove it from the hole, and measure from the mark to the bottom of the weight. If the measurement is the same as the measurement from the floor to the top of the wall, plus or minus one or two inches, then you are in business. If the measurement is shorter by two or three feet, it is obvious that there is an obstruction of some sort in the wall at the location you have chosen, and you must move left or right several inches and try again, drilling another vertical hole from the attic into the inside of the wall.

When you have found a location that will allow the coax to be fed from the attic down the inside of the wall, cut the opening in the wall at the proper height for the electrical box. Feed the coax through the cutout at the back or top of the electrical box as far as necessary and tighten the clamp to secure the coax. The box now can be mounted in the wall. If only one or two coax cables are used, a blank plate can be fitted with the appropriate number of SO-239 connectors and mounted to the box to make a neat and XYL-approved installation.

My installation consists of a bundle of 8 cables, and I used a double-width wall box without a cover. A desk and radio rack are in front of the box where it is installed, so I did not bother with using a cover. When we move, I will cover the empty box with a double-width blank cover, and the hole in the wall will be neatly concealed. ■

The Satellite TV Primer

—thousands watch satellite TV every day . . . here's how they do it and what they see

Robert B. Cooper, Jr. W5KHT
Rte. 5, Box 364
Guthrie OK 73044

Amateurs worldwide can be justifiably proud of amateur achievements with our noncommercial design, construction, and operation of space repeater/relay stations. The amateur fraternity's OSCAR-series satellites, and, more recently, the Russian RS-series satellites, have shown the commercial space communications world that gold-plated multi-million dollar space programs are not essential to the establishment of routine, predictable, space communication programs.

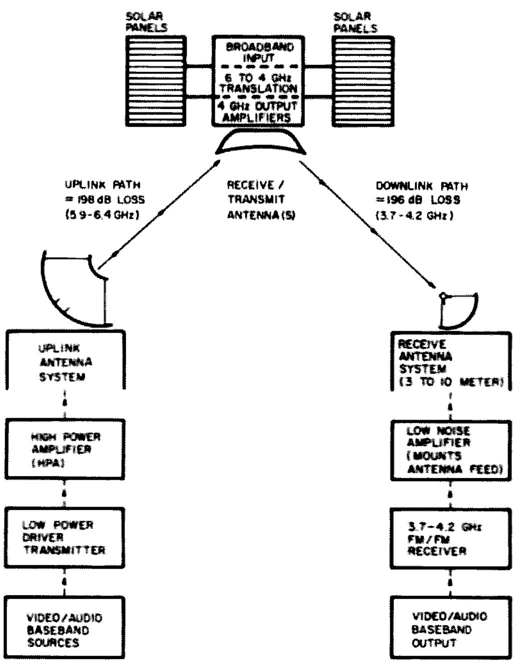

Fig. 1. How the geostationary satellite path works. Uplink transmitters send signals to appropriate bird in 5.9- to 6.4-GHz range. Within the satellite, the uplink signals are processed and downconverted to the 3.7-4.2-GHz range. The satellite is broadband processing until the final (single channel/transponder) output stage where individual transponders have their own 5-Watt peak power TWT amplifiers.

The amateur's appetite for challenge and his ingrained ability to achieve satisfactory results with equipment fashioned on the kitchen table—for budgets measured in the tens or hundreds of dollars rather than in the millions—has been a trademark of amateur activities since the earliest days of transcontinental communications. In a nutshell, amateurs have proven again and again through the history of communications development on Earth that the will to succeed is often a more powerful tool than unlimited budgets and large teams of technicians and engineers.

And history has a way of repeating itself. Geosynchronous satellites are a case in point.

To date, mankind has utilized four different types of satellites to achieve communications via "space stations." In the amateur world, the most familiar satellite is the low-orbit constantly-moving (with respect to a point on earth) active relay station symbolized by OSCAR. OSCAR follows in the footsteps of TELSTAR I (a commercial satellite launched in July, 1962, by Bell Labs) and RELAY I (a NASA-launched low-orbit satellite put into space in December of the same year). Low-orbit satellites are placed into a launch sequence which takes the satellite around and around the earth at relatively low altitudes (typically, within a couple of hundred miles of the Earth's surface) at a forward speed which allows them to circle the Earth

completely in several hours. Because the Earth is spinning on its own axis at the same time the satellite is circling the Earth, a low-orbit satellite crosses over different regions of Earth with each "pass"—a fact well known to OSCAR buffs.

Perhaps the next most-commonly utilized satellite is the Earth's moon, a "satellite" first used for communications in 1946 by a US Army communications team, with equipment originally conceived in the closing years of World War II. Amateur use of this particular satellite was pioneered in 1953 when moon echoes were first successfully received on the 144-MHz amateur band.

In our 1979 world of sophisticated rocket-launched active satellites, one may have some difficulty including the moon in our discussion of satellite communications, but it fits the mold nonetheless. In fact, the use of a passive relay device (the moon or similarly passive object) continued to spark interest in the scientific community up through 1963. In 1957, the moon was first utilized for passive relay of two-way voice communications. In August of 1960, a NASA-launched balloon satellite some 30 meters in diameter achieved a 1,600-km elevation orbit, producing the first satellite relay of both telephone and television communications (ECHO I). Even as late as May, 1963, MIT (in cooperation with NASA) launched another type of passive relay satellite: The West Ford Project put into space approximately 400,000,000 "dipoles" (thin strands of reflective material). ECHO I provided NASA, Bell Labs, and the California Jet Propulsion Labs with the opportunity to test 1- and 2.5-GHz FM transmissions (telephone and television) by directing high-power transmitters and large parabolic antennas at the mid-range (height) of the elevated passive reflector. A measure of success was achieved, while the multi-million-dipole West Ford Project was far less successful.

Yet a third form of satellite had been launched in 1957 by the Russians. SPUTNIK I was a low-orbiting satellite with its own self-contained capsule message on board. As the satellite circled the globe it transmitted the Morse message "Hi" over and over. The fact that it had been programmed to transmit in International Morse code and in English was not lost on anxious American defense and security personnel.

The mold created by SPUTNIK actually continued for several years. The United States rushed a satellite into low orbit in December, 1958 (SCORE, a US Air Force experimental satellite), with a tape-recorded Presidential message on board—just in time for the holiday season.

The first use of active electronics on board a satellite came in October, 1960, when the US Army launched COURIER 1B, a satellite that achieved a maximum altitude of 1,000 km, and was outfitted with high-speed magnetic tape equipment. COURIER was capable of being ground-loaded with voice and other communications as it passed over one remote location, storing the data, and then releasing it on command from a second earthbound terminal. This was hardly real-time communications, but it did fill both scientific and political needs of that era.

Another type of low-orbit "first" also happened back in 1960. In April of that year, NASA launched the first meteorological observation satellite (TIROS I) at a 700-km elevation. This weather satellite operated long enough to transmit back to Earth more than 22,000 meteorological pictures in about a two-month period. While this satellite was generally capable of what would today be called low-resolution pictures, it nonetheless did attract the interest of the general public when an inventive journalist called it "the world's first spy in the sky." And that message was hardly lost on defense and security planners worldwide.

During most of the late 50s and early 60s, communication via satellites was done in the lower VHF range or even the HF range. SPUTNIK I beat against WWV's 20-MHz assignment, SCORE sent a Presidential greeting via VHF, and TIROS transmitted cloud-cover and landmass black-and-white pictures via a frequency range just below our amateur two-meter band. All of this was destined to change when our fourth type of satellite was first launched in July, 1963. The magic word was "geostationary."

Our OSCAR and other low-orbit satellites provide a useful communications relay largely because they are predictable. Once the parameters of the launch are known (i.e., the intended altitude and inclination, or angle of trajectory), telemetering from the "bird" allows ground control stations associated with the launch to calculate with a high degree of precision

Uplink frequency range	5.9 to 6.4 GHz
Downlink frequency range	3.7 to 4.2 GHz
Modulation	FM video with FM subcarrier audio
Bandwidth per transponder	36 MHz*
Peak deviation	10.75 MHz*
Top of video baseband	4.2 MHz
Aural subcarrier frequency	6.8 MHz (6.2 MHz)**
Deviation of subcarrier	75 kHz
Top of audio baseband	15 kHz
Channelization	WESTAR, ANIK, vertical on SATCOM—40-MHz wide, each in even steps with transponder 1, 3700-3740; horizontal on SATCOM interleaved, with transponder 2 at 3720-3760.
Typical (free) space loss	196 dB
Typical EIRP	37 dBW WESTAR on boresight; 36 dBW SATCOM on boresight; 36 dBW ANIK on boresight. INTELSAT, 22 dBW global beam, 26 dBW hemispherical beam, and 29 dBW spot beam.
Polarization	WESTAR, ANIK—linear horizontal; SATCOM, COMSTAR—linear, horizontal, and vertical; INTELSAT-circular (either sense).

*Transponder 23 on SATCOM F2, utilized to relay television programming to Alaskan Bush Terminals, uses a split- (half-) transponder format; all INTELSAT transponders carrying video also utilize a split- (half transponder working) format.
**Aural subcarriers for INTELSAT and transponder 23 on SATCOM F2 may not be on the same transponder as the video.

Fig. 2. Geostationary Satellite System Parameters. With the exception of some Russian RADUGA-series geostationary satellites, this data pertains to all operating satellites in this service providing television relay.

the period of rotation about the Earth and the precise overfly route of the satellite. Given this data, it is no big trick to have the proper ground station equipment in operation and the satellite-accessing antenna pointed at that spot on the horizon where the low-orbiting satellite will first appear as it travels around the Earth. However, all low-orbiting satellites do move, and the ground stations that access data from or transmit data to such low-orbiting satellites must be capable of tracking the satellite as it passes from the access horizon through the sky and then out of view once again over the opposite horizon. It is a little bit like having a totally-predictable ionosphere at work at HF—something we have never achieved, incidentally.

Way back in 1945, an "amateur" with both an inventive mind and an amazing understanding of geophysics prescribed a solution to this low-orbit problem—long before low-orbit satellites were even dreamed of! His name was Arthur C. Clarke, and in *Wireless World* in 1945 Clarke postulated that if man could launch a "microwave repeater station" into a precise orbit position some 22,300 miles above the equator, the forward speed of the satellite would exactly match the rotational speed of the Earth on its own axis. Clarke demonstrated, on paper, that such a satellite would "appear to stand still" to an observer on Earth. Clarke saw this stationary orbit position as a key to achieving instant worldwide communications on command, since one satellite could "see" approximately 40% of the Earth's ground surface area; a trio of such satellites, properly spaced around the Earth, could be interconnected in such a way that a ground station could communicate with virtually any other ground station in the world.

Such a satellite was successfully placed into orbit in July of 1963. It was called SYNCOM 2, and it connected nations together across the Atlantic from an altitude of 35,900 km. It had a forward speed of 11,200 km per hour, matching the Earth's rotation. With a capacity of 50 telephone circuits or one television channel, SYNCOM was the first man-built machine capable of interconnecting two or more continents simultaneously for real-time television.

Geostationary satellites (or geosynchronous, as they also are known), are what this is all about. More precisely, the present generations of geostationary satellites, providing real-time television relay throughout the world today, are what this is all about.

International vs. Domestic

The present generation's geostationary birds generally fall into two operational categories, International and Domestic. Fig. 1 summarizes the operation of both types.

Satellites intended for international relay are known as INTELSAT birds, and they are operated by an international consortium formed initially in 1965, with the launch of EARLYBIRD. Although only three (properly-selected) satellites are required to provide Earth-circling communications, INTELSAT presently operates a total of 12 such satellites; they are identified on the map in Fig. 3. There are three primary regions, or "parking areas," for the INTELSAT satellites: the Pacific Ocean area (generally around 180 degrees west or over the equator north of the Fiji Islands), the Atlantic Ocean area (generally between 0 degrees west and 35 degrees west, over the equator between Africa and the eastern tip of South America), and the Indian Ocean area (generally near 300 degrees west 60 degrees east, over the equator north of the Seychelles Islands). At least two separate satellites are positioned in each region, one as a primary or operational bird and the other as a reserve or secondary bird. In the Atlantic region and the Indian Ocean region, there are more than two INTELSAT birds parked, largely because of the high volume of commercial traffic in these regions of the world.

The present generation of satellites is of the IV (or 4) class—which simply means there were other generations ahead of them. These satellites are capable of handling 20 or so simultaneous television channels or some combination of television plus telephone (voice) or data channels. They all operate in the 3.7- to 4.2-GHz downlink (i.e., satellite-to-ground) frequency range, a range that is shared in North America and many other portions of the world by terrestrial point-to-point (telephone) or common-carrier microwave. They are fed input signal in the 5.9- to 6.4-GHz range (the so-called uplink path) from earthbound transmitters operating typically with 1 to 3 kW of transmitting power and very large parabolic antennas (40-100 feet in diameter) with gains in the 55-65-dB range. All of which make the 100-Watt erp requirement for access

Reader Service—see page 243

to OSCAR seem tame.

In our second family we have "domestic satellites," those intended for and licensed for operation within the borders of a single nation. Under international agreements reached in 1970 and 1971, the equatorial satellite "belt" has been broken into an "assignment table" where certain locations above the equator are reserved for INTELSAT-class birds while other locations are set aside for operation of domestic or non-INTELSAT satellites. These locations are specified in terms of the prime meridian (0 degrees, or Greenwich), and the equatorial region (from 70 degrees west—roughly due south of Boston—to 135 degrees west—roughly due south of Sitka, Alaska) are set aside for satellite parking of birds intended to serve North America. Within that arc there are presently 10 US and Canadian satellites in operation. The arc has been chosen to ensure that a satellite parked at either end of the arc can still see all or the majority of the North American landmass. Remember, just as with OSCAR, the reliable coverage of such satellites is limited to those portions of the Earth where line-of-sight contact

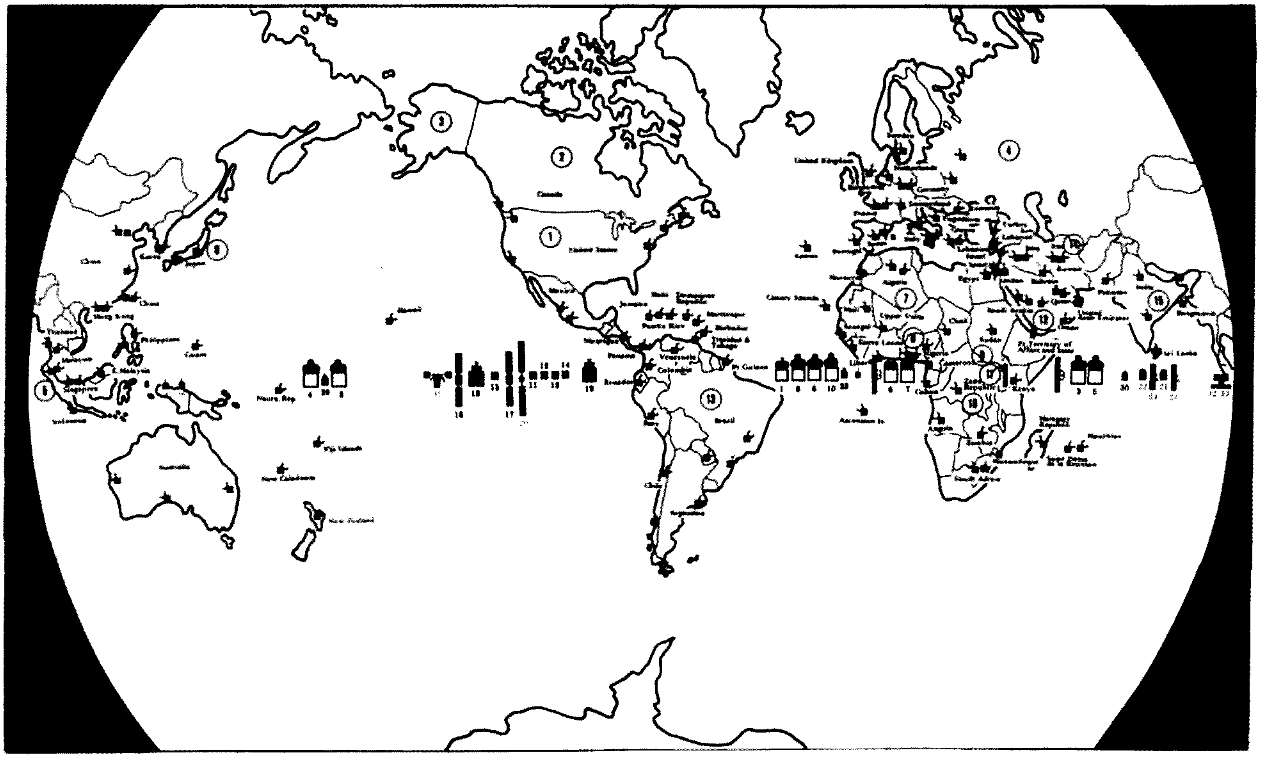

Fig. 3. Geostationary satellites and their locations. Equatorial parking locations of INTELSAT and domestic satellites providing television (plus voice and data) communications circuits are shown. Maritime satellites (which do not provide video services) are also shown because of high interest in their operation.

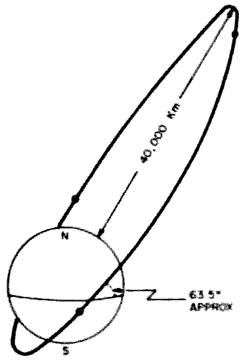

Fig. 4. Russian MOLNIYA satellites have been launched in an unusual inclined orbit resulting in elliptical orbits with a 12-hour period. By placing several satellites in the same ring, or train, virtually full-time service is maintained because of the length of the apogee period (8 hours) during which satellites appear (almost) to stand still to the ground receiving terminal. The system also provides coverage over the polar region, something not possible with equatorial-region geostationary satellites.

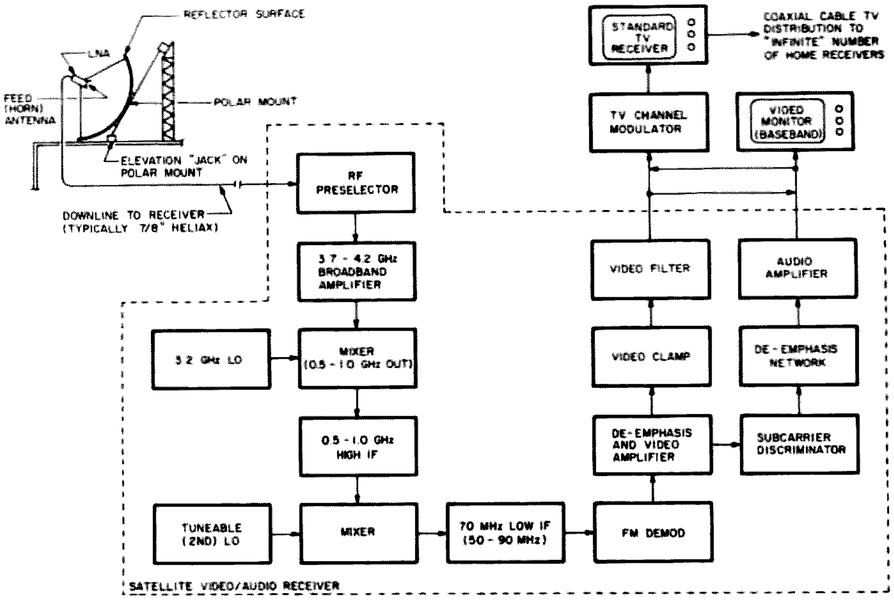

Fig. 6. Typical "small Earth receive-terminal" system (private or low-grade commercial) shows how the various component parts interrelate. The EIRP level present in a location determines the requirements for minimum size (i.e., gain) parabolic antenna, noise figure of LNA, and acceptable receiver i-f bandwidth.

can be achieved between the 22,300-mile-high satellite and the Earth receive terminal installed to access its signals.

Domestic satellites are fairly new in the satellite world. While more than 100 nations of the world now belong to INTELSAT and participate in its worldwide communications system, none of the member nations directly owns the satellites; they are owned and operated by an international investment consortium made up of both private investors and government agencies established in countries such as Nigeria to buy into the operation. Having bought in, the member nations are entitled to utilize the services of INTELSAT to interconnect their national telephone and data networks to the worldwide communications network, and to send out and receive television programming via INTELSAT. All of this is done on a very businesslike basis, with each user paying a use fee for the actual amount of satellite time the country makes use of. The domestic satellites operate on a slightly different principle.

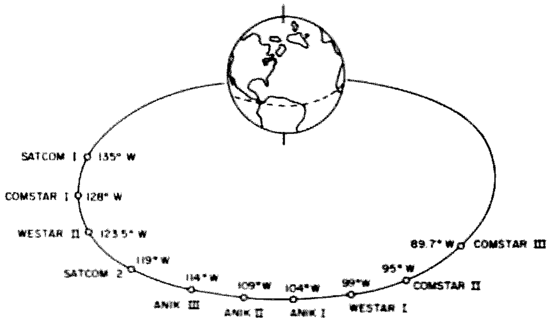

Fig. 5. United States and Canadian 3.7- to 4.2-GHz downlink-range geostationary satellites follow fairly closely to internationally-recommended 4-5-degree inter-satellite spacings established in 1970-71 by the United Nations. Satellites shown are only those operating in North-American service in this frequency range. Other satellites operating in other frequency ranges and serving North America are not shown. With the proposed launch of RCA SATCOM F3 this fall (scheduled to be spotted at 132 degrees), tests will be conducted to determine if closer (3-degree) spacing is feasible.

In Canada, Russia, and Indonesia, the respective governments have funded the design, purchase, and launch of their own communication satellites. Canada has four presently in operation, including one launched this past December. Canada, however, presently has only three "orbit spots" assigned to it, and one of the four will be retired shortly. The Canadian domestic satellites are utilized to provide telephone, data, and television communications to and from the less densely settled portions of Canada. This means that they are largely intended to serve the northern areas of the US, Canadian border provinces, plus the Northwest Territories and the Yukon. It is worth noting that with an equatorial orbit position, the horizon cuts off at the 80th degree north parallel; beyond that point, the bird cannot be "seen," so, in Canada's case, the ANIK-series satellites do not serve every nook and cranny of the country.

Indonesia has a pair of satellites purchased from the prime supplier of satellites in the free world, Hughes Aircraft Corporation. Indonesia was authorized to launch and operate their twin birds named PALAPA I and II, as a means of providing first-time communications (telephone, radio, data, and television) to the thousands of islands which make up the nation. However, the Indonesians have been

Photo A. "Novosti" or Russian news broadcast as received on an early model G8AKQ receive system with an 8-foot parabolic antenna. At the time this photo was taken, Birkill estimated his system receiver noise figure at about 3.8 dB (400 degrees Kelvin). He is within the 29-dBW contour from STATSIONAR. The satellite broadcasts on 3.89 GHz, well within the worldwide 3.7- to 4.2-GHz downlink range.

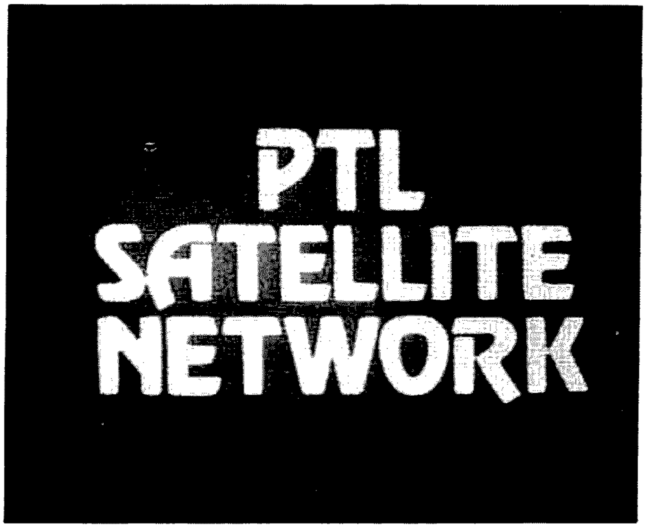

Photo B. PTL (transponder 2) is one of three full-time religious channels on the RCA SATCOM F1 satellite.

experimenting with leasing satellite channel space to other nearby nations, and television for the Philippines, Brunei, and other neighboring countries is relayed via PALAPA birds on a regular basis.

Russia's domestic satellites don't quite fit the mold of the balance of the world. The Russians first launched a domestic satellite system in 1965. The first Russian satellite was launched prior to the time the Russians had the capability to launch a heavy payload (2,200 pounds) into a geostationary orbit. So MOLNIYA I ("Lightning") was launched into an inclined, highly-elliptical orbit (see Fig. 4). This is a 12-hour orbit period with an apogee such that for approximately 8 hours per day the MOLNIYA bird appears to stand almost still with reference to Earth. By placing three satellites in the ring the Russians thus achieved many of the benefits of geostationary orbit without the precise orbiting equipment or launch power required for such a launch. More than 40 such satellites have been launched by the Russians, and one of the advantages of this approach is that there is coverage over the north polar regions, something not possible with equatorial geostationary satellites. In 1975 the Russians launched their first geostationary satellite (STATSIONAR) in the now-classic INTELSAT format. In the STATSIONAR series are two separate types of satellites: RADUGA, which is intended for both domestic and international telephone, data, and television relay, and EKRAN, which is a direct-to-the-home UHF-region broadcasting satellite. EKRAN operates at a much lower downlink frequency than other television-oriented satellites; a center frequency of 714 MHz (inside the US UHF television band, or, roughly, UHF channel 54). The onboard transmitter and antenna system create a very powerful ground level signal, such that simple yagi antennas provide first-class television to Siberia and other portions of far eastern Russia. Because of the location of this satellite (99 degrees east), it has a line-of-sight situation to portions of western Alaska and the Pacific, including Guam. Although the antenna is supposed to be "boresighted" on the UA9/UAØ region, amateur experimenters as far east and south as Rhodesia report reception from this powerful UHF-region television satellite.

The US Domestic System

By now, you may be getting the general idea that reception of geostationary satellites by amateur-constructed terminals offers a certain fascination. This may be the understatement of the year!

For example, how would you like to have access (via satellite) to *all* of the following in your own home?

1) Four of the nation's top independent television stations, such as Chicago's WGN, San Francisco/Oakland's KTVU, Atlanta's WTCG, and NYC's WOR?

2) Five separate pay cable services, including HBO (Home Box Office), SHOWTIME, FANFARE, HTN (Home Theater Network), and Warner's STAR CHANNEL?

3) Three separate full-time family/religion channels including PTL, CBN, and Trinity Broadcasting's KTBN?

4) A 13-hour per day Children's Television Network called Nickelodeon, created by the corporate family at Warner Brothers?

5) Over 1,000 hours per year of live sporting events from Madison Square Garden in New York, plus Notre Dame basketball, Penn State college football, and more?

6) A twenty-four-hour-per-day (!) all-sports channel?

7) A twenty-four-hour per day still-frame video news channel with accompanying audio from United Press International?

Too much television you say? Well, that's but the service list (early in 1979, and it grows monthly) on but a *single domestic satellite* serving North America. There are a total of ten such satellites with more than 40 such channels now in operation if you sum the video programmed services on the satellites serving the US and Canada.

The United States has followed a unique policy

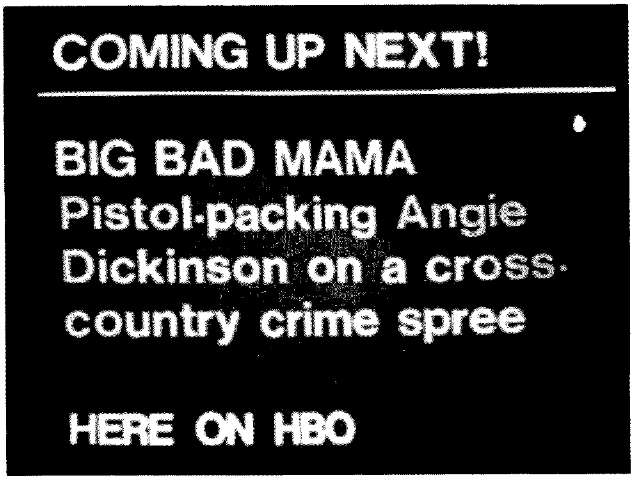

Photo C. HBO (Home Box Office) is perhaps the best known of the pay-cable services on satellite, although it is only one of five presently in service. Movies run 8-13 hours per day, are unedited, and run without interruptions (i.e., no commercials!).

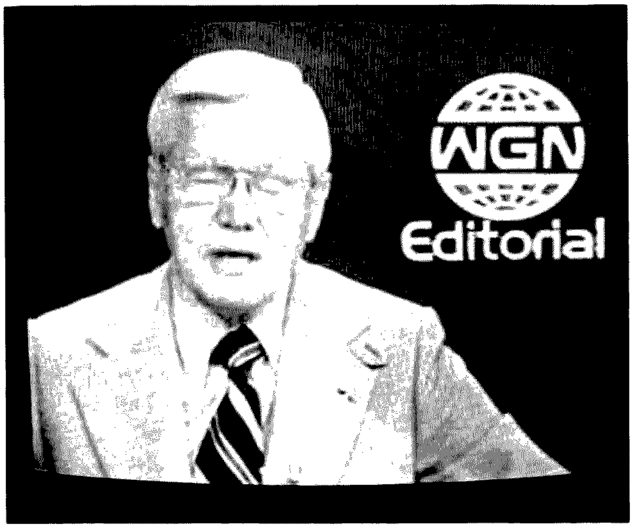

Photo D. Major market (i.e., big city), non-network stations, carried via satellite to cable firms across the country, provide a wide choice of movies, sporting events, and syndicated programs not seen on local televisions. Chicago's WGN, "the nation's highest-rated independent station" (or so they say), is presently on transponders on both SATCOM F1 and WESTAR II.

Photo E. SIN, or (the) Spanish International Network, is a consortium of US television stations in markets such as Miami, San Antonio, Los Angeles, etc., which have banded together to bring live Mexico City (Spanish language) programming into the US via WESTAR II. Bullfights, soccer matches, and a wide variety of Spanish soap operas, variety shows, and other entertainment fill the SIN channel approximately 12 hours per day.

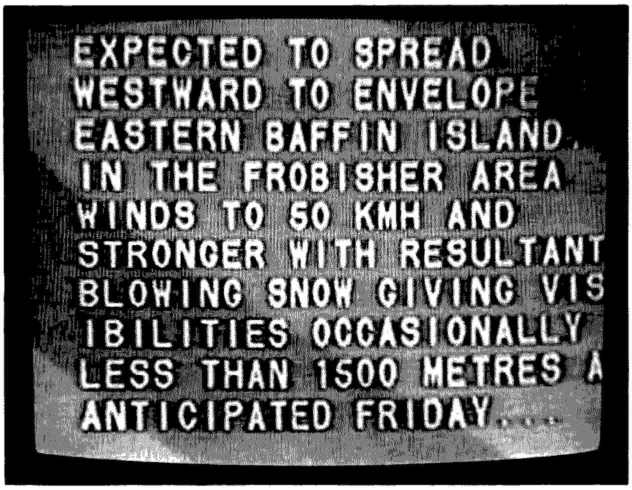

Photo F. Canada's three ANIK III television channels provide excellent diversion from US programming, since more than 50% of Canadian broadcasting now must be Canadian-produced. Weather reports for far northern Canada, Canadian coverage of US politics, and their own excellently produced documentary programs give one a broader slant on life than does US television.

of allowing private corporations to invest from 20 to 25 million dollars per satellite (for the bird itself), plus allowing these private corporations to rent launching services from NASA, in the hope that the firms launching such satellites can recoup their investments by renting out satellite relay services to qualified takers. A bird in orbit today represents between 40 and 50 million dollars invested. Compare that to OSCAR!

Following this opportunity, RCA has launched two such domestic satellites (a third is scheduled to be placed into orbit late in 1979), Western Union has launched three, and ATT/GT&E have launched three. Their orbital locations are shown in Fig. 5. Western Union satellites employ linear (horizontal) polarization, and they squeeze 12 separate video channels (known as transponders) of capacity into the 3,700- to 4,200-MHz downlink assignment. RCA and the telephone company birds (known as COMSTAR) employ dual polarization; they run one set of transponders in vertical uplink and vertical downlink and a separate set of transponders in horizontal uplink

Table 1. US/Canadian Domestic Satellite Channel Usage. Transponder assignments are not governed or made by the FCC (or DOC); they are subject to the engineering requirements of the various satellite operators.

SATCOM F2 (US domestic, 119 degrees west)

Transponder	Type of Video
4	Contract video, sports, and news
8	NBC pre-network feeds
10	Contract video, sports, and news
16	Contract video, sports, and news
18	Contract video, sports, and news
20	Contract video, sports, and news
22	Contract video, sports, and news
23	Alaskan Bush Terminal Video, half-transponder format

WESTAR I (US domestic, 99 degrees west)

Transponder	Type of Video
1	Contract video, sports, and news (networks)
2	Contract video, sports, and news (networks)
6	Contract video, sports, and news (networks)
8	PBS video (primarily eastern time zone)
9	PBS video (primarily central/mountain zones)
11	PBS video (primarily pacific time zone)
12	Contract and PBS video

WESTAR II (US domestic, 123.5 degrees west)

Transponder	Type of Video
1	WOR-TV, New York City (independent)
4	WGN-TV, Chicago (independent)
7	Spanish International Network (SIN) video, Mexico City
12	KTTV, Los Angeles (independent)

SATCOM F1 (US domestic, 135 degrees west)

Transponder	Type of Video
1	KTVU, San Francisco (independent)
2	PTL—Praise The Lord (religion)
3	WGN, Chicago (independent)
5	Star channel (east-coast and early west-coast feed)
6	WTCG, Atlanta (independent)
7	ESP (New England regional sports)
8	CBN—Christian Broadcasting Network (religion)
9	Madison Square Garden Events (sports)
10	Showtime (west-coast feed)
11	Warner Nickelodeon Children's Network
12	Showtime (east-coast feed)
13	KTBN—Trinity Broadcasting (Corona religious channel)
16	Fanfare (and shared feed for Holiday Inns of America)
17	WOR, New York (independent)
18	Reuters New Service
20	Modern Motion Picture Services, Penn State Sports
21	SPN (movies, sports)
22	HBO (west-coast feed)
23	HBO Family Channel ("Take Two")
24	HBO (east-coast feed)

ANIK III (Canadian domestic, 109 degrees west)

Transponder	Type of Video
4	CBC pre-network feeds, occasional use
8	CBC French-language television, 18 hours per day
10	CBC English-language television, 18 hours per day
12	CBC English television, northern TV service, 18 hours per day

and horizontal downlink. And they get away with this dual-polarization format inside the *same* 500-MHz bandwidth. By today's technology, this is just about the ultimate in frequency conservation since, in fact, two separate sets of signals manage to occupy the same spectrum at the same time, and they do so without interfering with one another!

Canada's domestic system (which was operational prior to the first US domestic satellites) fits the same operational format as the Western Union (WESTAR) birds. There are three of the Canadian ANIK birds with assigned orbital spots, although four have been launched. A recent (December, 1978) launch of ANIK-B is ultimately intended to be a replacement for one of the earlier ANIK-A-series birds. Although the Canadian system is run differently than the US system (the birds and their control stations are owned jointly by a government agency and by a consortium of Canadian telephone companies, operating under the trade name of TELESAT), it has the same technical operational characteristics as the US systems and will be described jointly with the US birds.

There are possibly three questions that might pop into your mind at this point. 1) Is it legal to set up a receiving terminal to access any or all of these satellites? 2) How much does it cost? 3) Where do I get the equipment or information necessary to build the equipment?

One question at a time. Is it legal? Yes, if you follow the proper guidelines established by the FCC or, in Canada, by the DOC. Basically, a geostationary satellite is nothing more than a common-carrier microwave relay station positioned in space. It is a broadband repeater not unlike the Bell or other microwave relay stations you see bundled atop nearby hilltops or tall buildings in your area. It is not a broadcasting station, like your local television station (although each is assigned call letters by the FCC), and the transmissions it relays are either privately owned or privately controlled. This means simply that under Section 605 of the Communications Act, you are not free to erect a station and receive the transmissions from a satellite *unless* you have obtained the permission of the owners of the programming material to access that material. The distinction here is that a satellite is a common-carrier relay station and its transmissions are not intended for the general public. They may ultimately be seen by the general public, but only after your local broadcasting station(s) or cable TV company have contracted with the owner of the program material to broadcast that material. This says, quite correctly, that the programming material on the birds is, by and large, privately owned while it is going through the satellite, and until you "buy a ticket of admission" you are not supposed to be enjoying it in your home.

There are thousands of backyard terminals now in operation or under con-

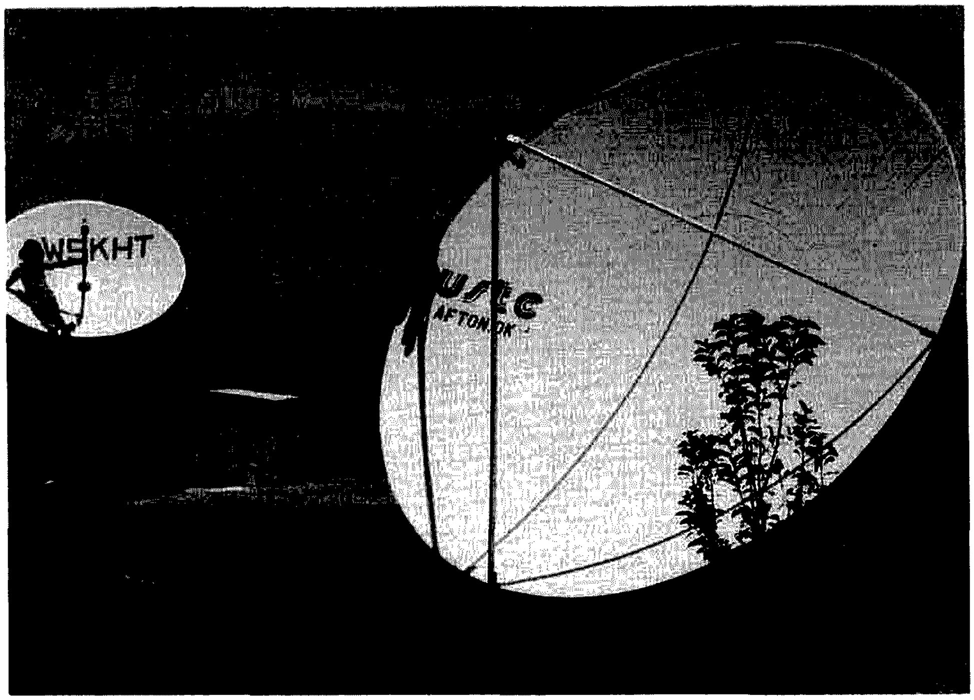

Photo G. Six-foot (left) and twenty-foot satellite antennas. The six-foot one is positioned on WESTAR I while the 20-foot one is on SATCOM F1. White reflective surface is essential to keep the sun's rays from "cooking" feed (and electronics there).

struction. Very few of these seem concerned about the legal requirement to obtain the permission of program owners before accessing the programs. Obtaining permission, at least from some of the program suppliers, is very simple, however. For example, the company that brings Atlanta WTCG and San Francisco KTVU up to the bird (Southern Satellite Systems) will grant a one-year use-right for an annual fee of $60 (per station). The religious channels (PTL, CBN, and KTBN) make such written grants without a fee. (I prepare a weekly program entitled *Satellite Magazine* which is distributed to the cable television industry on one of the satellites, and we routinely grant permission to access our program for no fee.) Table 1 summarizes current transponder usage.

Once you have written permission from a *single* program supplier, you then are able to complete FCC form 503, which is an application for an experimental radio receiving station license under Part 25. This one year, renewable license keeps you square with the FCC. The FCC is currently studying the possibility that satellite receiving terminals may not really need to be licensed after all, and perhaps before long, much of this paperwork will be a thing of the past.

How Much?

This is a tricky question because a great deal of the answer depends upon your own abilities, or the combined abilities of several people who agree to work together on the project. There are three essential elements to a TVRO (Television Receive-Only) terminal: the antenna, the antenna-mounted signal preamplifier (called an LNA, for low-noise amplifier), and the receiver itself. Fig. 6 shows the various parts of a typical satellite terminal. We'll look at each of these shortly.

When the first satellite programs for use by the cable television industry appeared in September, 1975, the terminals cost in excess of $100,000 each, installed. In those days, the FCC had a strange rule on the books which made it mandatory that a receive terminal utilize a receiving antenna with an aperture (diameter) of at least 9 meters. That translates to a parabolic dish antenna nearly 30 feet across—not something you would put in a normal backyard! Prior to the cable television industry's use of satellites for programming relay, the only intensive use of satellites was in the INTELSAT area. The big INTELSAT stations routinely cost several mega-bucks each, with receive antennas in the 50-100-foot class.

In December, 1976, acting on a petition that I drew up, the FCC removed the 9-meter restriction and began routinely to permit receive terminals as small as 4.3 meters (roughly 15 feet in diameter).

As a result of this change in FCC policy, the primary domestic industry utilizing satellites, the cable firms, has grown at an extremely rapid rate and is attracting all sorts of other industrial users of satellites. Back in December, 1976, there were but three channels or transponders in use for cable programming relay. By late spring, 1979, that number had grown to 20 on just one satellite, with another 4 to 6 on other satellites. The number of receive terminals installed by cable companies in operation in late 1976 was 75; now it is pushing 1,200 terminals and growing at a rate of nearly 100 per month.

A major motel chain (Holiday Inns of America) is currently installing the first of what will ultimately be perhaps 750 terminals. These motel terminals will be plugged into a special 14-18-hour per day satellite channel programmed with movies and sporting events available only at the affiliated Holiday Inns. Other major motel and hotel chains are expected to follow in short order. At least one national religious group (Full Gospel Businessmen International) initially will install around 350 terminals, which will be connected to local-service 100-Watt UHF translators operating in the UHF television band. Programming will be a mixture of the existing three religious programmed channels on SATCOM F1. And the surface is barely dented.

With volume production of satellite equipment now starting, the prices, not unexpectedly, are coming down. Cable firms are installing single-receiver 4.5-meter terminals for "as little as" $9,000 these days. And several hundred well-heeled individuals

have spent at least that much money to have their own backyard terminals.

Now, how cheaply can it be done? Taylor Howard W6HD of San Andreas, California, put his electrical engineering skills to work on the project at Stanford University where he is a professor. He ended up scrounging (in the best of amateur traditions) a 15-foot reflector surface and an azimuth-over-elevation mount from a surplus radar installation. Then he worked with some engineers at Hewlett-Packard, and, using the HP-6101-series bipolar transistors, he built a 2.8-to-3.0-dB LNA (low-noise amplifier) to mount at the feed of the antenna. Finally, for his receiver, he did some more scrounging and ended up with a surplus telephone company microwave communications receiver. Tay figures he may have $1,500 invested in the project, and his only real complaint is that his neighbors (when shown the pictures from HBO and other satellite programming sources) usually comment, "Yes, that's nice, but it's not any better than my Sacramento reception." People just don't have much appreciation for the technology!

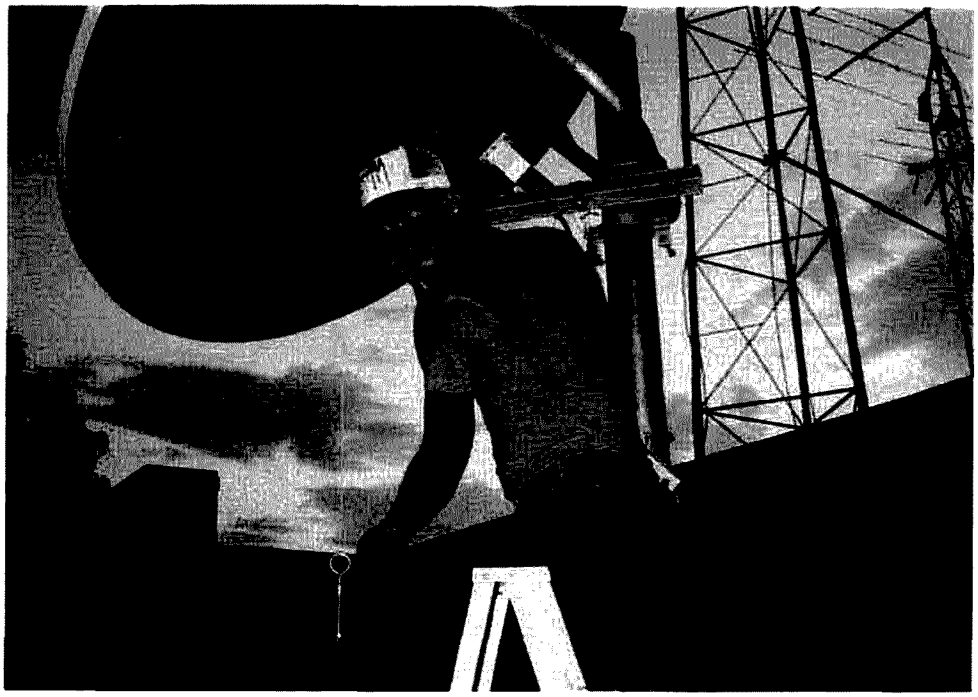

Photo H. The author checks the elevation angle on the six-foot satellite receive-terminal using a 29-cent protractor. The back of the dish presents a right angle to the feed, allowing use of a simple protractor with string and weight to check the elevation angle.

The quiet and steady development of backyard terminals by amateurs came into the full light of day this past October. In the October 21st edition of *TV Guide*, I had a short three-page article published which revealed just what a person could do in his own backyard. Thousands of telephone inquiries and letters later, a relatively clear pattern has evolved. There are apparently three types of enthusiasts out there.

1) Members of the *"I don't care what it costs"* group have socks filled with bucks and are willing to part with 12,000 or more of them to have a terminal installed by professionals. One energetic salesman for a major satellite terminal supplier took a stack of the October 21st *TV Guides* with him to Palm Springs and spent a weekend plying the country clubs. When he returned to his office the following Monday morning, he had ten checks in his pocket for $40,000 each, having sold that number of his firm's super-deluxe terminals simply on the strength of the *TV Guide* article!

2) Most people fall into the *"I don't have any money but I'd sure like one of those terminals"* crowd. Unfortunately, most of them also do not have any background which would equip them to sit down and assemble or construct the terminal on their own. Perhaps by 1983, or so, they will be able to walk into their neighborhood Radio Shack and buy such a terminal for around today's price of a TRS-80 computer. For now, they will simply have to sit and drool.

3) And, finally, there is the group that you probably fall into: the *"I don't have much money but I have a ham radio license and a background which should equip me to do most of this on my own"* set.

Of the three major elements in a satellite receive terminal, the antenna presents the best opportunity for individual effort. Some people will be fortunate enough to locate surplus or used dish (parabolic) antennas. A few of these may even come equipped with feeds for the 4-GHz range. But parabolic dishes are not that common, and the first wave of satellite TV enthusiasts has succeeded in driving up the prices and increasing their scarcity tenfold. Here are some parameters to watch out for.

1) The minimum dish diameter for most areas of the United States is ten feet. If you will look at Fig. 7, you will see an outline map of the United States and Canada with a set of "signal contours." For this particular satellite (RCA F1), if you are located within a 35-dBW or better contour, you can expect reasonably good reception with a ten-foot dish. In the 33- and 34-dBW contours, you will need a 12- to 15-footer. We'll come back to this.

2) The dish should have a design f/d (focal length to diameter ratio) in the .4 to .5 range. Most surplus parabolic surfaces will not have a feed attached and you will have to design your own (typically a simple horn antenna). Your feed should illuminate the total surface area and be 10-dB down at the edges of the dish surface. To simplify the design of the feed, the focal length should be in the range suggested.

3) The surface area need not be solid. The 4-GHz range is in the cross-over region where grid-wire or

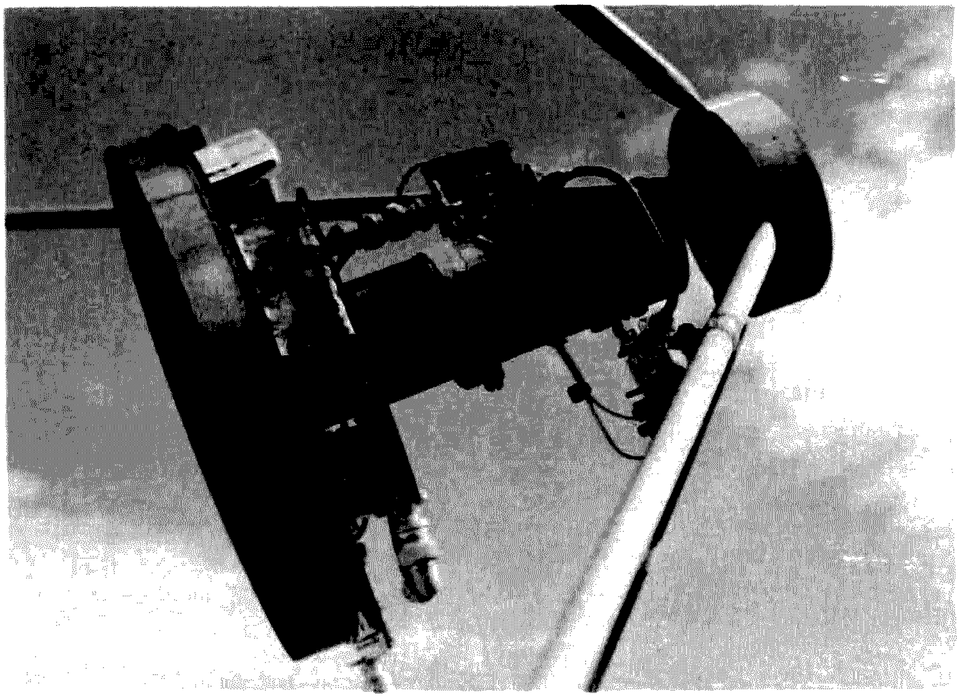

Photo I. G8AKQ's feed has two stages of low-noise amplification at the feed, with mixer, LO, and gain stages at his 450-950-MHz i-f also at the feed. The feed is a hybrid-mode scalar feed (corrugated horn) home-designed and built, allowing him to receive circular polarization from INTELSAT and Russian STATSIONAR satellites as well as linear-feed format birds.

fine-mesh reflector surfaces will work, but at reduced efficiency. Ideally, you will hope to have 55-58% efficiency from the antenna surface and feed combination to make the system operate properly.

You probably won't find a mount for the antenna, but if you do, the ideal mount is a polar mount system. Because there are numerous satellites in the sky, it is very handy to be able to install the antenna on a north-south (corrected) line and leave the elevation adjustment (i.e., up an down movement of the dish) alone, moving from bird to bird by swinging the antenna left or right (azimuth). This is what a polar mount does. The alternative to this is either an az-el (azimuth-over-elevation) mount or a fixed mount. Photo H shows an experimental six-foot antenna on a 4.5" fold-over pipe mount. The antenna is a terrestrial-style parabolic with a side-of-tower mounting kit which I have modified to allow manual elevation adjustment (a long support bolt that threads in and out to change the pitch, or elevation angle, of the dish). Azimuth adjustment is by the "armstrong" rotator method: You loosen some nuts and swing the antenna on the fixed pipe mount. A heavy prop-pitch motor could be rigged up to rotate the whole pipe just as well.

Another approach is simply to build the framework yourself and surface it with thin aluminum or galvanized steel sheet. One source[1] provides both plans and antenna kits for a 16-foot reflector surface, polar mount, and feed.

The antenna is the easiest place to make up system gain so that you can afford the luxury of less-sophisticated electronics. There is a very real trade-off possible between the noise figure (or noise temperature, as it is specified in these circles) of the LNA and the antenna gain. The satellite-to-Earth path is a long one with space losses in the 196-dB region. However, the long-term path loss varies less than ½ of one dB, so a receive-system designer can spend most of his time worrying about things like achieving an additional 1 or 2 dB of antenna gain, or lowering the LNA noise temperature by another 0.5 dB, with the expectation that such efforts will produce noticeable differences in his system.

The parameters of the system are shown in Fig. 2. It is an FM/FM system with 36-MHz-wide channels. Because it is FM video (and not AM video, as regular TV is) the system designer has the ability to take advantage of things such as the FM improvement factor and the "threshold" of noise. Getting the receive signal *above the threshold* is the key to high-quality reception, and slipping even half a dB below the threshold makes a big difference in the quality of the picture you see. For this reason, satellite terminal designers spend an inordinate amount of time looking for half-dB improvements, knowing that when they "make threshold" they are suddenly (and often dramatically, in terms of picture quality) "home free." The trade-off between LNA noise figure and antenna gain is summarized in Fig. 8.

All of this is another way of saying that, given an option, it is far better to build the antenna to achieve an extra couple of dB of raw signal gain than to assume that you can make up the difference (say between a 10-foot and a 16-foot antenna) with better quality electronics. This brings us to the electronics.

In the commercial area, virtually all LNAs are designed around mysterious little state-of-the-art devices called GaAs FET transistors. GaAs is short for gallium arsenide, a doping agent utilized in the manufacture of these very low noise, moderately high-gain transistors. Prior to GaAs FETs, if you wanted low-noise front ends at 4 GHz, you had to invest in parametric amplifiers priced upward from $20,000 each. With the advent of GaAs FETs, the cost of low-noise amplifiers "came down" to around $5,000 each for 2.5-dB-type noise figures at 4 GHz. More recently, 4-GHz preamplifiers have stabilized in the 1.5-dB noise-figure region at around $1,200 each.

Because of the very high losses in even 7/8-inch Heliax-type cable at 4 GHz (in the 3-dB region per 100 feet) and the extremely small signal margins (above the magic FM

threshold), the LNA is mounted directly at the feed of the antenna. Some experimental terminal designers, notably H. Paul Shuch N6TX, recommend that the LNA and the first downconversion stage (to a high i-f in the 1.2-GHz region) be located at the antenna feed.[2] A similar approach has been in use for two years by Steve Birkill G8AKQ, the world's foremost amateur experimenter in the satellite field. Ultimately, it is likely that many home terminals will be constructed in this fashion, but that is not fodder for this discussion. If the LNAs in use by the commercial folks are out of your price league, there is an alternate approach which hundreds of home terminals utilize.

Hewlett-Packard has an Applications Note (#967) which describes a single-stage amplifier producing around 10.5 to 11 dB of gain in the 2.6- to 2.8-dB noise figure region. By using two of their HXTR-6101 bipolar transistors, the circuit in the Application Note, and the board layout there, it is possible to achieve sufficient low-noise signal gain to drive perhaps 50 feet of 7/8-inch Heliax cable. To ensure that the noise figure of the HXTR-6101 LNA dominates the relatively high noise figure of the receiver (typically in the 11-14-dB region) it may be necessary to get into the 30-dB gain range with the LNA. Commercial units typically offer 50 dB of gain for this reason—as well as to allow for circuit aging.

This brings us to the receiver. Cable users first began buying receivers when they sold in the $10,000 to $12,000 range. More recently, a myriad of commercial receivers has appeared on the market including both tunable (i.e., covering all of the transponders) and single-channel (crystal-oscillator-controlled) models. Even with the stiffer competition and the market base broadening, satellite TV receivers remain expensive; the lowest-priced tunable units are in the $3,000 region, while the single-channel units are around $2,700. This is too high for most people.

The ultimate in low-cost receivers was assembled by a South Carolina amateur, Robert Coleman K4AWB. Robert has scrounged surplus equipment and assembled a fully operational home terminal for under $500. He even designed his own GaAs-FET LNA!

Another approach is the latest receiver designed by California's Taylor Howard. Starting out from scratch, Tay has created a widely duplicated receiver that tunes all 24 transponders, includes a bipolar LNA system, receives all of the audio subcarriers, and, using brand new parts from commonly available parts sources, can be copied for under $1,000 per "radio." Plans for both the Howard Terminal and Coleman (TD-2) Conversion terminal are available.[3]

Some home-brew terminal builders have taken advantage of one possibility by scrounging around for a Bell microwave TD-2 (video) receiver. Recall that (Bell) terrestrial microwave systems occupy the same 3.7- to 4.2-GHz range as the satellite downlink signals. With some work, these receivers can be made to function in this service. Other than sitting down and designing your own 4-GHz-to-baseband receiver, there are two other possibilities. Microcomm (H. Paul Shuch N6TX) has a series of modules which, when combined, make up a 4-GHz to 70-MHz i-f system in two downconversion steps. This particular system, if you elect to use all Microcomm modules, includes a

*Most US and Canadian domestic satellites transmit the accompanying audio on a 6.8-MHz FM aural subcarrier. However, certain of the WESTAR (Western Union) users prefer to utilize a 6.2-MHz FM aural subcarrier. Thus, a receiving system for "all possible" signals must be equipped for either subcarrier audio.

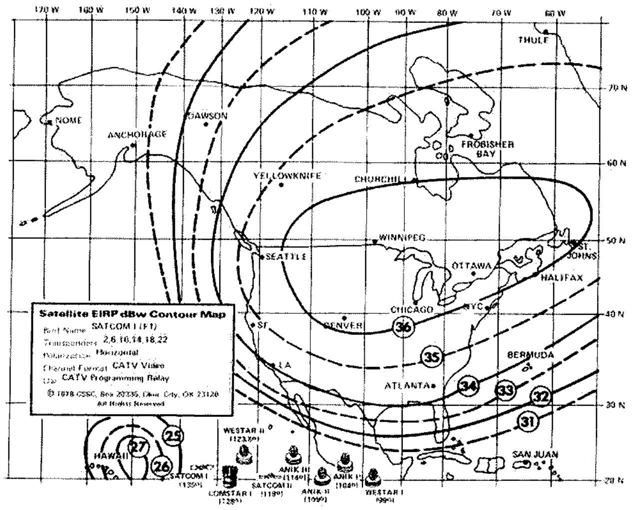

Fig. 7. This EIRP map illustrates the effect of carefully engineered "sculptured antenna radiation patterns" on the ground level signals from a satellite. WESTAR and ANIK-series satellites have a single pattern for all 12 channels, while SATCOM and COMSTAR satellites have four different patterns per satellite with six transponder channels grouped to a single transmit antenna (four such antennas per bird). Signal contours are in dBW (decibels above one Watt) nomenclature, with progressive circles in 1-dBW steps.

For An EIRP Area Of 36 dBW*

Antenna Diameter (60% efficiency)	Antenna gain	LNA noise figure	Video signal to noise ratio
6 foot (1.8 meters)	36 dB	1.0 dB	48 dB
8 foot (2.4 meters)	38 dB	1.7 dB	48 dB
10 foot (3.0 meters)	40 dB	2.6 dB	48 dB
12 foot (3.7 meters)	42 dB	3.8 dB	48 dB
15 foot (4.5 meters)	44 dB	5.1 dB	48 dB
20 foot (6.0 meters)	46 dB	6.6 dB	48 dB
30 foot (9.2 meters)	49 dB	9.2 dB	48 dB

***These numbers assume a 27-MHz i-f bandwidth, which creates an improvement over a full 36-MHz-wide bandwidth of approximately 1.3 dB without sacrificing baseband video picture quality.**

Fig. 8. Private receive terminal parameters. To determine (with 95% or better accuracy) the type of results you can expect with various match-ups in antenna size, LNA noise figure, and receiver i-f bandwidths, these numbers are useful. Note that you must first determine the EIRP in your area using EIRP maps available for this purpose.

Photo J. Six-foot antenna pictures from WESTAR I. This picture exhibits noise (known in the trade as "sparklies"); LNA in use when the picture was taken was a 1.5-dB noise level unit, about 0.5 dB too "high" for noise-free pictures.

24-dB-gain LNA built around the HXTR-6101 bipolar transistors, and when this is considered, the $1,700 price tag for the complete set of modules (wired and tested) may be cost-effective to some terminal builders. For individuals interested in the Microcomm approach, an applications note is available.[2]

The final approach at this time is to carefully study how the existing commercial receivers are designed and select the best of the various circuits to suit your own capabilities and pocketbook. A "Satellite Study Package" prepared to assist people in making a decision on the best way to go for your location is available.[4]

The Road Ahead

Having piqued your curiosity regarding satellite television terminals just a tad, some practical suggestions on what to do next might be in order.

There are only two things which usually create substantially lower equipment pricing. One is technological breakthrough and the other is very high volume production. Let's talk about both.

Back in 1971, a group at Stanford University studied the Earth terminal design vs. pricing conflict. They had a NASA contract which was part of a then-current proposal to launch a geostationary satellite to provide television reception to rural areas of Brazil. The group came to the conclusion (and developed the hardware to substantiate it) that with the 2.6-GHz satellite proposed, they could produce seven-foot parabolic antennas with feed, LNA, and receivers for well under a $200 material and labor cost per terminal, in 100,000-terminals-per-annum quantities. Brazil never bought the NASA proposed package, so the proposal more or less died.

More recently, the Japanese launched an experimental satellite called BSE. This one operates in the 12-GHz range, and to support the program (which is providing a channel of color television to all of Japan and Okinawa), the Japanese electronics industry has produced a small quantity (around 200) of experimental terminals. The Japanese have calculated the cost of the terminals in annualized quantities of 10,000, and they come to the conclusion that they could be built for a market cost of under $300 each.

So why do our terminals cost so much?

Two reasons, and they interrelate. In the Stanford study for NASA, a relatively low frequency for the downlink was assumed: 2.6 GHz. If you are rock-bound on 80 meters, 2,600 MHz may seem very exotic to you, but it is sufficiently low in the microwave spectrum so that exotic and expensive components such as GaAs FETs are not required for system design. The ability to use a $1.00 transistor in the front end versus having to use a $125 (GaAs FET) transistor is very important indeed!

In both the Stanford NASA study for Brazil and the existing Japanese BSE experimental bird program, the designers purposefully built a considerable amount of transmitter power into the bird itself—a subject we've not discussed up to this point. With the exception of the new ANIK-B satellite, the signals that wing their way through around 196 dB of space loss start out at the 5-Watt peak-power level. This output level (+7 dBW) plus the gain of the downlink transmitting antennas (28-29 dB in the center of the pattern) result in the EIRP pattern shown in Fig. 7: +36 dBW in the center or boresight of the antenna pattern. The Japanese BSE manages to start out with 200 Watts of transmitter power, and when that is coupled with its transmit antenna gain, the boresight (center) of the EIRP pattern is +55.5 dBW. That makes it around 20-dB hotter on the ground than our domestic satellites (and as much as 33.5-dB hotter than G8AKQ's INTELSAT signals which he receives in Sheffield, England!). On the surface, that translates to far simpler receivers, even when you add in the additional "free-space loss" that occurs at 12 GHz as compared to the 4-GHz downlink of the present domestic birds.

On top of that, you must remember that for a given size of parabolic reflector surface, each time the frequency is doubled the gain goes up 6 dB. On the receive end of the circuit, if you have 20 dB more signal at the antenna (because of the more powerful satellite signal) *and* antenna gain is 9 dB higher for a reflector surface of a comparable size than the same reflector would be at 4 GHz, some things can give. In the BSE experiment, two things "gave." First, they threw out the LNA and went directly into special diode mixers with noise figures in the 7-dB region. Then the BSE engineers reduced the size of the receive antenna (reflector surface) so that they had just enough antenna to provide a margin for system aging and some additional weather-effect losses that start to be troublesome in this frequency range. The net result is that 6-foot (1.83 meter) antennas, no LNA, and relatively simple single-channel receivers are practical with the BSE program. With these kinds of changes from our present domestic satellite system parameters, it is little wonder that the Japanese can bring the production costs down to the $300 range. Perhaps it is a wonder that it is so high!

As noted, space loss (from the bird to you) increases with frequency. While antenna gain goes up, LNA technology becomes more difficult with an increase in frequency and that translates to more expense. Fortunately, per-

haps, there is *no* need for LNAs at that frequency range. The receiver design stays about the same in either case, being more dependent upon frequency agility than input frequency.

Direct broadcasting satellites are something of a political problem. Regardless of who owns and operates them (i.e., government or private industry), there are many opposing forces pulling and tugging at the prospect of their operating in the United States. This leaves us coming to some logical conclusions about the next five years or more in the world of North-American satellite communications.

What You Can See

Commercially-constructed satellite terminals for the present 4-GHz band (although also perhaps for services not yet dreamed of) will proliferate. Battle lines already are forming to tighten satellite-to-satellite spacings in the orbit belt; present regulations require 4- to 5-degree spacing between birds operating on the same downlink band. RCA will have a shot at a 3-degree spacing late this year, and if that works, there will be room for perhaps six additional satellites serving North America. Experience has proven that with 4-degree spacing, when your 15-foot or larger antenna is pointed at one satellite, the interference from adjacent satellites cannot be detected on the television screen. It is there, but it is down so far in amplitude as not to be noticeable.

The American appetite for multiple channels of service will keep our future satellites multi-channeled. Having proven that 24 channels can be crowded into the spectrum space originally allocated to 12 channels through the use of dual polarization, future satellites will follow this format. Spectrum use (or maximum use of the spectrum) is a very important ingredient in space communications.

However, as long as it takes approximately as much solar power and battery reserve to operate one 200-Watt single-channel satellite (i.e., BSE) as it takes to operate twenty-four 5-Watt satellite channels, and additional solar power comes only at the expense of larger solar panels which come at the expense of larger rocket or Space Shuttle payloads, it is unlikely that short-term future American domestic satellites will go up in transmitter power much beyond their present limits. The recently launched ANIK-B has twelve channels with 10-Watt peak power aboard per channel, which results in Earth terminal antenna sizes within the boresight decreasing by the same 3 dB (or LNA noise figures going up approximately 3 dB); but that is for 12, not 24, channels. For the Canadians, having 3 dB more signal on the ground is more important to their space communications program than having another 12 channels of transponders available. Unlike the Americans, the *Canadians* have space spectrum to spare.

All of which suggests that, at least through 1985, it is unlikely that very many of the domestic satellite communications channels will be coming downward with very much more ground level signal than we now have available. Clearly, if advances are to be made in reducing the cost of the Earth terminals, it will have to be as the result of creative ground-station engineering. Much higher satellite powers are not likely for us in the foreseeable future. And that says, for all of the kitchen-table-building amateurs out there, that here is the type of frontier which fascinated the amateurs of the 20s and early 30s. The challenge of the 80s is in space communications.

The nitty-gritty of the challenge has been outlined for you here. Now, get out your tin snips, your micrometer, and your microwave diodes and go to work. Hundreds—no, thousands—are already at work on this project. A handful will make significant contributions to microwave state-of-the-art. A few will become wealthy beyond their wildest dreams. And everyone will become a part of the most fascinating television programming ever radiated from a transmitting antenna in or out of this planet we call Earth. ■

Photo K. Private terminal receiver designed initially for Canadian "backwoods terminals" features continuous tuning dial, tuning meter (with afc on and off switch), and selectable aural subcarriers. Unit (PT-1024) is manufactured by Satco, in Lewisville, Texas.

1. A 16-foot parabolic antenna designed specifically for the private experimental terminal user is available in either kit form or as a do-it-yourself project from a comprehensive set of plans from Paraframe, 611 Farmview Road, Park Forest South IL 60466.

2. An 8-page application note (#3), describing satellite TV terminal receive-system design parameters utilizing pre-wired and tested modules, is available for $1.00 plus an SASE from Microcomm, 14908 Sandy Lane, San Jose CA 95124.

3. The *Howard Terminal Manual*, describing complete construction of a state-of-the-art TVRO receiving system with LNA, and a 24-channel tunable receiver, is available; it includes complete schematics, board layouts where required, and part sourcing. The *Coleman TD-2 Conversion Manual* describes conversion of surplus equipment to TVRO reception service, plus details of the layout and construction of state-of-the-art GaAs-FET low-noise amplifiers for 3.7 to 4.2 GHz. Each manual is $30 alone, or both together are $50, from Satellite Television Technology, PO Box G, Arcadia OK 73007; (405) 396-2574.

4. A foundation in the world of geostationary (TV relaying) satellites can be acquired through the "Satellite Study Package." Included is a 72-page booklet describing the full satellite TV system, programming sources, typical system layout, and many references. Also included is a 22 x 35 four-color, two-sided "Satellite Wallchart" which details the operation of more than 30 geostationary satellites. The price is $13 US ($16 Canada) from Satellite Television Technology, PO Box G, Arcadia OK 73007.

A Three-Digit Timer for TTL Illiterates

—c'mon, tube fans, give it a try

Ken Henry K3VTQ
RD #1
Hopewell PA 16650

Since the publication of my article on the 10-minute ID timer in the May, 1977, issue of *73*, I have had some requests for a three-digit timer, as well as some embarrassing feedback because I neglected to show the power connections for the 7448 and 7400 ICs. (7448 IC pin 16 goes to +5 volts, 7400 IC pin 7 goes to ground, and pin 14 goes to +5 volts.)

A three-digit timer requires only two more LED readouts, two more 7448 ICs, 16 more 220-Ohm resistors, and one 7400 IC. The counters are already there, but need to be connected in another fashion.

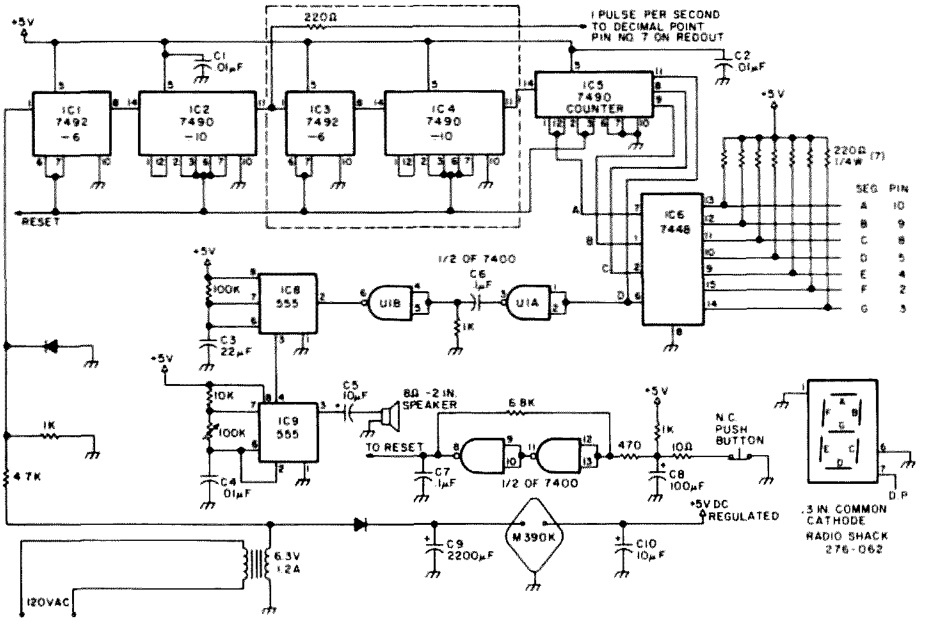

Fig. 1. The area which has to be changed lies within the dotted line.

Fig. 1 shows the area within the dotted line that has to be changed. The blinking decimal line is not used; IC3 and IC4 exchange places and are wired as shown in Fig. 2. The LED readouts have right-hand decimal points and, by inverting the middle digit, a colon is formed between the minutes and seconds digits. These decimal points are wired separately through individual 220-Ohm resistors to +5 volts. The segment hookup has to be reassigned for the middle digit. I will not describe this process, as you may possibly use another type of LED readout. This concludes the information needed to wire

the three-digit timer. I prototyped one, and another ham built a working model for his station console using larger readouts. I have not converted my timer, however. I am waiting for some ambitious cat to come up with a drilled PC board for the three-digit model.

I did not know how to reset that middle digit at the end of 60 seconds, so the following is an adventurous safari into the unknown. My first unfruitful attack was researching my old magazine issues for a cut-and-dried circuit to do the resetting job. This takes a lot of time because I found some neat projects and started to check the junk box. I could not find what I wanted, however; life isn't that long. Then the power of reasoning was tried. We know the counters are held low to count and made high to reset to zero. We needed a circuit that would reset the middle digit to zero at the end of six counts and we also wanted to manually reset the counters at any time.

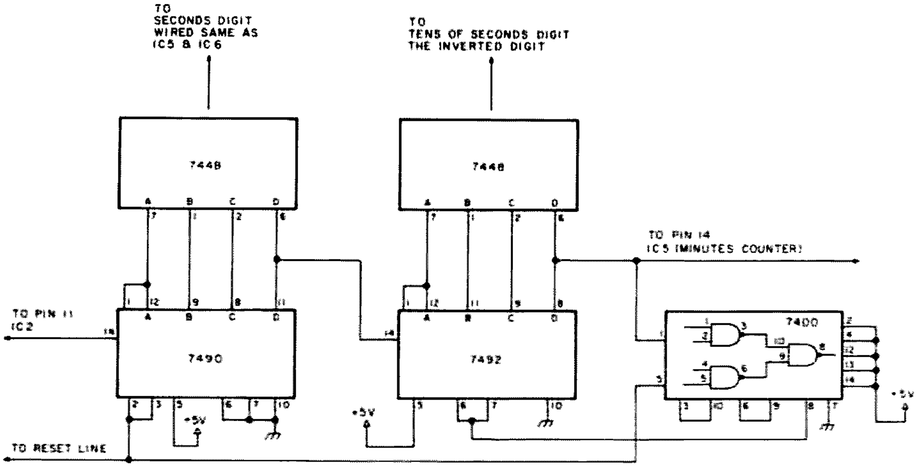

Fig. 2. Automatic reset of tens-of-seconds digit at end of 60-second count.

An examination of the truth tables in Fig. 3 shows that the 7492 was the ideal choice, as the "D" output goes high at the end of six counts and could be used for the high we needed to reset the counter. *The TTL Cookbook*, page 83, describing the 7492, stated, "The counter may be reset to zero by bringing either or both "0" set inputs positive." (These reset pins are #6 and #7.) Boy! This is going to be easier than I had hoped. All I needed to do was wire one reset pin to the "D" output and the other reset pin to the manual reset line. This first failure left me rather numb for some time. It took a long time to convince myself that there was a misprint in Don Lancaster's famous *TTL Cookbook*. My next source was the *TTL Data Book* by Texas Instruments. Fig. 3(d) shows the 7492 reset/count function table. It plainly shows that both reset pins must be made high to reset to zero.

The average TTL illiterate would have given up by now, but not this one. What was needed was a little black box with two inputs and one output so designed that a high on either or both inputs would give a high output to reset the timer; also, when both inputs are low, the output must be low to hold the reset low in order to count. This sounded a bit familiar and is described on page 128 of *The TTL Cookbook* as the OR gate. The truth table of the OR gate is shown in Fig. 3(a) and is exactly what I had been looking for. I am getting picky now, but I found another mistake on the same page. A NOR gate symbol is shown instead of the OR gate. The OR gate is not stocked here, so I used ¼ of the 7400 as shown on that same page, to custom-make the OR gate.

The purpose of this article is to illustrate to the novice and diehard tube addict who has never wired a transistor that they can have a ball playing with ICs. Almost all of my projects are one-shot deals, so I use the direct wiring method on .1" vectorboard for the projects I intend to keep. This is confusing when you turn the board over to do the wiring. Some people have been known to wire the wrong IC backwards. Wiring from a schematic is always a hassle, as the designer puts the pins anywhere for ease of drawing. It is much easier if you place a piece of carbon paper with the carbon side up under a plain piece of paper. Draw in all the components on the side just as they will be placed in your vectorboard. There is a tendency to crowd things, but this should be avoided.

I use sockets for all the ICs, as it makes for easier troubleshooting. It is nice to be able to try other ICs if a project fails, just to prove to yourself that you made a wiring error. Draw in all the wiring and make an over-sized period at every solder connection. When the working diagram is completed, turn it over and you are all set to go (if you had the carbon paper turned the proper way). Stick the components in the board, bending pins here and there to hold them in place. Heat up the old soldering iron and you are on your way to becoming a TTL addict. ■

Sound for the CMOS Logic Probe

—keeps your eyes on your work

As mentioned in my previous article, "Ultra-Simple CMOS Logic Probe,"* sound can be added either in addition to the LED lamps or instead of any visual signal. This article describes a circuit which adds the sound option, and provides a design which meets the same criterion as the design for the logic probe: inexpensive implementation. A way devised to use a single 555 timer in its astable mode to produce three different tones. These tones are then amplified with a single op amp and fed to a speaker.

*Mark Forbes, "Ultra-Simple CMOS Logic Probe," *73 Magazine*, June, 1979, p. 50.

Operation

The operation of the audio circuit is really quite simple, although perhaps unique. As shown in the schematic, the use of the 4049 buffers must be included in the logic probe. These provide the necessary drive for the 555. The 555 is shown in the familiar astable configuration with one modification: Instead of pulling pin 7 to Vcc through a single resistor, three resistors are used in series and are driven high by the 4049s. The 1N914 diodes provide isolation. Since the time constant is directly related to the pull-up resistor, increasing the resistance lowers the frequency of the audio tone.

When no signal is present on the probe tip, the oscillator does not operate. When a low is present, the 6.8k resistor is effectively tied to Vcc, and a low frequency tone is heard. If a high is detected, an additional 3.3k is added and the diodes act in an OR gate fashion so that the path is from the HI inverter, through both resistors, to pin 7. A pulse signal acts similarly. It should be noted that a high overrides a low, and a pulse will override either. Therefore, if a pulse is detected, the corresponding tone will be heard even if a high or a low is already present.

From the 555, the signal is amplified by an LM386 audio amplifier. A high-low volume switch is provided to allow the volume to suit the conditions. The circuit will work at a reduced volume if the 555 is fed directly through a 27-Ohm resistor to a speaker. However, the LM386 is recommended.

Construction

My version of the audible logic probe was built on a Vero DIP prototyping board. This allowed easy placement of parts, and made the board narrower by eliminating circuit board foils. A circuit board could be made fairly easily if the builder so desired. The 555 and LM386 seem to be relatively immune to extraneous oscillations, so parts placement is not too critical.

Conclusion

After building and using the audible logic probe, I found a marked preference for this type over the visual type. First, the probe can be made quite thin and small since all the control circuitry can be housed remotely. Secondly, the audible tones allow the operator to keep his vision fixed on the circuit under test; he will not have to look at the lights. The addition of this device requires only a handful of parts; it is quite worthwhile. ■

External Relay Control for Converted CBs

—switch anything with this setup

A simple accessory with many uses.

You can pick up new CB transceivers for very little cash. It's really not a difficult job to put these on the amateur 10 meter band. There's just one little catch: Very few CB transceivers have means of controlling external circuits. We radio amateurs, however, are accustomed to having means in our exciters for the control of external devices. This article describes a simple, easily constructed accessory that provides the missing control function.

Really, the circuit is just a third of a larger project, one that will use a CB SSB transceiver for operation on one of the Air Force MARS frequencies that lie far removed from any amateur frequency band and therefore require something other than the common amateur transceiver for operation. That project will be treated later.

For now, let's consider just what's needed to provide that control function. First, we'll need some means of sensing the rf generated by the transceiver when it's activated to the transmit mode. An isolating resistor backed up by a capacitor for further isolation, an rf choke for a return dc circuit, a signal-type diode, and a bypass capacitor take ample care of that job. Now the rf signal has been transliterated into a dc form, a form suited for actuating a transistor amplifier.

Although it might be feasible to use a single transistor to control a suitable relay, a pair of transistors connected as a two-stage dc amplifier can use readily-available components, ones you can pick up at Radio Shack or, better still, salvage off a surplus computer board. Such an amplifier can provide sufficient current to actuate a multi-pole, double-throw relay. Finding such a relay may not be an easy task. I was fortunate, as my junk box yielded several General Electric Company model CR2791 B100J3 relays. These are three-pole, double-throw relays that snap over firmly at a current flow well within the capability of run-of-the-mill transistors.

With the components identified, let's take a look at the circuit. You'll note that it's one well-adapted for laying out on a printed circuit board. For the prototype, I used a Radio Shack model 276-1392 perfboard and flea clips. This board also had the unexpected advantage of having suitable hole spacing for mounting the G.E. relay!

The values of the several components were arrived at by experimentation. In most cases, considerable latitude is permissible. For instance, R1 was varied from 500 Ohms to 5000 Ohms with no discernible effect upon circuit operation. The two .005-uF bypass capacitors may be replaced by any ones having low reactance at 27 MHz. Similarly, the rf choke was shifted from 45 microhenries to 2 millihenries with no undesirable effect.

A number of NPN transistors were tried. Most worked. A 2N335 was left

in the circuit solely because it was the last of a satisfactory series tested. The PNP is a bit more critical. It has to develop sufficient collector current to snap over a relay and hold it over for a considerable period. Therefore, it needs to be husky as well as being easily turned on. A number fell within this category. The 2N1381 does an excellent job, as do the Radio Shack HEP S5013 and HEP S0012. The one left in position was unmarked and was salvaged off a computer board.

Needless to say, the signal-type diode is highly uncritical. Just about any one will work and work well.

The 1000-microfarad capacitor across the relay coil may be omitted if you don't intend to use the unit with an SSB transceiver. Its function is to hold the relay actuated between spoken words. In the prototype, that particular value provided the desired delay. You may have to experiment to get the delay you want.

Now, let's talk about how the thing works! A signal is piped in through the R1C1 isolating (and power-reducing) combination to CR1, where it is rectified. The resultant dc circulates through the CR1-Ch1-C2-emitter/base junction mesh to trigger off TR1. Current then flows from the negative terminal of the power supply through TR1 through R2 to the positive power supply terminal. That resistor serves to limit the collector current of TR1 and should not be reduced appreciably in magnitude. The IR drop across R2 is applied through R3 (another current-limiting resistor) to the base of TR2, with C3 serving to bypass any residual radio-frequency component of the signal. That transistor (TR2) is inverted, having its emitter to the positive power supply lead. Its collector load consists solely of the dc resistance of the relay; therefore, a relay of at least 200-Ohms resistance should be used in order to limit the collector current to a tolerable figure. As mentioned earlier, capacitor C4 is used only to hold the relay contacts closed during the short pauses in SSB speech.

With the use of a multipole relay, a variety of control functions can be had. You may want to bypass an amplifier, turn off a power supply, or . . . you name it!

Build this unit. It's fun to build, and it has many uses. ■

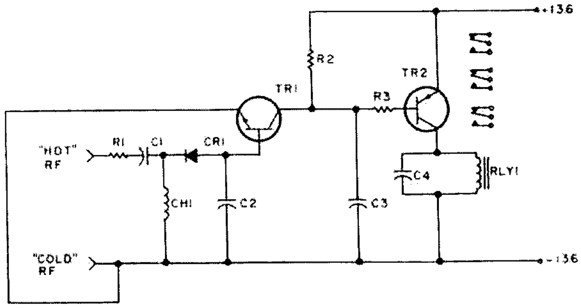

Fig. 1. Rf-actuated control unit. C1—47 pF. C2, C3—.005 uF. C4—1000 uF. R1—5000 Ohms. R2—2200 Ohms. R3—1000 Ohms. CH1—56 uH. CR1—signal diode. RLY1—General Electric CR2791 B100J3. TR1—2N335. TR2—2N1381. R1 is adequate for 4 Watts carried in a 52-Ohm cable; adjust for other powers or impedances. All resistors are ½-Watt. C1, C2, and C3 are mica. C4 is rated at 16 volts.

Preserve Your Sanity with this Midland 509 Mod

—why put up with rotten noises?

Wayne Rankin WA6MPG
PO Box 41
Tujunga CA 91042

The Midland 13-509 is basically a nice radio. It does, however, have a few areas where there is room for improvement. One of the most obvious shortcomings of the 509 is the squelch circuit. It has been properly accused of a rather sharp attack, and a blast of noise when you let go of the mic button that becomes old after the second or third transmission.

There is a rather simple cure for these problems, and all it will cost you is a resistor, a diode, and about ten minutes of your time.

Fig. 1 shows the squelch circuit of the 509. The addition of a diode connected in series with a resistor from a keyed 12-V dc bus will keep the squelch switching transistor (TR-13) closed during the transmit period. This will eliminate the irritating blast of noise that was caused by the squelch circuit suddenly being energized at the release of the mic push-to-talk button.

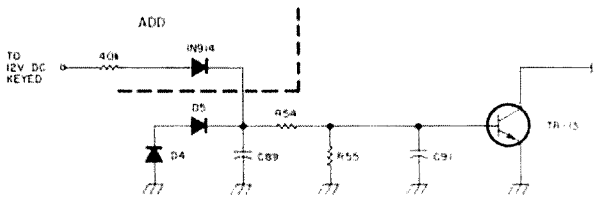

Fig. 1.

This modification also will broaden out the squelch action, which may or may not be desirable, depending on personal preference. If a harder squelch action is desired, cut C91 out of the base circuit of TR-13. This capacitor does nothing but delay the lockup of the transistor.

Placement of the parts is not very important, but take care that these new components do not short out anything in the adjacent circuitry. The +12 V dc may easily be obtained from pin 3 of the accessory jack at the rear of the radio. If a more sanitary approach is desired, I suggest point 27, near the speaker on the transmit board. I have used both points with equal results.

The slender lead of the 914 diode will probably slip right into the hole in the PC board, allowing installation from the top. If this method is not practical, attach the diode to the bottom of the board. Be sure that you have located the correct place for the connection, as all of that foil down there tends to look the same.

My experience has been that a small, slightly-obnoxious noise, frequently repeated, will become extremely irritating over even a short period of time. Think of this as you find yourself strangely enraged after what should have been a pleasant QSO in your mobile. Was it the weather, the traffic, or the "squelch tail" on your radio?

Modify your squelch and have a nicer day! ■

Touchtoning Your Memorizer

—Yaesu's made it easy

Tom Hart AD1B
730 Gay St.
Westwood MA 02090

I recently purchased a Yaesu Memorizer for my two meter operations. This has been my first exposure to synthesized operations, and I've been very surprised at the amount of activity that I can hear while listening up and down the band. All in all, the Memorizer is an excellent buy and meets all of my expectations.

Fig. 1. Front view of Yaesu connector.

Since touchtone™ facilities come in very handy at times, I decided to look into using my Drake touchtone mike (model 1525EM) with the rig. The Yaesu manual does not give any data on the microphone requirements, so I checked the schematic. It appeared that the rig is factory-wired to provide 12 V dc at the mike connector. A check with a VOM showed that pin #4 does provide the voltage necessary for the pad and that no internal modifications would be required. I rewired the Drake microphone with a Yaesu connector as shown in Fig. 1.

The new arrangement works quite well and no adjustments were necessary to the tone levels. It worked on the first try. What's more, the new mike caused no loss to the audio qualities of my golden tones while in the windbag mode. So, if you want to use a touchtone pad with your Memorizer, this arrangement will work quite well. ■

The Small But Mighty Arboreal Aerial

—tree-hanging triband vertical

Living in apartments these past five years, I've learned a lot about short antennas, bent antennas, and antennas with traps. I've had to. I simply haven't had the room to put up the kinds of antennas that I would really like to have. Fortunately, I've usually had a small patch of dirt and a sturdy tree outside the window. By stringing up, over the years, an assortment of temporary wire antennas running to the nearest tree limb, I have been able to make many good contacts on all bands from 160 meters to 2 meters. And I've done my DXing with low power to minimize TVI and CQs coming out of the speakers of neighbors' stereos.

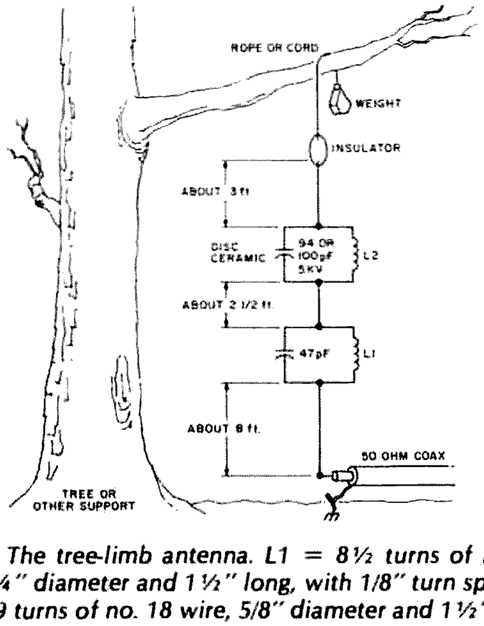

Fig. 1. The tree-limb antenna. L1 = 8½ turns of no. 18 wire, ¼" diameter and 1½" long, with 1/8" turn spacing. L2 = 9 turns of no. 18 wire, 5/8" diameter and 1½" long, with 1/8" turn spacing.

An efficient three-band vertical for power levels under 200 Watts can be made cheaply with wire, insulators, and homemade traps. The wire vertical that I've used for more than two years can be suspended from a tree limb or other support. It can be bent, sloped at angles up to 45 degrees or more, used indoors, rolled up and taken on camping trips, or tossed out an upstairs window to work as an "inverted vertical." Some sort of ground system is necessary, and a network of radial wires beneath the vertical could make it perform as well as a store-bought trap vertical.

You also can make two of these wire antennas for 20, 15, and 10, hook them to coaxial cable in the usual dipole fashion, and have a dandy three-band antenna for horizontal or vertical mounting.

A grid-dip oscillator is necessary to adjust the traps to the right frequency range. To protect the traps from rain and ice, I enclosed them inside plastic film canisters that come with Kodak 35mm film. Punch holes in the lid and the bottom just big enough to pass the ends of the wire. The holes and film canisters will be sealed later with glue or varnish, after the traps are installed.

Begin by cutting a piece of antenna wire to a length of 8 feet 6 inches. Connect one end of this wire to your coax and ground system. Suspend the other end vertically from an insulator and a support. Using your swr bridge as a guide and a few Watts of 28-MHz rf, trim the antenna from the top—a half inch at a time—for the lowest swr in your favorite section of the 10-meter band.

Take down the wire temporarily and build the first trap. I used a 47-pF, 5-kV disc ceramic capacitor hooked across 8½ turns of no. 18 wire, ¼ of an inch in diameter and 1½ inches long, with the turns spaced by 1/8 of an inch. Do not solder the leads together until you have trimmed the coil to resonance at 28

MHz using the grid-dip meter. Then install the trap in its case and solder one lead to the top of the wire previously trimmed for lowest swr on 10 meters. Solder a 3-foot piece of antenna wire to the top lead of the trap, suspend this combination from a support, and trim the top section for lowest swr on either 21 MHz or your favorite section of the 15-meter band. On my antenna, this top section turned out to be 2½ feet long.

If you want only a 15- and 10-meter trap vertical, you can stop right here and put the antenna up in the air. But if you add just one more trap resonant to 21 MHz and another 3 feet of antenna wire, you can operate 20 meters as well. My second trap consists of two 47-pF, 5-kV disc ceramics in parallel (94 pF total capacity—or use 100 pF) hooked across 9 turns of no. 18 wire, 5/8 of an inch in diameter, 1½ inches long, with the turns spaced by 1/8 of an inch.

Using the grid-dip meter, trim the coil and capacitor combination to resonate at 21 MHz. Then solder the trap to the top of the wire previously trimmed for lowest swr at 21 MHz. Solder 3 feet of antenna wire to the top of the trap and trim the wire for lowest swr on 14 MHz.

Hang the wire securely from a tree limb or other support and put it on the air. The whole antenna is about 14 feet long.

I don't make any great DX claims for this antenna, but it has helped me reach all continents with 180 Watts or less. And I haven't had to give up ham radio just because I live in an apartment.■

What Do You Do When Your Rotator Dies?

—you fix it . . . like this

Carl C. Drumeller W5JJ
5824 NW 58 St.
Warr Acres OK 73122

The Problem: After several decades of faithful service, the control unit of my Ham-M rotator ceased functioning. A postmortem examination revealed a dead 130-microfarad, 50-volt alternating-current motor-starting capacitor.

The Non-Solution: A quick survey of electronic supply stores showed that no such capacitors were available. A visit to electrical supply houses revealed numerous motor-starting capacitors, but none was physically small enough to fit into the space within the control unit housing.

The Solution: Two 150-microfarad, 50-volt electrolytic capacitors and two 100-volt, 3-Ampere silicon rectifiers were used in the circuit shown. The control unit was resuscitated.

Another interesting situation came to light during the repair job. The meter had been intermittent, sometimes operating normally, sometimes quite dead. The cause was the 1/16-Ampere fuse used in series with it. This is indeed unusual. A fuse normally is fully conductive or unmistakably open. This one probably had a mechanical discontinuity instead of having been blown. The original one was soldered in place, an action fraught with peril to the delicate interior conductor. A clip-type fuse holder was installed to minimize the probability of future trouble.

For those interested in the theory of the functioning of the circuit, the explanation is simple. During any half-cycle, one capacitor is shorted by its associated diode. It might be presumed that having two capacitors in series, the resultant capacitance would be halved. This, however, is not the case because the diode acts as a bypass for the capacitor during every half-cycle. ■

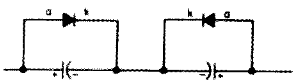

Fig. 1.

Beams vs. Linears: Which Should You Buy First?

—get the most bang for your buck

John O. Battle N4OE
4612 Broadmeadow
Huntsville AL 35810

Many hams who would enjoy the performance and convenience of a rotary beam antenna hesitate to consider this alternative because of the cost. Instead, they purchase a linear amplifier with hopes of making up for the lost antenna gain with power. This is not only a less desirable solution from the standpoint of "spectrum pollution," but it also results in less performance and more dollars spent, making it a poor choice indeed. Why? Read on.

First, consider the average amateur installation prior to purchasing either a beam or a linear. The transmitter input power is about 180 Watts, and the antenna is a trap vertical. The effective radiated power on twenty meters is given by: $P_{erp} = (P_t)(\eta_t)(\eta_a)(10^{.1G_a})$, where G_a = antenna directive gain (dB); P_t = transmitter dc input power (Watts); η_t = efficiency of transmitter final (%); and η_a = antenna radiation efficiency (%).

For a trap vertical, therefore, the directive gain is approximately 0 dB, and the radiation efficiency is anywhere from 10 to 50% depending on the radial system and traps. Assuming the best, say 50%, and assuming a transmitter efficiency of 70%, the resulting erp is 63 Watts.

Now, consider the addition of a medium power amplifier—say a Heathkit SB-200 or Yaesu FL-2100A, with 1200-Watt PEP input power. The resulting erp is now 420 Watts! Sounds pretty good, huh? Well, maybe so. But first let's see what a moderate beam can do.

Consider the Hy-Gain TH-3 Junior. This is an extremely lightweight (26 pounds) beam which is small enough (12-foot boom, and approximately 25-foot elements) to be turned by a TV rotor. The TH-3 Junior boasts a gain of 8 dB over a dipole, or 10.4 dB over isotropic. And the efficiency is essentially 100%. Let's see how this stacks up against the linear. The erp of a 180-Watt transmitter with a TH-3 Junior is a whopping 1382 Watts!

This is not to mention other advantages of a beam over a vertical. First, a beam will improve the strength of the signals you hear as well as your own signal. (Remember the old addage: "You can't work 'um if you can't hear 'um.") Also, the directivity of the beam may often be used to reduce QRM from stateside stations, etc., or even line noise. Finally, TVI is reduced whenever an antenna system is raised to a higher location.

Okay, you say. But what about cost? That's the best part. First, what is the best deal on a medium-power linear amplifier that you can hope for? The Heathkit® SB-201 is about the best buy for the money at $449. A three-band rotary beam, on the other hand, can be yours for the bargain price of only $243.70, including tax, rotor, and mounting hardware. Table 1 gives a cost breakdown for the antenna and associated hardware. Notice that, with the exception of the antenna (a Hy-Gain TH-3 Junior available from most ham dealers), all other components are available at your local Radio Shack store.

By mounting the antenna on the roof, one is able to get about 15 to 25 feet of height for free, thus making the overall height about 30 to 40 feet, depending on the house. While not optimum for long-haul DX on 20 meters, this antenna will perform

quite respectably on 15 and 10 meters, and will be considerably better than a vertical even on twenty. My wife (WA4WQH) has, at last count, totaled up 101 countries on just such an antenna, driven with a KWM-1!

Although the TH-3 Junior is my personal choice, there are several other antennas which might fit the bill. Mosley, for example, has the TA-33 Junior for only $130.00. Several companies offer lightweight quad kits, and even a CB antenna turned horizontal would be a good bet. If you just can't bear to mount the antenna on the roof of your house, a telescoping mast could be substituted for a slight increase in cost. Any way you do it, such an antenna system will be the best buy in a linear on the market. 73 and good DX.■

The Chicken Delight Beam

—a tasty morsel for 10

Requires a Crossbow.

The Chicken Delight 10 meter beam is a quick, inexpensive, and effective monoband yagi. There's no need for truck or UPS shipments, just a trip to Radio Shack.

The main ingredient is a Radio Shack Archer® 3-element CB (known around these parts as chicken band) beam. This one is stock number 21-933, known as the Crossbow™ III. This lightweight beam can be easily modified for 10 meter operation. The element spacing and lengths must be changed as well as the gamma match network.

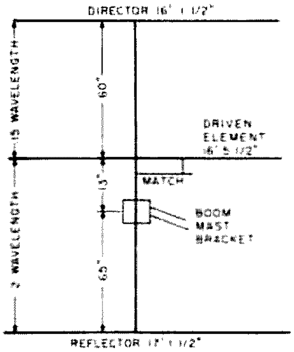

Fig. 1.

The Dimensions

The distance between the reflector and the center of the boom mast bracket remains at 65", but the boom bracket center to the driven element dimension is shortened to 13". The driven element to director distance is increased to 60". These dimensions create a yagi with a .2-wavelength reflector spacing and a .15-wavelength director spacing. The reflector element length is 17' 1½". The driven element length is 16' 5½" and the director length is 16' 1½". These dimensions place resonance in the phone portion of the band. Transposing the above dimensions directly to the assembly instructions makes for rapid construction of the antenna.

The gamma match will need to be readjusted a small amount from the 11 meter setting. This adjustment will need to be made on an individual basis. An easy way to adjust the match is to place the beam on end, with the reflector against the ground and the antenna pointing straight in the air. Matching performed in this manner is usually close enough for practical purposes. The construction of the match is good and it takes legal-limit rf easily.

I recommend using a small quantity of anti-corrosion compound where the elements slide together, a dab of RTV on each element end sheet metal screw head, and plenty of RTV on the gamma match coax connector.

Because of the beam's light weight, it is easy to erect and may be turned by a light-duty rotor.

The performance of the Chicken Delight is far superior to the 10 and 15 meter interlaced duobander I also have up, even though the duobander is 30' higher in the air.

There is no doubt the Chicken Delight is an inexpensive, effective beam. There now can be no excuse for not using a yagi on 10 meters.■

The TR-7500 Goes Inverted

—see you on the flip-flop

Put it in reverse.

Louis E. Voeman WA2JKN
25 Tamarack Hill Drive
Poughkeepsie NY 12603

The Kenwood TR-7500 is a beautiful 2 meter FM rig. It is synthesized and has a 50-position channel switch, which, together with a +15 kHz switch, gives 100 channels. It also has selectable ±600 kHz transmitter offset and simplex for each channel. The rig comes set up with 44 × 2 = 88 preprogrammed channels to cover all repeater and most simplex frequencies listed in the ARRL 2 meter band plan. For what more could you ask?

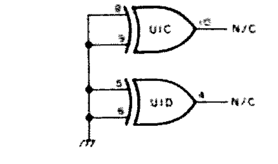

Fig. 1. The unused inputs (pins 5, 6, 8, and 9) of the IC are grounded. This is good practice for any CMOS project. U1 = 4070 CMOS "quad exclusive OR" IC. R1 = 47k Ohms, ¼-Watt resistor.

Well, you could ask for the rest of the simplex channels (147.57, 60, 63, 66, and 69). And that's no problem: The TR-7500 has a diode program board which allows you to program six frequencies of your choice. The above-listed simplex frequencies take five of the six channels. Now you have all repeater frequencies and all simplex frequencies, and one channel left on the program board. What do you do with that one channel?

How about programming it for your favorite repeater's input frequency so you can go reverse if the repeater is down and you want to QSO with your rock-bound buddy? Or perhaps you want to be able to listen on the input to determine if you are in direct range of another amateur? Good! Just program the remaining channel for the favorite repeater's input frequency. Suppose, however, there are two or more favorite repeaters? Which simplex frequencies do you give up? Another problem with programming the repeater input frequencies (at least in my case) is that the programmable channels are on the opposite side of the channel selector switch from the repeater output frequencies. In switching from output to input and back, I'd miss half the conversation.

After going through all of the above within the first couple of months of purchasing my 7500, I decided to look for a better way. The squelch knob has a pull-on push-off switch which is meant to control an optional subaudible tone encoder. I had no intention of installing that option on my rig, which meant that there was a free switch on the front panel. I decided it would be nice if I could go reverse by simply pulling out the squelch knob.

This modification will allow you to do just that. It is inexpensive (a resistor, an IC, and an IC socket) and very easy to install. No circuit board lands have to be cut. Just unsolder a couple of wires and add more. The modification has performed flawlessly for several months in my rig, and for about a month in a friend's rig.

The circuit works quite simply (see Fig. 1). The two exclusive OR gates are used as controllable inverters. The two lines inverted are labled RS and TS on the 7500's schematic. These lines control the selection of the correct offset crystal during transmit and receive. For normal operation (squelch knob pulled out), the simplex crystal is used for transmit and the receive crystal is selected by the transmit offset switch.

The circuit is constructed on the bottom of a 14-pin IC socket (see Fig. 2). All leads are brought out, the IC is plugged in, and the whole assembly is wrapped in electrical tape. (Be careful not to short anything when applying the tape.) The front panel, diode program board, and the transmit offset switch are removed. The red and yellow wires are unsoldered from the offset switch. The red wire is TS and the yellow wire is RS, coming from the phase locked loop circuit board. The red wire goes to TSIN in Figs. 1 and 2; the yellow wire goes to RSIN. TSOUT is soldered to the lug of the offset switch from which the red wire was removed. RSOUT is soldered to the lug from which the yellow wire was removed. The wire labeled "from SUB switch" is connected to the orange wire coming from the back of the squelch control. This wire comes

soldered to the small PC board on the back of the power selection switch (see the 7500 owner's manual). Plus nine volts can be taken from the brown wire, which is plugged into the driver circuit board at the point labeled C9. Don't unplug this wire, just solder to it. A convenient ground can be found next to the microphone jack. The completed circuit is fitted into the clear spot on the driver circuit board, where the subaudible tone assembly is meant to go. The rig can now be reassembled.

Operation is a joy; just dial your local repeater normally, including setting the normal transmitter offset, pull out the squelch knob, and you are operating reverse. Note that when the squelch knob is pulled out, the transmit frequency is displayed on the LED readouts; the receive frequency is set by the transmit offset switch. After using this mod a couple of times, you'll wonder why it wasn't included as original equipment in the rig. ■

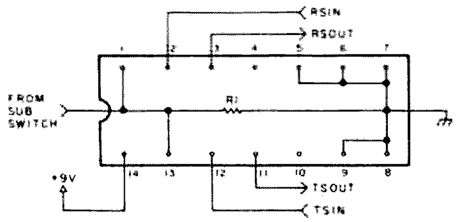

Fig. 2. Bottom view of the 14-pin IC socket.

Ready for the New Repeater Subband?

—your FT-221R can be

Simple mod does the trick.

Alex A. Webster WA6FWQ
11921 Sheldon Lake Drive
Elk Grove CA 95624

With the announcement by the FCC of the opening of 144.5 to 145.5 MHz of the 2 meter band for repeater operation, many of us were caught with rigs that would not operate in that portion of the 2 meter band. In my case, I have a Yaesu FT-221R.

Not wanting to spend a lot of money for a new rig, I decided to find another solution to the problem. After looking over the schematic diagram, I decided that a simple modification should do the trick. So, after about thirty minutes of work, I was on the new subband. I'm sure there are other ways of modifying the FT-221R to operate on the new subband, but this way seems to be the fastest and the simplest. It requires only the addition of one crystal, one jumper wire, and the relocation of two wires.

The crystal required is a 13.96666 MHz in an HC-25/U holder, shunt capacitance 34 pF, drive level 5 mW, resistance below 20 Ohms, tolerance 20 ppm, fundamental mode.

The modification steps are as follows:

1. Place the new crystal in crystal socket X09 on PB-1454 (local unit).
2. Place a jumper between terminals 3 and 6 on S2B (bandswitch).
3. Remove the wire on terminal 6 on S2C and place it on terminal 3.
4. Remove the wire from J18, pin 6 (PB-1459), that runs to S8 and place it on pin 4 of J18. Be sure to select the correct wire on pin 6 because there are two of the same color.

After the modification is completed, TC09 on PB-1454 may be adjusted to trim the crystal frequency for exactly 600 kHz offset. When this modification is incorporated in the FT-221R, it will be necessary to place the 600 kHz-Aux switch in Aux position when operating 144.5-145.5 and in the 600 kHz position when operating 146-148 MHz. ■

"Hey! That Sounds Like .01 uF!"

—intended for the blind, this audible multitester is great for everyone

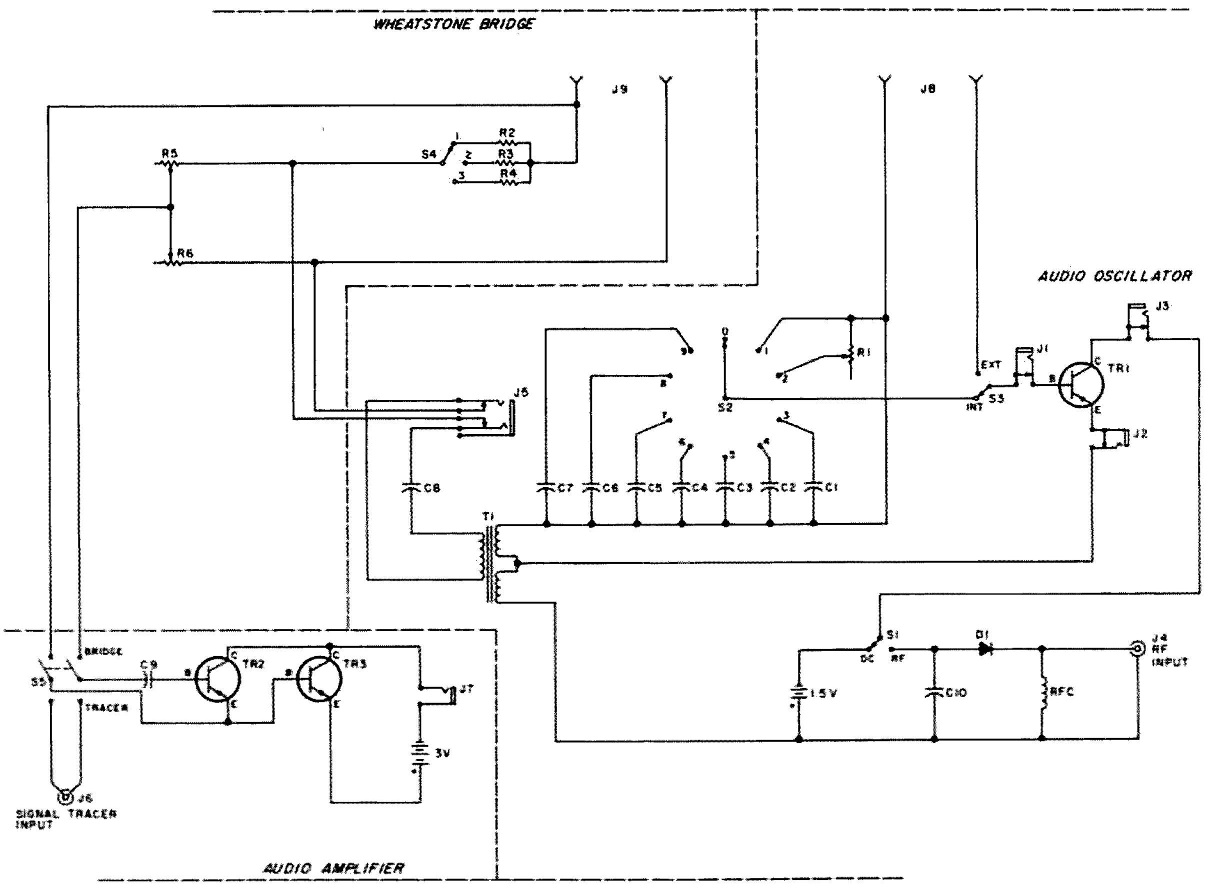

Fig. 1. Circuit diagram.

This article describes a simple but versatile test instrument designed especially for use by the sightless radio amateur or electronics experimenter. Although it may also prove useful to persons of normal vision, the instrument does not require the sense of sight for its use. All measurements of which the instrument is capable can be made using only the auditory and tactile senses. This is accomplished by 1) nulling or peaking an audio tone, 2) comparing and matching the pitch of audio tones, 3) counting the time-rate of audio pulses, or 4) reading by touch from dial plates especially suited to that purpose.

The two dials that must be read by touch are the controls for variable resistors. Dial reading is greatly facilitated by using variable resistors of the Helipot® or Spectrol® type. These are precision potentiometers requiring exactly ten turns of the control shaft to cover the full range of resistance with a high degree of linearity. When fitted with a pointer knob and a dial plate divided into ten equal divisions marked by raised dots, variable resistors of this type can easily be read by touch, in increments of one one-hundredth of the total resistance. For example, with the 10k-Ohm Spectrol, each revolution of the knob represents 1,000 Ohms and each dial division represents 100 Ohms; similarly, with the 200k-Ohm Helipot, each knob revolution represents 20,000 Ohms and each dial division, 2,000 Ohms.

Our dials were cut from thin sheet aluminum, and are about 2 inches in diameter. The raised dots marking the dial divisions were made with a center punch from the reverse side. Two dots were used at the 12-o'clock position to mark the fiducial point of zero and full resistance.

When used with appropriate test probes to be described later, this instrument has the following capabilities:

1. Checks continuity of circuits.
2. Provides an audio signal source of variable pitch for test purposes.
3. Measures capacitance from 0.0015 uF to 20 uF or higher.
4. Measures resistance from 10 to 200,000 Ohms.
5. Determines polarity of electrolytic capacitors.
6. Serves as an audio amplifier for weak signals.
7. Serves as a signal tracer for either audio or modulated rf/i-f signals.
8. Serves as an rf detector, transmitter tuning indicator, approximate frequency meter, or CW keying monitor for rf signals.

Circuitry and Applications

Fig. 1 shows the circuit diagram of the test instrument. As indicated in this figure by the dashed lines, the circuit is comprised of three basic elements: an audio oscillator, a Wheatstone bridge, and an audio amplifier.

The heart of the instrument is the audio oscillator, which can be powered by either an internal battery or an external source of rf energy. The oscillator uses a 2N107 PNP transistor in the familiar Hartley circuit. Inductive feedback is provided by T_1, which is a vertical blocking oscillator transformer from a TV set. In our case, this transformer is a Merit A-3001, with one primary and two secondary windings. The ratio of primary to secondary #1 is 1:48, and the ratio of the primary to secondary #2 is 1:1. These ratios are not critical, and any transformer of approximately similar characteristics should

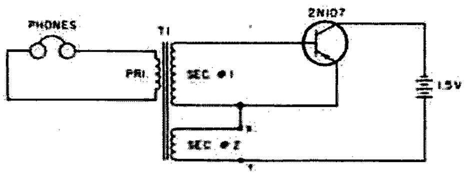

Fig. 2. Basic oscillator circuit.

serve. It is important, however, that the two secondary windings be connected so as to provide positive feedback for oscillation. The simplest way to determine the proper connections to the transformer is to temporarily hook up the basic oscillator circuit with clip leads as shown in Fig. 2. If oscillation is not obtained, as indicated by a low-pitched buzz in the phones, reverse the connections of secondary #2 at points X and Y.

A characteristic of this oscillator is that the frequency of oscillation can be varied over a wide range by inserting different values of resistance, capacitance, or inductance in series with the base lead of the transistor. Low values of series resistance produce low-pitched tones, and high values, high-pitched tones; whereas low values of series capacitance produce high-pitched tones, and high values produce low-pitched tones. The frequency of oscillation is highly sensitive to small variations of this kind, so that even quite small variations in series resistance or capacitance can be detected by a keen sense of pitch, which most sightless persons possess.

The important point, however, is that two resistors of equal resistance, or two capacitors of equal capacitance, when alternately inserted in the base lead, will produce tones of the same pitch. This characteristic provides a means for determining the value of an unknown resistance or capacitance by comparing the pitch of the tone it produces with the pitch produced by a standard resistor or capacitor of known value contained in the test instrument.

The standard resistor incorporated in the instrument for measuring resistance by the tone-comparison method is the 200,000-Ohm Helipot, R_1. It is inserted in series with the transistor base circuit when the selector switch, S_2, is placed in position 2.

Referring to Fig. 1, the procedure for measuring an unknown resistance by the tone-comparison method is as follows:

1. Connect the unknown resistance across the test leads plugged into the jacks at J_8.
2. Plug the headphones into J_5 (or J_3).
3. Set the SELECTOR switch, S_2, at position 2.
4. Apply battery power to the oscillator by throwing the power supply transfer switch, S_1, to the DC position.
5. Throw the tone comparison switch, S_3, to the up or EXTERNAL position and note the pitch of the tone heard. This is the tone produced by the unknown resistance.
6. Now throw S_3 to the down or INTERNAL position, thereby substituting the standard resistor, R_1, for the unknown resistance. Adjust R_1 until no difference in pitch is heard when S_3 is thrown from one position to the other.
7. R_1 now has the same resistance as the resistor under test. Read this value

from the dial of R_1. This is readily done by noting the number of dial divisions and knob rotations passed over as the control knob is turned back to the zero-resistance position. As previously noted, each dial division represents 2,000 Ohms and each knob rotation, 20,000 Ohms.

On our instrument, this method of resistance measurement was found to be more useful for resistances greater than about 1,000 Ohms. For smaller values of resistance, the pitch becomes so low that all tonal character is lost and an accurate matching of pulse rates is more difficult. However, resistances under 1,000 Ohms can be accurately measured by the Wheatstone bridge.

Seven capacitors, C_1 through C_7, are incorporated in the instrument as standards for estimating capacitance. They are inserted individually into the base circuit by setting the SELECTOR switch, S_2, in positions 3 through 9. These capacitors range in value from 0.0015 uF to 0.1 uF in increments such that the capacitance is doubled each time the selector switch is advanced one position. In our case, we were fortunate enough to find in the junk box a multi-section capacitor containing all of these seven capacitances in one shielded can. Individual capacitors will serve just as well, of course, though perhaps not as neatly.

The procedure for estimating capacitance is the same as that for measuring resistance, except that a tone match or a near tone match is obtained by rotating the SELECTOR switch from position 3 to position 9. As the standard capacitances are available only in discrete steps, it is unlikely that a perfect tone match with the unknown capacitance can be obtained. More commonly, the pitch produced by the unknown capacitance will be bracketed by two SELECTOR switch positions, one giving a higher pitch and the other a lower pitch than the capacitor under test. The unknown capacitance is then approximated as somewhere within the range of capacitance represented by these switch positions, giving consideration to the relative differences in pitch of the three tones.

Although the highest standard capacitance provided is 0.1 uF, much higher values can be measured by using a different technique. As the unknown capacitance across the test leads is increased, the audio tone becomes lower in pitch; for capacitances greater than 0.5 uF, the pitch becomes so low that individual pulses can be counted. On our instrument, pulse rates were counted for high-quality oil-filled capacitors of different values as shown in Table 1.

These pulse rates were counted by ear with the phones plugged into J_5. A stopwatch was used for timing purposes, but the one-minute intervals from WWV could also be used and probably would be more convenient for the blind. These same pulse rates would probably not be duplicated in replicas of the tester, but they are indicative of what is to be expected. Each instrument would need to be calibrated individually, which is a simple process if a variety of marked capacitors is at hand.

Capacitance (uF)	Pulses Per Minute
0.5	360
1	180
2	90
3	54
4	45
8	24
10	20
20	10

Table 1.

The capability of operating from an external rf source as well as from the internal battery greatly increases the utility of the audio oscillator. With the power transfer switch, S_1, in the RF position, the oscillator may be powered by rf injected at J_4. The components RFC, D_1, and C_{10}, comprise a half-wave rectifier and filter for converting the rf current to dc. More will be said about this feature of the instrument in connection with the rf pickup to be described later.

Note that the power transfer switch, S_1, also serves as the off/on switch for the battery and should be left in the rf position when the instrument is not in use.

One final comment on the oscillator may be worthwhile. The closed-circuit jacks, $J_{1\text{-}3}$, were installed in case it might be desired to insert other test components into the oscillator circuit. The audio tone can be heard with the phones plugged into either the base jack, J_1, or the collector jack, J_3, as well as the regular phone jack, J_5. A useful application of the emitter jack, J_2, was discovered quite by accident. An electrolytic capacitor inserted into the circuit at J_2 will have a dc voltage impressed across it. If the polarity of the capacitor is correctly observed, the capacitor will slowly charge, and the pitch of the tone heard with the phones plugged in at J_5 will gradually rise until it pinches off when the capacitor reaches full charge. If the polarity of the capacitor is incorrect, the tone may continue indefinitely or it may pinch out as before, but at a much slower rate. This characteristic can be used to determine the polarity of electrolytic capacitors or to detect leaky electrolytics.

Wheatstone Bridge

The Wheatstone bridge is energized by a tone from the audio oscillator. The audio tone is automatically transferred to the bridge input by the switching function of J_5 when the headphone plug is removed from that jack. The bridge circuit is composed of four resistors: any one of the three standard resistors, R_2, R_3, or R_4 selected by S_4; the variable balancing resistor, R_5; the Spectrol variable resistor, R_6, and the unknown resistance, R_x, connected across the test leads at J_9. The theory of the Wheatstone bridge is explained in any high school physics book. Suffice it to say here that the bridge is in balance when the ratio of a standard resistor (R_2, R_3, or R_4) to the balancing resistor, R_5, is equal to the ratio of the resistor under test, R_x, to the Spectrol nulling resistor, R_6. The instrument provides three bridge ratios: 1:10, 1:1, and 10:1. The upper limit of resistance that can be measured by the bridge is the maximum resistance of R_6, 10,000 Ohms, multiplied by the bridge ratio. Thus, if the bridge ratio is set up as 1:10, the bridge will measure up to 1,000 Ohms in calibrated dial divisions of 10 Ohms each. If the bridge ratio is set up as 1:1, resistance values up to 10,000 Ohms can be measured with dial divisions of 100 Ohms each. If the bridge ratio is set up as 10:1, resistance values up to 100,000 Ohms can be measured with dial divisions of 1,000 Ohms each.

It may be noted that the standard resistors, R_{2-4}, need not be precision resistors. In fact, they need not even have the nominal values indicated. The only criterion for selecting these resistors is that they must have some value that will allow the desired bridge ratio to be obtained by adjusting R_5. The values indicated were chosen merely because they make the proper setting of R_5 fall at about midscale.

Three precision resistors will be required, however, for initially setting up the bridge to measure unknown resistances. Ideally, these precision resistors would be 500, 5,000, and 50,000 Ohms, but, again, this is not necessary. The closest we could come from our junk box was 500, 1,000, and 79,000 Ohms, and these values will be used in the explanation to follow.

To set up the bridge for a 1:10 ratio, proceed as follows:

1. Connect the 500-Ohm precision resistor across the test leads plugged in at J_9.
2. Connect the output of the bridge to the input of the audio amplifier by throwing the transfer switch, S_5, to the BRIDGE position.
3. Throw S_3 to INTERNAL (down) position.
4. Plug the headphones into J_7. This automatically turns on the audio amplifier.
5. Set the bridge RATIO switch, S_4, to position 1.
6. Set the nulling Spectrol, R_6, to 5,000 Ohms by turning its pointer knob 5 revolutions counterclockwise from the zero resistance setting. If your precision resistor in step 1 is some value other than 500 Ohms (any value in the range 100-900 Ohms would be satisfactory), set R_6 to read ten times the value of your precision resistor.
7. Set the SELECTOR switch, S_2, to position 8. Other positions of this switch can be used if a higher- or lower-pitched tone is preferred. On our instrument, position 8 yields a pleasing tone of about 500 Hz.
8. Turn on the audio oscillator by throwing the power transfer switch, S_1, to the DC position. A tone will now be heard.
9. Null this tone by adjusting the balancing resistor, R_5, until the tone disappears or is weakest. Once the null position is found, *do not move this control again.*
10. The bridge is now in balance for a 1:10 ratio. Remove the test leads from the precision resistor and clip on the unknown resistance. Find a new null by adjusting the Spectrol potentiometer, R_6. The unknown resistance will be one-tenth of the resistance read from the Spectrol dial at the new null setting.

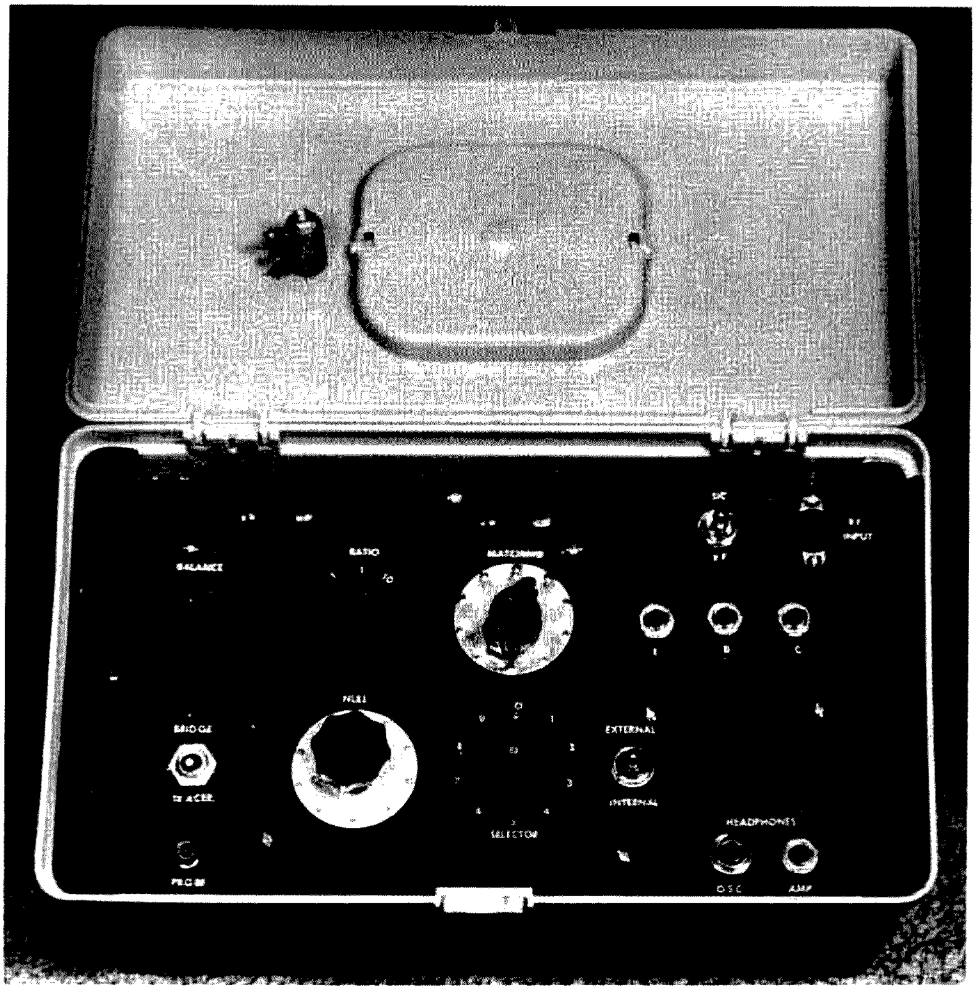

Photo A. Related controls are shown here, grouped to facilitate memorizing the panel layout. A precision resistor used for setting up the bridge is bolted to the lid for safekeeping.

To set up the bridge for a 1:1 ratio, the same procedure is followed except that the 1,000-Ohm precision resistor is clipped to the test leads, and R_6 is initially set to read 1,000 Ohms. If your precision resistor is of some other value in the range 1,000 to 9,000 Ohms, set R_6 to that same value. The bridge RATIO switch, S_4, is set to position 2. With the 1:1 ratio, the null-point reading of R_6 for an unknown resistance will directly indicate that resistance.

To set up the bridge for a 10:1 ratio, again proceed as before, but clip the 79k-Ohm precision resistor across the test leads and set R_6 to 7,900 Ohms. If your precision resistor is of some other value in the range 10k-90k Ohms, set R_6 to read one-tenth the value of your precision resistor. The bridge RATIO switch, S_4, is set to position 3. With the 10:1 ratio, the null point reading on R_6 for an unknown resistance must be multiplied by 10 to equal the unknown resistance.

Audio Amplifier

The circuit of the audio amplifier is about as barebones as it can be made, consisting only of the two

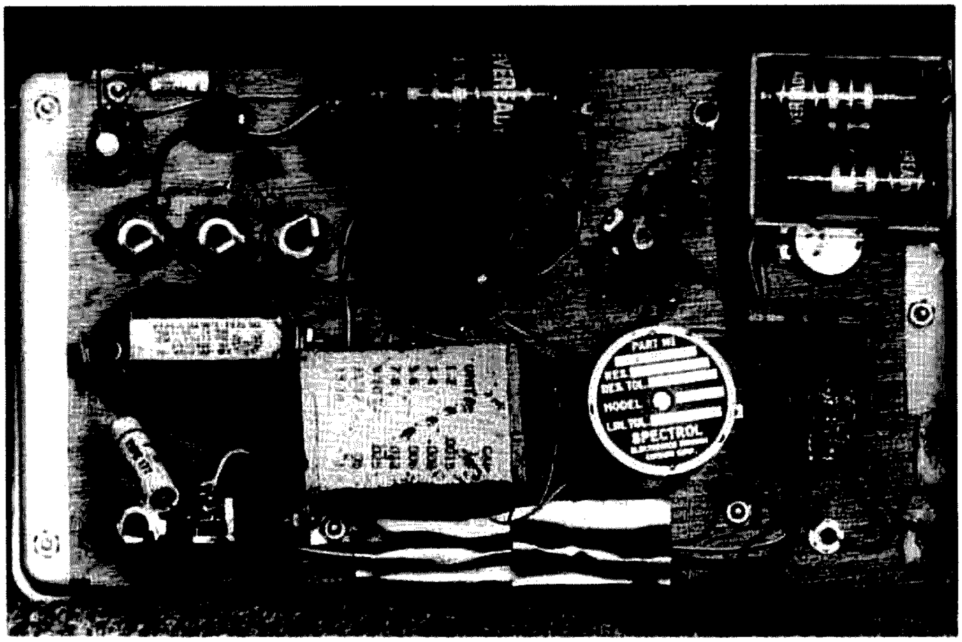

Photo B. All components are mounted on the panel, as shown here.

directly-coupled transistors, $TR_{2,3}$, and the coupling capacitor, C_9. The DPDT switch, S_5, serves to transfer the amplifier input either to the bridge output or to the jack, J_6, for the signal-tracing probes. The amplifier is powered by a separate 3-volt battery supply. There is no on/off switch, as this function is served by plugging or unplugging the phones at the open-circuit jack, J_7. Initially, we tried to operate the audio amplifier and the oscillator from a common 1.5-volt battery, but this did not work out because of audio leakage around the Wheatstone bridge that made it impossible to obtain a distinct null. The separate power supply for the amplifier cured this trouble, and raising the supply voltage to 3 volts gave the amplifier a little more clout.

Construction and Arrangement of Parts

Construction of the test instrument is easy and simple. No PC boards are needed, and the only material to be drilled is the 1/8-inch plywood panel. Our tester was built in a plastic cosmetic box purchased at the local drugstore for about $3. The box is approximately 12 inches long, 7 inches wide, 6 inches deep, and has a hinged lid with a latch and a recessed carrying handle. Originally, the box had a removable tray which, unfortunately, was divided into compartments with rounded bottoms so that it could not be used as a mounting panel. The supporting ends of the tray were sawed off, therefore, and attached to the ends of a plywood panel. All components are mounted on this panel, which can be lifted out for battery replacement or servicing.

Electrically, the placement of parts is not at all critical, but a little thought should be given to grouping associated controls in some coherent fashion that will be easier for a sightless user to memorize. The external appearance and panel arrangement of our version of the instrument are shown in Photo A. Photo B shows the "works" underneath the panel. Referring to Photo A, the controls related to the oscillator occupy the right half of the panel; those for the bridge and audio amplifier, the left half. At top center are the test-lead jacks, J_8. In line below these jacks, are the pointer knob with embossed dial plate for the Helipot, R_1, and the pointer knob for the SELECTOR switch, S_2. In the right corner are the power supply transfer switch, S_1, and the jack, J_4, for the rf pickup. The two phone jacks, J_5 and J_7, are in the lower right corner. The tone comparison switch, S_3, is to the right of the selector switch, and the three jacks, J_{1-3}, are in line to the right of the Helipot dial.

In the lower left corner is the jack, J_6, for the signal-tracing probes; above this is the transfer switch, S_5, for the audio amplifier input. To the right of this switch is the other embossed dial for the Spectrol bridge-nulling resistor, R_6. Above this dial is the bridge RATIO selector switch, S_4, and to the left of this switch is the control for the bridge-balancing resistor, R_5. Finally, at top left are the jacks at J_9 for the bridge test leads.

The reader may wonder why all of the controls are so elegantly labeled on an instrument intended for use by the blind. The truth of the matter is that the builder wanted to try out those rub-on letters, and could not resist the urge to add this utterly useless embellishment.

Accessories

Accessories for the test instrument include, in addition to the three precision resistors for setting up the Wheatstone bridge, a pair of test leads, an audio signal-tracing probe, an rf signal-tracing probe, and an rf pickup (Photo C).

The test leads are unshielded, with a clip at one end and a plug at the other, to match the panel jacks at both J_8 and J_9.

The audio signal-tracing probe uses shielded wire with a phone plug at one end to match jack J_6 and an ordinary test prod at the other. A short grounding lead with a clip is provided to complete the ground circuit at the prod end.

The circuit for the rf signal-tracing probe is shown in Fig. 3. The components are mounted on a narrow strip of perfboard and inserted into a cylindrical aluminum shield can about 1 inch in diameter and 5 inches long. The shield can we used was obtained at the drugstore as a small butane cylinder intended for refilling cigarette lighters. After releasing *all* of the butane outside in the open air (butane and air form an explosive mixture—*don't* do this in the shack), the valve end of the cylinder was sawed off and replaced with a wooden disk to hold and insulate the probe tip. The wire lead for the probe is shielded phono cable with a phono plug to match J_6. A short grounding lead with a clip is provided to complete the ground circuit at the probe end.

With a short antenna

connected to the probe tip, and the probe feeding the audio amplifier, local broadcast stations can be heard with good volume (although with considerable QRM if there are several stations). With a good antenna and a tuned circuit ahead of the probe, we might also claim that the test instrument will serve as an emergency BC receiver.

With the power transfer switch, S_1, in the RF position, and a short random-length wire plugged into J_4 for an antenna, the oscillator can be powered by any strong rf field in the high-frequency range. Sensitivity is much increased, however, by using a tuned pickup. This pickup consists of a simple parallel-tuned circuit, enclosed for convenience in handling in a cylindrical cardboard container about 2 inches in diameter and 6 inches long (see Photo C and Fig. 4). The container we used was originally full of ready-mixed biscuit dough. We cut off one of the metal ends, disposed of the dough, and removed the tinfoil inner lining, since no shielding is desired for the pickup. The components of the tuned circuit are then wired and inserted, using the metal end left in place as a mounting plate for the variable capacitor. A wooden disk restores the strength of the open end.

The frequency range covered by the pickup is left to individual preferences. We selected a small variable capacitor of perhaps 150-pF maximum and a coil from a defunct surplus item that looked as though it might tune the 80- and 40-meter amateur bands. Actually, the combination tunes the range 3.2 to 11.4 MHz, which suited our particular needs quite well. The range covered by the pickup could be extended if desired by arranging to tap the coil, or by using plug-in coils of different sizes.

With this pickup plugged into J_4, the oscillator will work with the pickup about 3 inches away from the coil of our grid-dip meter, which would seem to indicate fairly good sensitivity. It also works well as a transmitter peaking indicator or CW keying monitor, with the pickup on the operating table about 6 feet from the transmitting antenna tuner.

The resonance point of the tuned pickup is fairly sharp, so that the pickup also could be made to serve as a wavemeter by fitting the variable capacitor with a calibrated dial readable by touch. Although our efforts did not extend that far, this possibility is pointed out to those who might wish to increase the versatility of the instrument in that direction.

Credit for the concept and general design of the test instrument is due W4RYY, who had previously used the basic circuits individually but had never combined them as an integrated unit. Except for a few minor refinements, all I did was to build the instrument and prepare this description of it. ■

The W4HCY Antenna System

—give this new design a try

The W4HCY antenna system is designed to provide maximum possible current throughout *all* of a radiating antenna during any or all parts of an alternating cycle of antenna current for whatever frequency the antenna is tuned and operating.

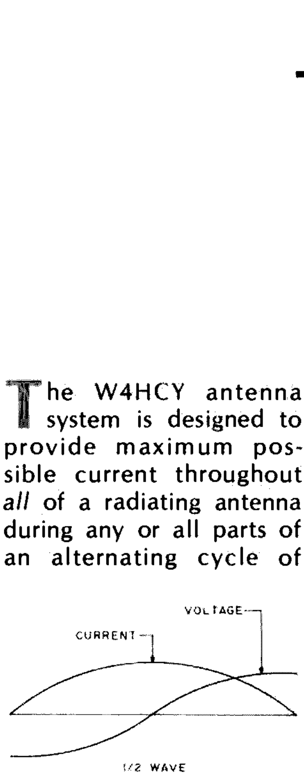

Fig. 1. From The ARRL Antenna Book *(page 25).*

By far, the greatest factor contributing to radiation from any antenna is its magnetic field, which is produced directly by the current flow through the antenna. In my opinion, failure to provide for maximum full-length antenna current in amateur antennas up to this time has been due to a failure either to recognize this fact, or to design provision for it.

Therefore, the requirement necessary to provide maximum full-length antenna current is to develop a design that will force maximum current flow throughout the full antenna length. The W4HCY design is engineered to do this job.

Throughout all of the articles on antennas that I have been able to find, none of them offers an effective solution to this problem. In fact, some give explanations on the operation of antennas that, to me, are misleading.

I am not saying that the writer is wrong in his own understanding, but the choice of words and explanation used do not, in my judgment, fit properly into the fundamental factors which determine operation of ac circuits.

Here is an example: *"When a charge reaches the end of the antenna and is reflected, the*

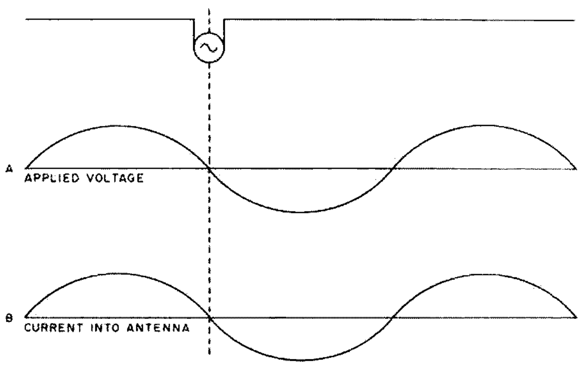

Fig. 2. From The ARRL Antenna Book *(page 28).*

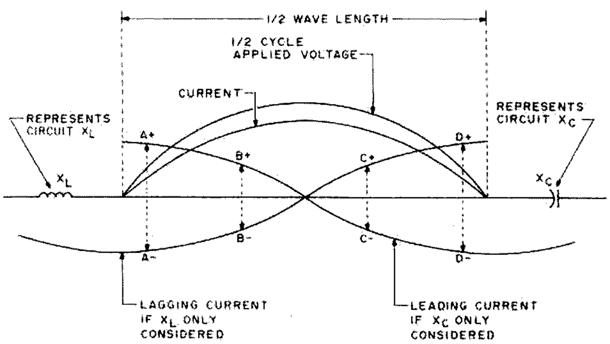

Fig. 3.

direction of current flow reverses, since the charge is now traveling in the opposite direction."[1]

The word "reflected" is misleading in that it implies that there is some kind of barrier at the end of the antenna that a charge strikes and bounces back from. This is similar to an earlier example in the same article wherein it is said that a ball traveling along a trough bounces back whenever it strikes the far end.

"Bouncing back" and "being reflected from" are poor descriptions of what really happens. The following is a more accurate description of what actually happens:

At the end of each half cycle, the voltage from end to end of a resonant antenna reverses polarity and the current is *driven* back in the opposite direction, not reflected.

The same article further states that the current and voltage are out of phase by 90°, and Fig. 1 shows the phase difference between voltage and current along a half-wave antenna. I fail to understand such an explanation for current and voltage relationship in a resonant antenna.

If current flowing in an antenna circuit were this far out of phase with the voltage, I doubt that it would be possible to keep the overload relay closed.

Further on in the same antenna article, the following *correct* statement is made in describing operation of antennas: *"Exactly at resonance, the current at the input terminals will be in phase with the applied voltage."*[2]

Yes! And who wants an antenna that is not tuned to resonance at the operating frequency? Fig. 2 illustrates the above quote wherein voltage and current are in phase. Yes, Fig. 2 shows the way it really is.

Now let's take a good look at what actually happens in an antenna circuit when we make use of accepted fundamentals which govern the operation of alternating-current circuits. These would be resistance (R), inductive reactance (X_L), capacitive reactance (X_C), alternating voltage (alternating polarity), and alternating current.

It will not be necessary to describe here in detail all these functions, but it is essential to state that current in a capacitor leads the voltage by 90°, and that current in an inductance lags the voltage by 90°. It is necessary for proper balance in a series resonant circuit that the X_L and X_C be adjusted to balance against each other sufficiently to bring the current in phase with the applied alternating voltage.

Fig 3 shows how it works in a half-wave antenna. At radio frequencies, a straight wire or conductor presents inductance (X_L) to rf current. The spacing between antenna conductors and between antenna conductors and ground presents capacitance (X_C) to rf current. When these reactances are combined (made equal) to resonate an antenna to a given frequency, the antenna current flows *in phase* with the antenna voltage. Reactances X_L and X_C cancel, and only resistance remains; voltage and current are in phase. Note that the A+ and A− currents cancel each other, leaving only pure resistance in the half-wave length of antenna wire. Other examples are shown at B+ and B−, C+ and C−, and D+ and D− for all the length of the antenna. The inductor and capacitor shown at the ends of the antenna represent the total X_L and X_C of the whole circuit. They are not intended in this case to represent a physical presence as shown in the drawing.

Now let's take a look at a typical antenna installation along with the circuitry inside a transmitter which is the source that supplies energy to the antenna. To illustrate the theory of operation, I have chosen to use the typical pi-network-type final transmitter circuit. However, the basic fundamentals of transferring radio energy to antennas are the same for other types of antenna coupling. Fig. 4 is a typical example. The transmission line is omitted for simplicity.

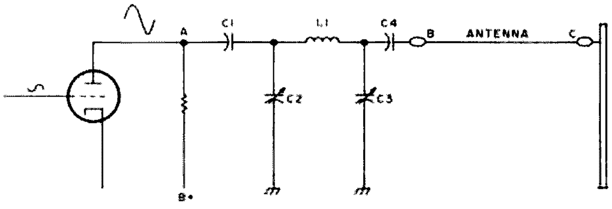

Fig. 4.

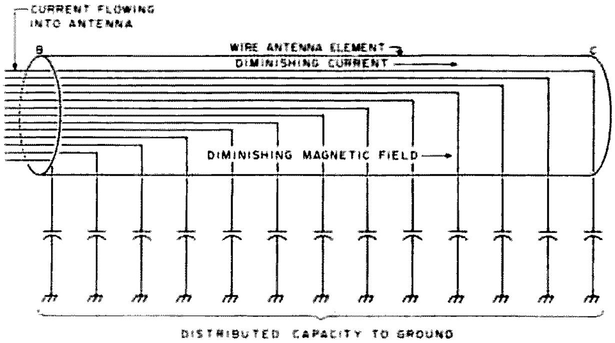

Fig. 5.

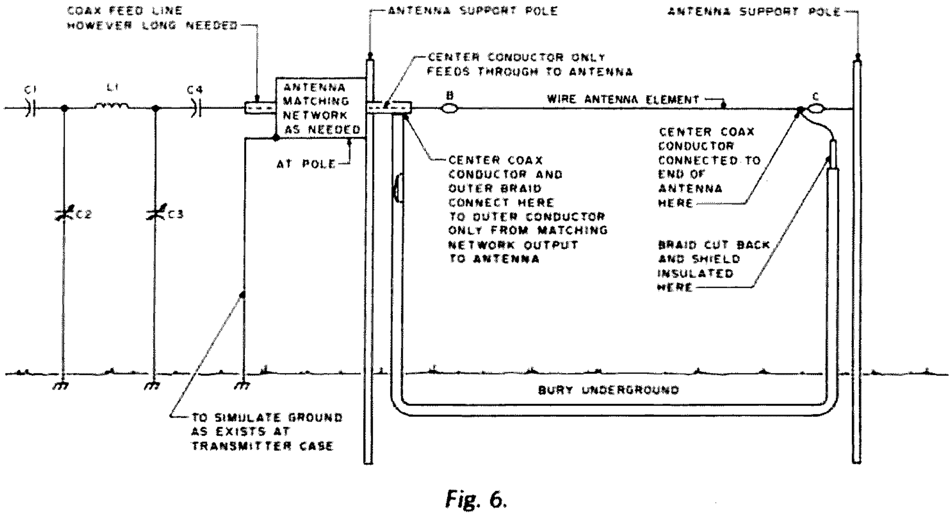

Fig. 6.

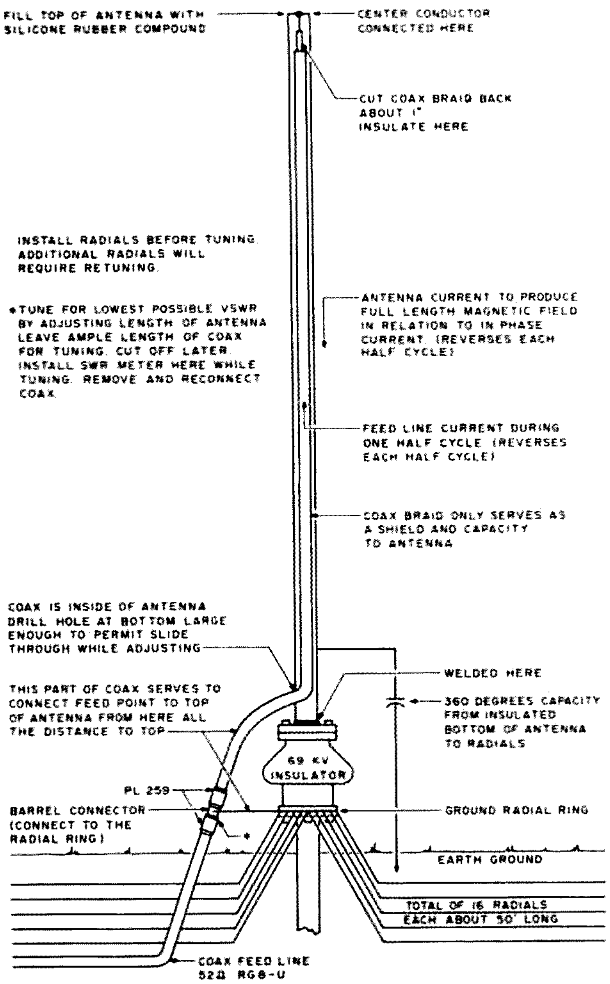

Fig. 7. The W4HCY 40-meter antenna now in operation is made of 1/8"-wall aluminum tubing in four sections: 2 inches o.d. at the bottom and telescoping to 1 inch o.d. at the top. It is free-standing and approximately 33 feet long.

How does it work? The desired frequency appears at tube grid where it is amplified, inverted and appears at coupling capacitor C1 at point A. In a correctly operating transmitter, the frequency at this point never changes. All the other parts of the circuit *must* be adjusted to provide an in-phase voltage with the tube plate voltage at point A.

Capacitor C1 couples this ac voltage to the tank circuit pi network (C2, L1, and C3). When tuned to resonate with the transmitter frequency at point A, the action of inductor L1 and capacitors C1 and C2 set up an oscillating current in these three components that is free-running at the transmitter frequency. It will, however decay because of circuit losses unless it is reinforced by the tube output. This action begins at the beginning of each free-running half cycle and continues throughout each half cycle.

Ok, we all agree up to this point. This is old stuff. I have included these operating functions only to complete the picture.

So now let's examine the antenna operation. I have chosen a longwire parallel to the ground. Does it radiate because of something mythical, or some type of tangible reflecting substance at the end of the antenna at point C? Absolutely not.

No current can ever flow anywhere except where there is a voltage (potential) difference between two points wherein it is desired that a current should flow. But, the antenna shown in our example, Fig. 4, will work. How?

Whenever the loading capacitor, C3, is adjusted to load the antenna, the resonant tank circuit does not go out of resonance as one might expect. Why? Because the capacity in C3 is transferred in part to the distributed capacity that exists between the antenna wire and ground. Resonance is maintained, however, because more intensive use of the antenna capacity to ground is now made and current is now flowing in the antenna.

Right here is where the real important thing about this article begins. Let's watch it carefully.

As the voltage increases on the end of the antenna wire nearest the coupling capacitor at point B, the current flowing first sees the portion of the distributed capacity that is nearest to this end of the antenna from point B to ground. Therefore, this capacity becomes charged most and there is a *diminishing* charging current available for the remainder of the distributed capacity out to the far end of the antenna at point C. Fig. 5 shows this current flow action.

The W4HCY antenna system (Fig. 6) provides a feed point and current return circuit which forces a strong, full-length antenna current through all of the antenna, thereby providing a stronger, longer magnetic field for maximum possible magnetic radiation.

Ground connection from the matching network is made to the far end of the antenna through the shielded coax. The shield must be left ungrounded at the outer end of antenna point C. Outer braid is only used to serve as a shield. It is not a part of the antenna. It does not carry antenna current. Only the antenna radiates.

I have a home-brew 1/4-wave vertical antenna for 40 meters that is made of heavy-wall aluminum tubing and is free-standing, supported by a 69-kV insulator. There are 16 underground radials, each about 50 feet long.

I have changed the feed line on this antenna as shown in Fig. 7. No other changes were necessary except lengthening the antenna by 8-1/2 inches to offset the increased X_C due to its higher efficiency to the same capacity radials and added X_C of the coax shield braid inside the vertical radiator.

The use of coax, by which the braid serves as a shield between the center conductor and radiating element, introduces extra X_C into the antenna tuning network. This added X_C must be considered in the design. Compensation can be made by making the antenna element longer, using a larger diameter antenna, spacing the coax to the exact center of the antenna, and using smaller diameter coax such as RG-58/U.

Although this antenna is only a 1/4-wave radiator, the results have been very rewarding. I have never operated it yet when I did not get back reports such as, "strongest signal on the band," etc. My monitor scope shows a 25 to 30 percent increase in talk power.

Another operating feature is that the antenna appears to operate at a much higher Q. This is evidenced by much sharper receive and transmit action. I find that I must tune very sharply to a received signal

to prevent distortion. At only 100 cycles each side of a received signal, distortion becomes annoying. Before changing to the antenna feed as described herein, the same off-frequency tuning would only change the voice quality of the received signal.

I have checked the transmitting improvements by asking other amateurs to tune slightly off my frequency, and the reports have been the same (very narrow and very strong) and without even asking about audio quality, I almost always hear reports of excellent audio.

The W4HCY antenna feed system is applicable to a large variety of antennas, except those that already use full-current feed, such as a terminated rhombic, quad, delta loop, etc.

I am presently in the process of applying it to my five-element monoband yagi for 20 meters. This will require a matching network which I do not have. However, I have put it on the air a couple of times using a James Millen Co. antenna tuner. The same improved operation is evident both on receive and transmit. The feed method for the driven element on this beam is shown in Fig. 8. The coax inside the antenna serves only as a shield to prevent cancellation of the antenna element current. Be sure to connect as shown. Always insulate the outside end of the braids.

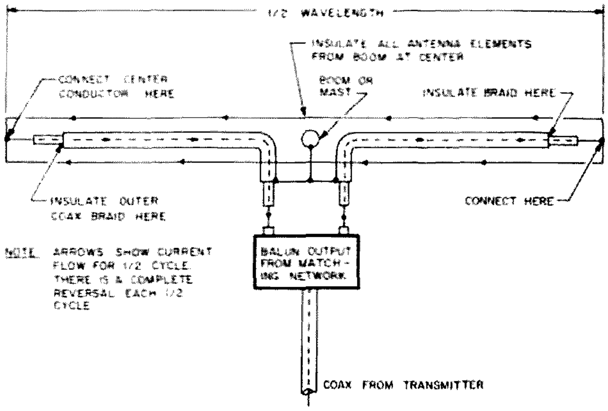

Fig. 8.

This system can be used on multiband antennas by using a separate shielded feedline inside the driven element and correctly connecting to each band outer end section of the antenna. Only one feedline up to the antenna will be necessary.

I am very confident that this antenna system will outperform most other conventional antennas. Radiation will be greatly improved and signals transmitted from the antenna will require less space on the band.

Please feel free to use the system for your own pleasure. I will be delighted to hear from you about your results—pro or con. But, I will not be able to answer a multitude of letters.

I reserve the right to require permission from me or my heirs for the use of this system by anyone who may desire to use or apply it in any way to antennas manufactured and sold for profit.■

A 3-Band Mast-Mountable Miniquad

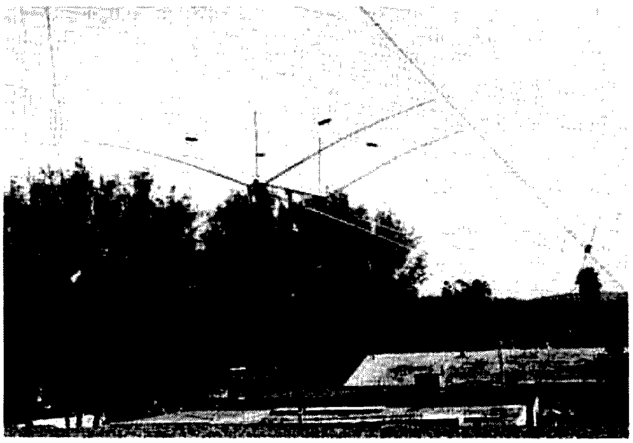
—a quad need not be monstrous

Small in size, high in performance.

Combining two compact quad designs into one results in a miniquad with lots of appeal. It's small in size and cost and high in performance. So, after numerous requests during QSOs for a detailed description of this somewhat unorthodox quad, I decided to write it up for *73 Magazine*.

What Is Different About It

A full-size 20-meter quad measures approximately 19′ x 19′. This miniquad for 10, 15, and 20 meters measures 6½′ x 14′. The unorthodox part of this design is that the 20-meter loops (using loading coils) are mounted between the 10- and 15-meter loops. It wasn't planned that way, but the physical dimensions required to resonate each band resulted in that configuration. Also, all three bands use vertical wire stubs both for tuning and to reduce the vertical dimensions.



This is the miniquad after two years of operation (lowered for refinishing spreaders). Optional materials for spreaders are fiberglass (expensive, but non-deteriorating) or PVC tubing, if properly braced. (See Reference 3.)

Why You'll Like It

You will find that, unlike the full-size quad, this one is a breeze for one man to handle and mount on a tower. What's more, because of its small wind load, it can be mounted on an ordinary TV rotor and a low-cost telescoping TV mast. Also, this antenna requires only about half the copper wire of a full-size quad. Overall, that represents quite a savings for the typical low-budget ham like me!

While the miniquad may have slightly less gain than a full-size quad, for most of us, the advantages far outweigh the slight loss. The miniquad performance is really impressive when compared with the inverted vee antenna, especially when the band appears to be dead on the inverted vee. I have made some excellent DX contacts since switching to the miniquad.

How It Evolved

Being dissatisfied with the performance of an inverted vee on 10, 15, and 20 meters, I made a search of ham magazines and antenna books for various types of beams and quads. I decided that the quad, which requires less height than a yagi-type beam, was best for this QTH, as the degree of acceptance by the XYL of another antenna on top of the house was calculated to be inversely proportional to the square of antenna height!

Two interesting quad designs were found. Neither was small enough to fit on

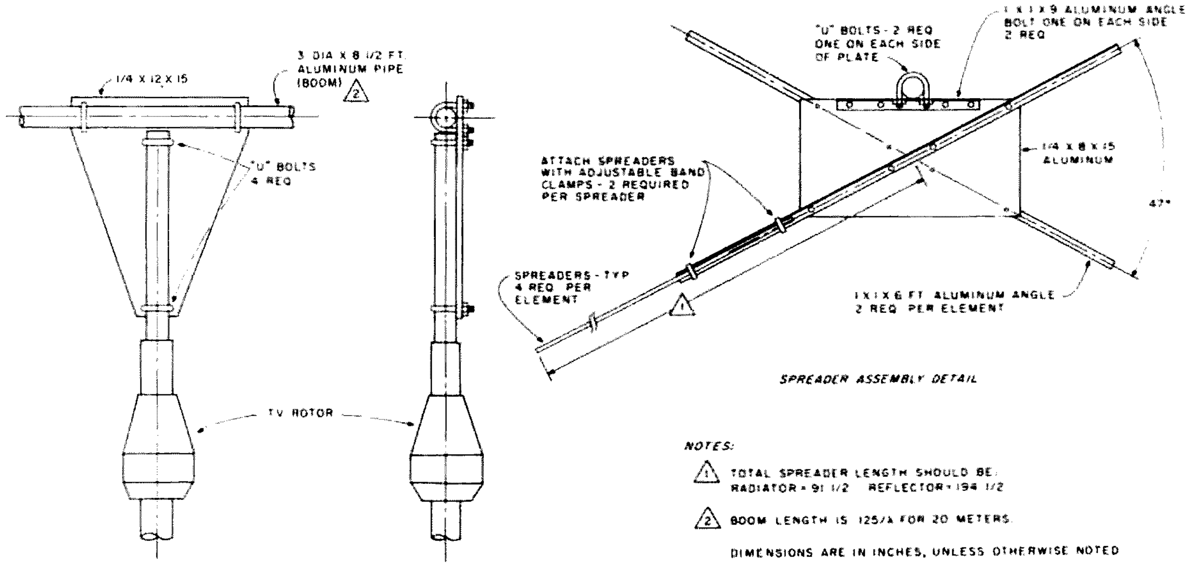


Fig. 1. Boom-to-mast assembly detail.

the bamboo spreaders donated by a friend, however, so I decided to combine two designs and make a more compact antenna. One was the Low Profile Quad[1] and the other, the Japanese Quad.[2]

The Low Profile Quad consisted of folding the vertical sides of a full-size quad to form long, narrow, vertical loops set in a few inches from the vertical sides of the quad. This reduced the dimensions of the 20-meter full-size quad from 19′ x 19′ to 12′ x 19′. The resonant frequency of the Low Profile Quad was adjusted by sliding shorting bars up or down on the narrow loops.

The Japanese Quad used loading coils, four per element, which reduced the full-size 20-meter quad to 12′ x 12′. By combining the Japanese Quad with the Low Profile Quad, a further reduction was obtained down to 6′ x 12′ for 20 meters.

First, I experimentally constructed a two-element (radiator and reflector), 20-meter-band-only miniquad. It used loading coils and folded loops with shorting bars. In an effort to simplify the design, the folded loops and shorting bars were replaced with vertical wire stubs spaced a few inches in from the sides of the antenna. The wire was attached at the bottom side of the quad loop and supported vertically with monofilament fish line to the top. Tuning was done by pruning the vertical wire. The longer the wire, the lower the resonant frequency.

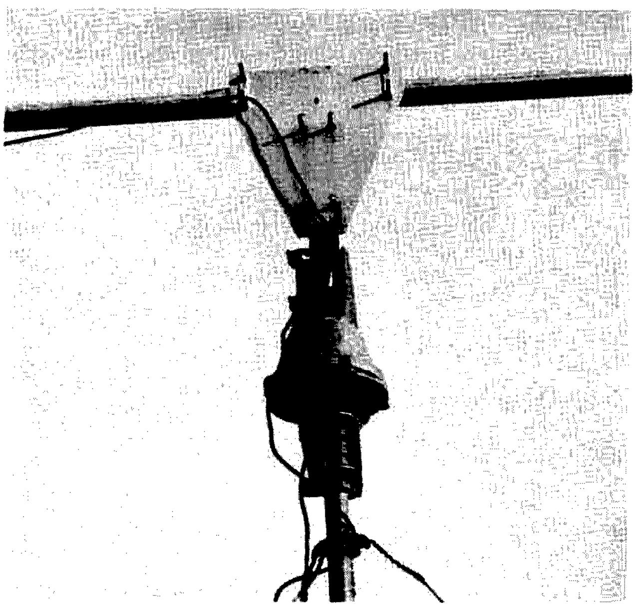
The 20-meter miniquad was placed on a TV rotor, and the mast was raised to about 35 feet. After some additional pruning, the antenna was tested in actual use with excellent results.

After testing the 20-meter design, the antenna was taken down and the 10- and 15-meter elements were added. The 10-meter loops were installed inside the 20-meter loops. Resonating the 15-meter loops without loading coils resulted in physical dimensions larger than the 20-meter loops. This accounts for the 15-meter loops around the outside of the antenna.

Construction

The miniquad was constructed on bamboo spreaders, supported as shown in Fig. 1. The 20-meter loading coils were made of 17½ turns of #14 AWG copper wire wound on 1½-inch-diameter x 5-inch-long PVC thin-wall plastic tubing. The coils were spaced as shown in Fig. 2. Fig. 1 shows details of the boom-to-rotor attachment. The coils and spreaders were given two coats of polyurethane-type varnish. The 8½′ boom was made from 2-inch-diameter aluminum irrigation pipe. The guy wires supporting the mast were attached directly to the TV rotor because the lower half of the quad extends only 3 feet below the boom (compared with 9 feet for the full-size quad). This made the installation much more rigid. At every 5 feet, the guy wires were cut and egg insulators attached.

Preliminary antenna tuning was done on the ground by placing the boom on top of an 8-foot stepladder. The coil of a dip meter was



A close-up photo showing the method of attaching the boom to the rotor.

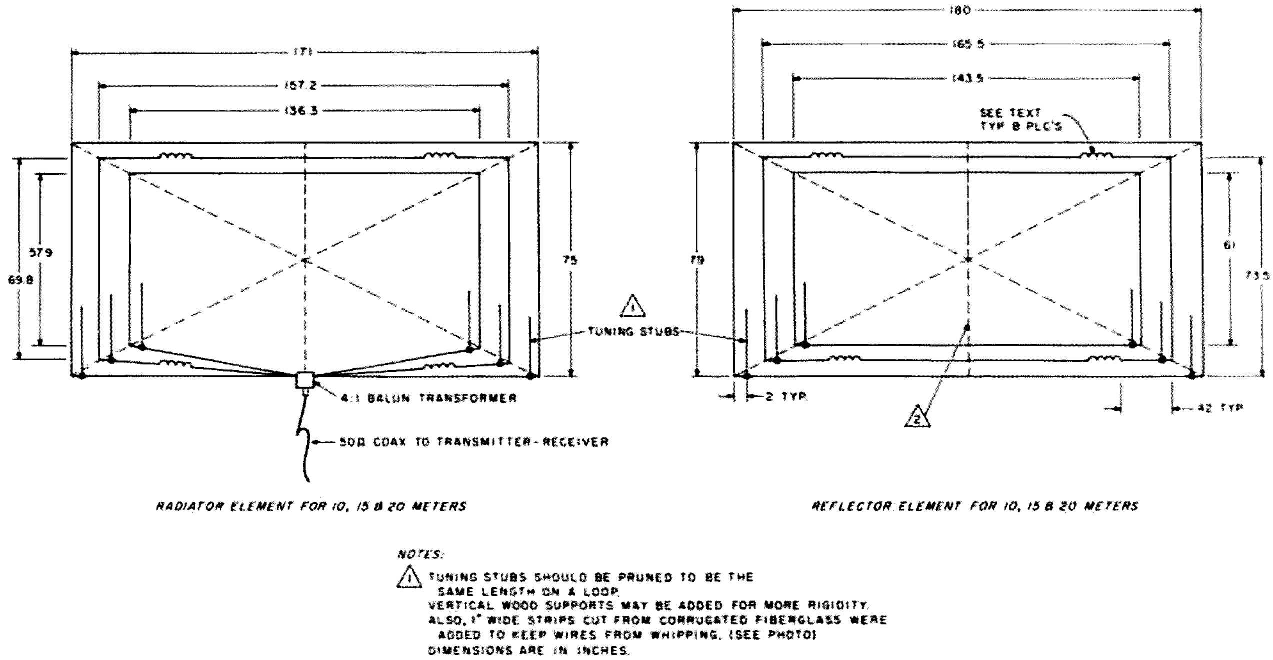


Fig. 2. Radiator element for 10-, 15-, and 20-meter bands. If a director element is desired, make dimensions 5% less than radiator and space the director .125 x wavelength (in meters) in front of the radiator element.

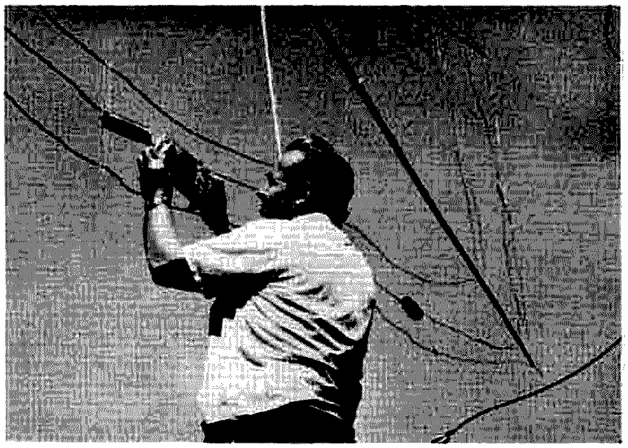
placed inside one of the 20-meter loading coils and the length of the tuning stubs adjusted for the proper resonant frequency. Since raising the antenna from ground level to the top of the TV mast raises the resonant frequency, resonance on the ground was adjusted about 100 kHz lower than that required in the air.

After installing the antenna on the mast, fine tuning of the radiator was accomplished by checking the swr in the ham shack. Additional pruning of the stubs was required to bring the lowest swr reading into the desired portion of the 20-meter band. The reflector was pruned using the dip meter reading 5 percent lower than the final radiator dip reading. For example, if the 20-meter radiator is tuned to 14.2 MHz, then the reflector should be tuned to 14.2 x .95 = 13.49 MHz. All fine tuning was done with the mast telescoped down.



Here the antenna tuning is being checked after two years of operation, using a home-brew dip meter-transistor checker.

With the 8-foot stepladder on the roof and the boom U-bolts loose, I was able to rotate the antenna vertically and reach the stubs for pruning.

Tuning the 20-meter band only was easy. After installing the other two bands, however, interaction between bands made it necessary to repeat the pruning process. This was the most critical part of the whole project, but you will find that a few extra trips between the roof and the shack to recheck tuning on each band will be well worth the extra effort. You'll have an antenna that will provide many hours of good DXing and solid contacts. Also, when your neighbors see you climb up your roof a number of times and see you clip only an inch or two of wire from your antenna, they will *know* you are crazy!

If, as I did, you have problems getting enough coupling with your dip meter to the 10- and 15-meter loops (no loading coils on these bands for coupling), try the following:

1) For the radiator, clip a ½"-diameter turn of wire across the coax terminals at the bottom of the loop. Couple the dip meter into the added turn.

2) For the reflector, put a ½"-diameter twist in the bottom center of the loop. Tune the reflector 5 percent lower in frequency, as noted above.

The Proof is in the Pudding

Having previously used an allband inverted vee antenna, I was amazed at the superior performance of the miniquad. After completion of the 20-meter portion of the miniquad, it was installed and a quickie evaluation was made when 20 meters appeared dead on the inverted vee. With the quad pointed south, some South American stations were picked up, including an ice-breaker running traffic to the States from the Wadell Sea. Then, rotating the quad northwest, a QSO was made with a station in Tokyo, Japan. I couldn't hear them on the inverted vee, and if you can't hear

them, you can't work them!

The next day, using the miniquad, I answered a "CQ". Running barefoot (150 Watts), a fine 20-minute QSO was made with OK1TA in Czechoslovakia. (Later I received a fine QSL card and letter.) At the conclusion of the QSO, there was a big pile-up, mostly east coast stations trying to work him! I was impressed, as this was my first European contact as a ham! After adding the 10- and 15-meter elements, results were equally satisfying. Many contacts have since been made around the world, on all three bands.

The antenna has been in service for two years now, and is still performing as well as it did originally. The two coats of varnish are starting to show some deterioration from exposure to the intense radiation of the southern California sun, however, and while I don't have the problem of ice as do my eastern counterparts, we do have Santa Ana (devil) winds. These winds can reach 70 miles per hour and higher. At times, they have really made the antenna dance a jig, but it has stood up well.

I think that for a cheap, compact, directional, gain antenna, this one is hard to beat, since much of it can be built with bits of material you may have lying around your QTH! ■

Bargains in Remote Antenna Switches

—watch for these surplus gems

Carl C. Drumeller W5JJ
5824 NW 58 St.
Warr Acres OK 73122

Remote antenna switching can be a highly desired feature in one's station. The high cost, up to $125.00 or over, deters many amateurs from giving it serious consideration. The answer? Keep an eye on military surplus outlets and on swapfests.

The choicest item to look for is the Thompson Products, Inc., type 10281 coaxial switch. It'll mount outdoors, antenna level or wherever you elect to put it; it operates on direct current at a low voltage. Although rated at 24 volts, it'll function at as low as 10 volts. Its control requires a 5-wire cable, as it involves positive selection of the desired switching function . . . no stopping at a wrong position. It provides for selection of three antennas from one incoming cable. The cable connectors are of the type N variety, which means they can be weatherproof, quite unlike the UHF type often used for outdoor applications. The control function connector involves a standard type of Amphenol, one readily available.

Why is this "choice"? Well, for one thing, there are 12 steps in its transfer action. These provide for such operations as grounding the unused antennas, opening all incoming circuits, grounding all incoming circuits, and then connecting through the selected antenna. One purpose of these operations is to ensure that all accumulated electrostatic charges are drained off an antenna before it is shifted into service. Thoughtful, huh? Note that when one antenna is in use, the other two are not gounded. Some may find this preferable, some may not. But with 12 steps in the operation, only one action is needed. You just close a switch placing the direct current voltage between the common and the wire controlling the antenna outlet you want. The interior stepping motor does the rest! No continuing current is required to hold the desired selection. The circuit is broken when the stepping motor reaches the selected segment. The switch you used can be left closed to provide an indication of the antenna in use.

There's another surplus relay worth looking for, too. Like the first mentioned, it's suited to outdoor mounting, has type N rf connectors and an Amphenol control connector, and operates on low voltage direct current. It, however, is only a single-pole double-throw coaxial switch. Although rated at 24 volts, my advice is to supply it with no less than 28 volts. I've had one stick between antennas when the controlling voltage was less . . . a highly undesirable condition, as the controlling circuit is broken and the relay must be disassembled in order to move it on to a position that permits the controlling circuit to function!

This second item is made by General Communications Co., and is the model 2N18ORC-5 rf coax switch. It appears to be a bit more readily available than the Thompson Products relay.

Either of these two devices can be an asset to an amateur station. Neither should cost the "arm and a leg" asked for commercial relays that are no better and probably not as good. If you see one, grab it. ■

A No-Nonsense Operating Table

—basically, it's a flat surface on legs

Ken Anderson
Age 11
3005 W. 19th
Lawrence KS 66044

To build this table, you will need 8 or 9 two-by-fours. Check to see if some are crooked. If some are, do not use them; this is important to your table. Using the two-by-fours, cut four pieces 27 inches long; these will be the legs. For the sides, cut out two 72-inch pieces. For the leg supports, cut four pieces 24.5 inches long. For the footrest support, cut out a 72-inch piece.

Now you are ready to begin the main part of the table. Take two of the legs and two of the supports and bolt them together as shown in Fig. 1. Do the same to the other legs and leg supports. Now get a piece of particle board 72 inches by 28 inches, but don't put it on until the end. Have someone holding one of the leg pieces while you are bolting the footrest support to the middle of the bottom leg support. Then do the same to the other side. Now nail the sides on and screw the top on as shown in Figs. 2 and 3. If you want your table to be very flat on top, countersink some flathead screws. To cover up the screws, use wood putty.

Tools and materials needed include: drill, hammer, right angle, power saw, wrench, 14 bolts, 8 nails, 8 or 9 two-by-fours, 1 piece of particle board 72 inches by 28 inches. ■

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

FORT MYERS FL
NOV 3-4

The Fort Myers Amateur Radio Club and the ARRL will host Ham-arama '79 on November 3-4, 1979, at the Ramada Inn, Fort Myers Florida. Featured will be dealer displays, educational forums, and an outdoor flea market. Registration is $3.00 per person. For information contact K4VGN at (813)-334-6190, or WD4ERA (813)-332-1825.

HICKSVILLE OH
NOV 4

The Defiance County Amateur Radio Club is sponsoring its 2nd annual hamfest on Sunday, November 4, 1979, from 8:00 am until 4:00 pm at the Defiance County Fair Grounds, Hicksville, Ohio. Tickets are $1.50 in advance and $2.00 at the door. Talk-in on 146.52 and the club repeater, 147.69/.09.

WEST MONROE LA
NOV 11

The Twin City Ham Club will sponsor North Louisiana's annual "Hamfest" on Sunday, November 11, 1979, from 8:00 am until 3:00 pm at the West Monroe Civic Center, North 7th Street and Ridge Avenue, West Monroe, Louisiana. Tickets may be purchased at the door or in advance for admission and for the prize drawings. Featured will be swap tables for buying, selling, or trading amateur and related equipment, displays of new radio and electronic equipment, information on becoming an amateur operator, and prizes. Everyone is invited. The building is heated and cooled for your comfort. Talk-in on .25/.85, .52/.52, and 3910.

FRAMINGHAM MA
NOV 11

The Framingham Amateur Radio Association will hold its annual fall flea market on Sunday, November 11, 1979, from 10:00 am to 3:00 pm at the Framingham Police Station Drill Shed, Framingham, Massachusetts. Admission is $1.00 for the general public and $5.00 per table for sellers. Sellers are advised to pre-register as tables are limited! Talk-in on .75/.15 and .52. For information, contact Ron Egalka K1YHM, FARA, PO Box 3005, Saxonville MA 01701, or phone (617)-877-4520.

CLEARWATER FL
NOV 17-18

The Florida State ARRL convention will take place on November 17-18 at the Sheraton Sand Key Hotel on Clearwater Beach, Clearwater, Florida. An Icom 701 HF station is the main door prize. The latest update on WARC proceedings is just one of the interesting forums we have scheduled. FCC exams will be given on Saturday at 9:00 am. Please send 610s to the Tampa office by November 9. There will be ladies' events both days, with a luncheon and style show on Sunday. Tickets are $5, which includes a Tappan microwave oven as first prize. The QCWA Gator Chapter will host the Saturday luncheon, with all hams and guests welcome, too; tickets are $6. Saturday evening banquet tickets are $9. Swap tables are $10 for both days—no one-day tables, all advance sold. There should be plenty of parking with courtesy buses running on demand for the duration of the hamfest. We have arranged for special room rates at $30 double, per day, with each extra person $4 and kids under 18 free. Hamfest donation is $3; each advance ticket includes two free prize tickets. Talk-in on .37/.97 and 223.34/224.94. Please make all reservations through and checks payable to: FGCARC (Florida Gulf Coast Amateur Radio Council, Inc.), PO Box 157, Clearwater FL 33517. For ham convention and hotel reservations, phone (813)-461-HAMS.

MASSILLON OH
NOV 18

The 22nd annual auction, Auctionfest '79, sponsored by the Massillon ARC, will be held on November 18, 1979, from 8:00 am until 5:00 pm at the Massillon Knights of Columbus Hall, Massillon, Ohio. The flea market opens at 8:00 am, with auction action at 11:00 am. There will be prizes and displays. Talk-in on 146.52 simplex. Tickets are $2.00 in advance; table reservations are $1.00 per table. For further info, write to Joe Turkal K8EKG, 1234 Concord NW, Massillon OH 44646.

FORT WAYNE IN
NOV 18

The Allen County Amateur Radio Technical Society will hold its 7th annual hamfest on Sunday, November 18, 1979, at the Allen County Memorial Coliseum on US 30, Fort Wayne, Indiana. This will be an all-indoor exhibition and giant flea market. There will be many prizes, including a TS-120/PS and an FT-207R. Admission is $3.00 at the door and $2.50 in advance. Children under 12 are free. A 3' × 8' table rental will cost $4.00. Talk-in on 146.28/.88, 147.255/.855 and 146.52. Hamfest fun starts Saturday night at the Fort Wayne Radio

RIPPED OFF?

If you have a serious problem with a ham firm, send them a letter with all the facts in detail, plainly and simply . . . and send a copy to Wayne Green W2NSD/1, c/o 73 MAGAZINE. 73 protects its readers more than any other magazine.

Ham Help

I am a 54-year-old Novice and have purchased an old Harvey Wells Bandmaster Senior, model TBS 50-C. I would appreciate hearing from anyone who may have the operating instructions for it. I would be most happy to pay for them or have them copied and returned to you.

Al Santi
PO Box 946
Bend OR 97701

I need a schematic and information on an INOUE model FDFM-2 2-meter 6-channel rig. I will copy and return or pay a reasonable price for a copy.

Harold S. Roth WØLFH
602 W. Nebraska
Algona IA 50511

I'm looking for someone competent to repair a Hallicrafters HT-37 that has a poor CW note.

Roy A. Holman WD9GXZ
2124 East Kansas Street
Springfield IL 62703

Club's Saturday Night Funfest. There will be prizes, hot and cold snacks, a cash bar, information, displays, and mini-forums from 7:00 pm to 11:00 pm, Saturday, November 17, at the Holiday Inn, 3330 West California Road. There will be displays by 10-X, ARES, ACARTS, FWDXA, and others, as well as mini-forums on NBVM, DX, Field Day, and more. Funfest tickets (include food and raffle) are $2.00 in advance, $2.50 at the door. For reservations, write to ACARTS, PO Box 342, Fort Wayne IN 46801. For confirmation, include an SASE. Tables are available for setup at 7:00 am.

COLUMBIA MD
NOV 25

The Columbia Amateur Radio Association will hold its 3rd annual Hamfest on Sunday, November 25, 1979, at the Ellicott City National Guard Armory, just east of Rte. 29 on Rte. 103, Columbia, Maryland. Doors will open at 6:00 am for exhibitors and 8:00 am for the general public. Admission is $2.00; tables are $5.00. There will be no tailgating. Food will be available and prizes will be awarded. Talk-in on 147.735/.135, 146.16/.76, and 146.52/.52. For table reservations and information, write Sue Crawford N3SC, 6880 Mink Hollow Road, Highland MD 20777.

OAK PARK MI
NOV 25

The Oak Park High School Electronics Club will present a Swap 'n Shop on Sunday, November 25, 1979, at Oak Park High School, 13701 Oak Park Blvd., Oak Park, Michigan. Donation is $1.50 and tables are $2.50. There will be refreshments and door prizes available.

LANCASTER PA
FEB 24

The Lancaster Hamfest will be held on February 24, 1980, at the Guernsey Pavilion, located at the intersection of Rtes. 30 and 896, east of Lancaster, Pennsylvania. General admission is $3.00, except children and XYLs. Doors will open at 8:00 am. All inside spaces are available by advance registration only and are $3.00 each for an 8-foot space, which includes a table. There will be free tailgating in a specified area outside, if the weather permits. There will be a two-hour Dutch Country tour by an advance registration of $4.00. Food will be served at the hamfest. Also, there are excellent restaurants and accommodations in the area. Talk-in on .01/.61. For information, write Sercom, Box 6082, Rohrerstown PA 17603.

STERLING IL
MAR 9

The Sterling-Rock Falls Amateur Radio Society will hold its 20th annual hamfest on Sunday, March 9, 1980, at Sterling High School field house, 1608 4th Ave., Sterling, Illinois.

✓ Reader Service—see page 243

LETTERS

from page 16

crossmode, regenerated-teletype" contact ever. Not only were KØJUY and WBØSAX glad to get a confirming QSL from Tony, but Tony is still bragging about his accomplishment of working Iowa RTTY on "two meters"!

For a brief while, our unique teletype repeater system actually had begun experimenting with a secondary 6-meter FM input at 52.700 into the two-meter system for the purpose of auxiliary input, extension of range, and full-duplex teletype. Unfortunately, the idea did not get much further due to conflicting club problems.

Crossbanding, if handled intelligently and not just to add another feature-type thing, can be a unique, rewarding, and usable addition to the VHF ham's communication system.

Keep up the good work. We need more RTTY articles and more SSTV articles, too!

Michael W. Stone WBØQCD
Lowden IA

WANE

Congratulations to Wayne on bagging all the New England states on 10 GHz. I guess that makes him the first 3-cm WANE.

John A. Carroll
Bedford MA

CLUB DISCOUNT

It has come to our attention that numerous amateur radio clubs and organizations are conducting CW training programs and are always seeking new and better teaching aids. In order to assist them, Xitex Corporation, Dallas, Texas, is offering a new Morse code "transceiver" at a substantially-reduced club price. The unit connects to any TTY or video terminal (Xitex SKT-100) and can be an extremely useful tool for improving both sending and copying skills.

For further details on how to apply for this limited club discount price, write or call me.

Steve Kriss
Xitex Corporation
9861 Chartwell Dr.
Dallas TX 75243
(214)-349-2490

DEPLORABLE

During the recent passing of hurricane David along the east coast, I was tuned to 14.325 where the Hurricane Watch Net was operating. I have never heard such deplorable conduct by amateurs. There was deliberate jamming, foul language, and amateurs operating so close to the frequency (some I know were running excessive power) that it made copy almost impossible.

At one time, there were two ships in trouble. The Coast Guard was attempting to get a fix on their positions through the amateur frequencies, but, due to the deliberate jamming by these individuals, it was impossible. This alone is enough to turn one that is interested in amateur radio against it.

To think that some amateurs would stoop this low, knowing human lives are involved, is disgusting. I hope that the FCC was able to apprehend some of these individuals and that their licenses are revoked permanently.

Henry Ponder KA4DCQ
Lawndale NC

THE END

I have been monitoring the Hurricane Watch Net on 14.325 for the past 24 hours. At the present time, hurricane David is off the Florida coast and hurricane Frederic is over Barbuda. The net has been operating for the past 7 days. What I heard sounded more like CB (an insult to the Citizens Radio Service). Given the incredible number of lids, SOSers, tuners, etc., on the net frequency (sounded like the majority of US stations), Lynne WA1KKP did a very commendable job. If I were net control, I would have asked for a loaded shotgun. US amateurs make communications almost impossible.

If any of the delegates who will be at the upcoming WARC were listening to this mess, we can kiss each and every amateur band good-bye now! I have been licensed for four years and I have never heard such inconsiderate operators. I refuse to operate under these conditions, so all of my activity was on the Army MARS bands.

This hurricane was not only a disaster for the Caribbean, but also a disaster for amateur radio. I think that this may be *the end*. I will miss hamming very much. To all the operators in other countries, I would like to apologize on behalf of *all* the American hams, the majority of whom are very fine people. It's a shame that a minority can ruin it for us all. Oh well, I guess there's still microcomputing.

Keep up the good work, Wayne, and if you can get us out of this mess, you should be elected President. 73.

Christopher R. Wiener
N2CR/AND1DY
Tenafly NJ

BAD TASTE

I read with deep concern the article on receiving MDS channels in the August, '79, issue of *73 Magazine*. Just where do we draw the line as responsible American citizens, let alone those who have been granted the privilege of operating amateur radio stations in this country?

Why is it that your magazine chose to use an article detailing how to, in effect, *steal* a television signal? The reason these frequencies are not included in home TV receivers is because they are not intended to be received by home receivers.

Instead of printing articles such as this, why not exercise some discretion? You should have printed a fiery reprimand concerning the irresponsible use of technology by so-called "amateurs" who amount to nothing more than "justified" petty thieves. *73 Magazine* should set an example and give us leadership. Amateurs all over the world are crying out for newsworthy PR concerning the reality of service amateur radio affords to the community and to the world. Printing an article such as this is just plain bad taste and shows the deep spiritual need for a reawakening of the American spirit on which this country was founded.

Dale Alan Richman W4NHM
Sevierville TN

SOUR GRAPES

Your response to Vic Clark K4KFC (Letters, August, 1979) was pure sour grapes. Some of the criticisms you have for the ARRL may be well-founded, but you must admit that the League has been the only long-term, stable representative of the radio amateur. Your efforts on behalf of hams can at best be described as mercurial. It's probably more accurate to call them erratic. On the other hand, your criticism of the ARRL has been unflagging.

You are right in saying that the League has led too little, but you have not led either. Too many of us, like you, only react to situations, rather than create them. I, for one, am glad to see the ARRL considering the long-range problems and opportunities of amateur radio, and I'm glad that they are considering the views of all hams.

David Swierenga K4FNE
Fairfax VA

DEAR OM/YL

First, I would like to say that I enjoy reading *73*. My husband and I are both Novices and are working toward our Generals. Our antenna is a five-band dipole worked out from an article in one of your magazines.

However, I do have one thing that bothers me. I keep getting information on subscriptions to your magazine addressed to Dear OM. This particular form of salutation annoys me very much. It is not that I am a woman's libber in the full sense of the word, but I am proud that I am a woman and like to have it acknowledged. I know that this is a standard form of salutation in ham parlance, but it certainly doesn't apply to all hams. Hope that something can be done about this.

Clare N. White WB6WSP
Sonora CA

OK! You win! All reference by 73 in the future will include Young Ladies. How about "Dear OM/YL"?—Robert R. LaPointe, Marketing Director.

Ham Help

I'm looking for a schematic for an ARC-27. Can anyone out there help? I'll be glad to pay a reasonable price for one. Thanks.

Ron Johnson WA5RON
3524 Greystone, #194
Austin TX 78731

I am in need of a schematic and operating manual for a Knight-kit T-60 transmitter. I would be more than happy to pay back any reasonable copying and mailing costs. Any help will be greatly appreciated.

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. if it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

Review

CONFIDENTIAL FREQUENCY LIST
by Oliver P. Ferrell,
4th Edition, 1979, 104 pages,
6-1/8" × 9", paper, $6.95,
distributed by
Gilfer Associates, Inc.,
PO Box 239, 52 Park Ave.,
Park Ridge NJ 07656

Have you ever wanted to listen to NASA, INTERPOL, the Russian Navy, the US Coast Guard, or the Rumanian Embassy in Washington? Or have you heard stations with strange callsigns like XSV and KKN50 and wondered just who they were? Perhaps you're just curious about "what's out there" other than hams, broadcast, and CB. If any of these descriptions fit you, then you'll probably be interested in this book.

The *Confidential Frequency List* (*CFL*), now in its fourth edition, lists hundreds of stations in ascending order of frequency from 4001 to 25590 kHz. Included, in most cases, are the frequency, mode, callsign, location, type of service, and power. Many entries also have remarks which tell the listener more specifically what to expect on a frequency—aircraft in Southeast Asia and western Australia, weather reports, telephone conversations, etc.

Previous editions of the *CFL* were arranged by type of service—a section for INTERPOL, one for broadcast feeders, one for VOLMET (aviation weather), etc. That was convenient for eavesdropping on a particular service or station. This new edition, listed by frequency, is very good for identifying "weird" stations heard. It's a bit difficult, though, to find (for example) all the frequencies for NOJ (Coast Guard Radio, Kodiak, Alaska) or NASA. Perhaps the future editions of *CFL* will have some type of cross index to eliminate this problem. One further suggestion for future editions would be to include a wider range of frequencies. (There are interesting stations all the way down to about 10 kHz. Nationwide VHF frequencies would be of interest to the many owners of scanning VHF receivers.)

These few criticisms are minor. A book can't be all things to all people. As it is, the *CFL* is a most valuable resource for anyone with access to a general-coverage radio who wonders, "What's going on?"

Readers should note the author's admonition that the "confidential" part of the title is no joke. It refers to the secrecy provision of the Communications Act which prohibits the disclosure of the content of any non-ham and non-broadcast radio transmission.

Ham Help

I need information on converting a Collins R-390A to product detection or installing a product detector. Thanks.

George Shira WD4BUM
RT. #7, Box 101-I
Anderson SC 29624

I have been trying to find some parts for an AN/ARR-52 Radio Receiver. I have been able to find everything I need except for the channel selector control box (model C-3109/ARR-52) and the signal level meter box (model SB-1084/ARR-52).

It's a little slow changing channels with a screwdriver. Does anyone know where I might find these two items? Thanks.

Microcomputer Interfacing

from page 28

NXTKEY. In ten milliseconds, the 8080 returns from DELAY, which is a sufficient period of time to debounce the switch closure. The 8080 now has to determine which key in column A is pressed. It does this by rotating to the right into the carry the word that was previously input. If a logic one is rotated into the carry, the JNC to RELESE is not executed. Instead, the content of the D register is increased by four. By jumping back to AGAIN, the 8080 can rotate another bit of the A register into the carry. When a logic zero is rotated into the carry, the unique code for the key that is pressed is in the D register, so the jump to RELESE is executed by the 8080.

```
/THIS SUBROUTINE SCANS A MATRIX KEYBOARD
/THAT IS ARRANGED AS FOUR ROWS OF FOUR KEYS,
/A 4X4 KEY MATRIX.  IN ADDITION, INSTRUCTIONS
/HAVE BEEN ADDED TO THE SUBROUTINE TO DEBOUNCE

        RET     /AND RETURN WITH THE KEY CODE IN D
```

Fig. 4. A subroutine that scans the 16-key keyboard.

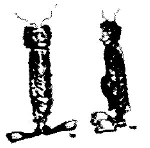
The 8080 now waits for the key to be released, at which time the DELAY subroutine is called again. This causes the key opening to be debounced. The RET instruction at the end of the DELAY causes the 8080 to return to the program that called KEYSCN. When it does, the key code is in the D register.

As an example, let us assume that the nine key is pressed. The 8080 loads the D register with three and the B register with 11111110. The content of the B register is output to the keyboard and is then rotated to 11111101. The row data from the keyboard is then input, but since no key in column A is pressed, the A register contains 017 after the ANI instruction is executed. Therefore, the content of the D register is decremented from three to two and the 8080 jumps back to NXTGRP so that the B column can be tested. When the 8080 executes the instruction at NXTGRP this time, a 11111101 is output to the keyboard, but since no keys in the B *column are* pressed, the 8080 inputs a 017. Because of this, the content of the D register is decremented from two to one, and since this value is not equal to 377, the 8080 jumps back to NXTGRP.

The 8080 now tests the C column by latching out a 11111011 to the keyboard interface. Since a key in the C column is pressed (the 9 key), the A register will contain 11111011 when the IN 000 instruction is executed. The ANI 017 instruction sets bits D7 through D4 to zero, so the A register contains 00001011. Since this value is not equal to 017, the 8080 executes the jump to NXTKEY. The DELAY subroutine is then called, so that the key closure is debounced. The A register still contains 00001011, so a logic one is rotated into the carry when the RRC instruction is executed the first time. This means that the JNC to RELESE is not executed. Instead, four is added to the content of the D register (one) and the result (five) is saved in the D register. By jumping back to AGAIN, the 8080 rotates the 00000101 once to the right, and again, a logic one is rotated into the carry. As before, the JNC to RELESE is not executed, so four is added to the content of the D register (five) and the result (octal 011, decimal 9) is saved in the D register. When the 8080 jumps to AGAIN this time, the 00000010 in the A register is rotated to 00000001, and a logic zero is rotated into the carry. This means that the JNC to RELESE is executed. Once the 9 key is released, the DELAY instructions are executed, and the 8080 returns from the subroutine with the code for the nine key (octal 011, decimal 9) in the D register.

Surprisingly enough, no additional software instructions have to be added to the subroutine in Fig. 4 for the 8080 to scan and encode a 64-key keyboard! In fact, only four immediate data bytes have to be changed. However, the interface would have to consist of an eight-bit output port (so that a test pattern for eight columns of keys could be output) and an eight-bit input port (because there are eight keys in each column). This means that the keyboard consists of eight columns, each containing eight keys. Note that the software in Fig. 4 does not produce ASCII values for the key closures. However, this could be done very easily, simply by using a look-up table that contains 64 entries.

As you have seen, key closures can be encoded by means of hardware or software. A number of integrated circuit manufacturers have keyboard-encoder integrated circuits available which can be used very easily and with a minimum of software. However, they may be too expensive or not flexible enough for your needs. By using a scanned keyboard, the interface electronics are kept to a minimum. However, a long and complex subroutine must now be used to debounce and encode the key closures. This subroutine consists of 38 instructions and requires 67 memory locations for storage. If a look-up table is used to convert the key codes to ASCII values, an additional 72 memory locations will be required to store the look-up table and some additional assembly language instructions.



Ham Help

I would like to get in touch with hams around the world who are under the age of 20 and who are interested in joining the Young Amateurs World Net (YAWN). Please send an SASE for info.

Stephen V. Genusa WD5EAE

RTTY Loop

from page 20

for nominal amounts from several of the teletype suppliers mentioned in the column a few months back or from many *73* advertisers.

If only a few symbols are to be changed (say you want to change from press to communications), replacement type pallets also are available. These are simply soldered onto the end of the type bar after the old pallet is removed by desoldering. It takes only a few minutes, and the procedure is painless unless you try to hold the type bar while soldering.

Turning to other matters, Bill Taylor K8TBW writes describing a nice RTTY setup including the Microlog equipment and Drake line. Bill is trying to use the Heath SB-610 monitor scope with the station, but has a problem. The scope requires the mark and space detector outputs, and the Microlog unit does not provide them. He wonders if there is any way to use the 610 with audio input and still get an X or + pattern.

I don't know, Bill. It seems to me that you would have to build the front end of a demodulator to feed the thing. Basically, the limiter and mark/space filters would be needed to get differential outputs. That is really not all that much, but it seems like a waste. If any readers have information on such a wedding, I would be interested in passing it along to Bill and others.

Have received a snazzy publication from the Stark County RTTY Group called *Watts Happening*. Passed along by Joseph Ebner WB8RVM, it points to an active group out there in Massillon, Ohio, and I am sure that they would appreciate hearing from hams in the area who are interested in RTTY.

As of this writing, no word has been received on Teleprinter Art, Ltd., as reported in last month's "RTTY Loop." A communication to the firm has been without response, and several more individuals have reported to me that they have received less than satisfactory service from the company. I urge all readers to be cautious in their dealings with all mail-order firms.

Leaky Lines

from page 24

prices, I don't think that this amount would even cover the cost of the receiver alone! The strange thing about this is that this particular design has not been altered in any significant way since I bought mine. Even more important, it's practically impossible to find reliable sources for quality vacuum tubes. A friend told me that he put forty 12AT7s on his tube checker in an attempt to find a matched pair and no two even came close in transconductance figures. Is it any wonder that hams are switching to more modern equipment?

As far as I know, there are only two major American companies producing gear that is competitive with the imported equipment. All others seem to have fallen by the wayside. Kenwood, Yaesu, Icom, Trio, Tempo . . . these are the names that show up nowadays, and I must confess that they sound at least as good as the best old stuff, and usually a good deal cleaner.

This makes me laugh, really. A fellow I know only slightly gave me a bad going over for driving a foreign car. He said that buying an export is practically treasonous in these times. But about six weeks later, he showed up on 20 meters with a brand new Icom 701 with all the goodies to match!

There's nothing like a little consistency . . . right?

Looking West

from page 18

Now, then, New York and Los Angeles, in our example, are terminal cities or terminal ports. Since in the southwest repeating devices sit atop high mountains, fewer hops are necessary than in areas where such elevation and line-of-sight characteristics are not attainable. Out here, the average repeater has saturated coverage for about 150 miles from a good mountaintop and peripheral coverage for another 50 to 70 miles. A similar repeater atop a building in an eastern or midwestern city might cover 50 to 70 miles saturated and another 15 or so in peripheral. Remember, we are discussing ideal average systems and not the occasional super system that, through some odd circumstance, is able to do what others cannot. Let's go ahead with these figures as our reference. Then, in like manner, we can apply a similar program to the interlinking portion of our intertie.

Again, using 220 MHz as our intertie band and considering normal band conditions most of the time, it should be possible to accomplish between 150- to 275-mile minimum hops, using nominal power and directional antennas at any given linking site. If all things were equal (and due to the variations in terrain they are not), we would come up with an approximate figure of 20 linking sites, giving us coast-to-coast communication between two major American cities with a large two-meter FM population. If we worked with a 275-mile link figure, the number of linking sites would be down to about a dozen. This might be further enhanced if we were to borrow some weak-signal technology from experts in this field and utilize SSB rather than FM for the modulation system on our interlink channels. This would be the ideal situation. However, in real life I suspect that it would probably necessitate more on the order of 30 links to accomplish such a goal. If that sounds like a lot, it is, in reality, less than 1% of the total number of two-meter open systems operational at this time. I think that I am safe in assuming that there are at least 30 repeater owners out there who might find a project such as this an exciting challenge. Making it happen requires only a bit of "bread," some well-thought-out technology, and believing in the motto, "Yes, I can!"

As I write this, I can imagine some of you asking, "How will it be policed? What if it gets jammed—what then?" Or, "Nobody will be able to use it; it will be a madhouse." Things like this can happen and, at least at the outset, I would expect them to. However, if we spend our lives worrying about the "might" and the "maybe," we will live to see nothing of consequence accomplished. Everything in life has an element of risk. There comes a time in any person's life when he must look in the mirror and decide if he is a man or a mouse. Is he willing to look forward to and participate in the future, or does he take the ostrich approach? Sure, we have problems, both technological and sociological, but to run and hide our heads in the sand will accomplish nothing. We amateurs have faced problems before and have whipped them before. Why should this situation be different?

CROSSBAND REPEATER DEPARTMENT

Earlier this month, I spent about a half hour on the telephone with Wayne, and one of the subjects we discussed was crossband repeaters. This idea is not new. In fact, crossband repeaters were in vogue prior to the "18803" dark ages. Lately they are coming back, along with crossband/cross-mode repeaters, to allband HF SSB. I can see only one drawback to such crossband devices: the necessity of carrying two radios wherever one goes. Usually this is not a problem at one's base station. In fact, some of the newest of the five-band HF transceivers feature an FM-mode position. Yaesu and others have pioneered this knowing full well that FM capability, with its intended use on ten meters, makes for a more useful all-around transceiver package. This is fine for home, but a mobile installation is a different story, especially as today's "mobiles" are a lot more cramped for space than were their cousins of a few years back. I drive a compact car myself these days, and trying to fit two adults, radios for both two meters and 220 MHz, and associated tone-pads into the front seat is a bit of a chore. Even if I were to trunk-mount something like a Motrac, there would be little if any room for a control head.

If you are like most amateurs I know, you will want to have both bands with you. For example, most of my operating out here is on 220 MHz. Most of my two-meter operating is done through a remote base accessed from 220 MHz. However, once out of range of the 220 remote, I rely heavily on my Icom 22A and/or Clegg FM-27B, depending on which one happens to be in the car at the moment. A solution to this dilemma may be in using a highly modified mini-CB radio as the ten-meter mobile station. Such radios can usually be had for a song at local swapmeets and CB breaks. With a bit of

time and correct technology, such radios might be excellent ten-meter FM performers. Also, who says that the ten-meter portion of such systems must be FM? Judging by the number of CB-to-ten-meter conversions appearing in *73* and elsewhere, it might be wise to standardize on good old "ancient modulation" for ten-meter crossband operations. This would open things up to many more people. Not everyone is prepared to pay a lot of money to try something new, but they might spend a few bucks to get their feet wet. QRP AM on ten meters blends nicely with two-to-ten crossband operation and, while it cannot match the fade margin afforded by FM operation, it's a nice, inexpensive way to begin. Also, it will fit in the tiniest of vehicles along with the two-meter rig.

If you deal with a crossband repeater in the purest sense (in a classic repeater configuration), then you will require two radios in order to both talk and listen. A true crossband repeater is one that listens on a given band and re-transmits on another. However, there is a better way of doing things, and this is known out west as "remote-base configuration."

We have discussed remote-base operation, but a quick review might be in order. First, the accepted full designator for a remote base is (get ready for this) "the individually owned and operated, advanced format, remotely-controlled amateur base station radio." I prefer the simple term "remote." A classic remote is one in which the base station is at some good site and is controlled by some form of auxiliary intertie. This can be a phone line, direct hard-wire, or a radio link above 220 MHz. In most cases, a remote serves the dual function of repeater (or autopatch repeater) and interlink to other bands. Until recently, most remotes restricted operation to such simplex channels as the national remote-base intertie channel of 146.46 on two meters, along with such others as 146.94, 52.525, and 29.6, all of the latter being nationally accepted simplex allocations.

Frequency synthesis revolutionized not only 2m FM operation, but 2m remote downlink use as well. Many older remotes opted for synthesis over crystal control, and virtually every new remote I run into is fully synthesized on its two-meter downlinks.

It's not uncommon around here to work someone on a two-meter repeater which, in turn, is operating from an area removed from that repeater's normal coverage through a remote-base system that can talk to the repeater. Sound confusing? It really isn't. For example, Newhall, California, is an rf pit. Though only a few miles north of Los Angeles, we are surrounded by several kilofeet of mountains, which makes working most Los Angeles repeaters impossible. However, by operating two meters through a remote base (which sees both my QTH and LA's, as it is located atop a 4800-foot hill that overlooks both), I can operate easily through most area systems using only ten Watts and a Ringo on 220 MHz. Without the remote, my access to Los Angeles would be very limited.

There is much to be said for the remote-base concept of crossband operation. First, since all the crossbanding is accomplished at the repeater site itself, the user of this system need carry only one radio. Second, on a remote (or on a private or closed repeater), every system user is automatically a control operator. He has total control over all aspects of a QSO, including the right to "dump it off" should a problem arise with regard to content of communication. The only problem is that there still exist certain prohibitions with regard to controlling a transmitter on *another* band *from* frequencies below 220 MHz. However, this might really encourage 220-MHz repeater expansion. Though by tradition remotes have restricted themselves to small private groups, there is no law that says this must be the case. The recent establishment of 145.60 as a general intertie channel for any 220 repeater wishing to converse with any other 220 repeater is an obvious step in that direction. (145.6 is the correct frequency, rather than the 145.56 which was printed in the August column.) The repeater that initiated it, WA6VNV on Oat Mountain, is a heavily used 220-MHz open-access repeater. They could just as easily have selected a ten-meter frequency, a twenty-meter frequency, and a crossband open remote-base system. It is not a traditional remote base by any means, but nowhere in part 97 does it state that, to be a remote base, a system must be private or restricted access. Most are, for traditional reasons, but as more and more systems join WA6VNV on 145.6 MHz, that tradition, like many others, begins to slip away.

It was suggested several months ago by a "Looking West" reader in Chicago that we should establish a national remote-base intertie channel on ten meters as a common meeting ground for such operations nationwide. At that time, it drew very little response and we let it go. However, the infusion of new crossband VHF relay activity to ten meters brings this concept into the limelight once again. I'd appreciate your input on this subject. A spot lying between the top of the OSCAR downlink and 29.6 has been suggested by some. Maybe you have a better idea. If so, pass it along to the rest of us.

In the meantime, give some serious consideration to the remote-base concept of downlink operation. The user need not buy any extra radio, and only a linking radio is needed at the repeater site. The rewards are great and the cost is minimal.

MORE CHANGES AT WESTLINK DEPARTMENT

I really was not planning to write the following for reasons that will soon become obvious. To some it may sound as though I am tooting my own horn, and that's not true. I am furnishing the following information after having been urged to do so by Wayne, as he convinced me that it is quite newsworthy.

In mid-July, Westlink's network director, Jim Hendershot WA6VQP, asked me if I would consider producing the weekly Westlink Amateur Radio News "QSTs." I told him that I would if I could get both the space to set up a production facility and some assistance. Jim was away on vacation earlier this year, and I filled in for him. During that time, I managed to put together a good news team. It consisted of myself as writer/producer, Bill Orenstein KH6IAF as engineer/production coordinator, and Al Kaul W6RCL and Burt Hicks WB6MQV as anchorpersons. I felt that Bill would be gung-ho. I was right. He was not only elated at the prospect, but even donated office space and much of the production equipment. We then contacted Burt and Al, who were also interested. I spoke with Jim and arranged to take over on the first Sunday of August.

During the transition period, Bill introduced me to a very talented man named Zeke Manners. Zeke is not a ham (not yet), but I think we are getting to him. Zeke is, however, a professional broadcaster who has emceed many radio programs and, thanks to Bill, he agreed to become part of the Westlink news team as well. With this many people involved in Westlink, no one person is totally responsible for the burden of weekly production except for Bill Orenstein, who edits the programs for time and continuity. He does so in the time-honored tradition of hand-cutting the newscast and then transferring it from reel to cart for dissemination. We hope to enlist the aid of at least one other editor to minimize Bill's workload in the future. Keep in mind that this is a voluntary effort on our part, and that each of us has another "real" job. Having produced a fair number of newscasts, I find it hard to believe that any one individual could have done this alone for over two and a half years. Jim did, and he is to be commended for his work.

We are disseminating the newscast in only one way at present. There is no cassette exchange program any longer. Jim discontinued it about six months ago and, after much consideration, we decided not to revive it, though not for the same reasons. For Jim the problem was the time it took for duplication. This would not be a problem for us since we could have utilized high-speed duplication processes and paid for it ourselves. However, there is another reason for not reviving it, and that is the quality of duplication. Bill happens to be an audio engineer by profession, and if there is one thing he knows like the back of his hand, it's tape recording techniques. Bill feels that the main problem with cassette exchange is one of quality control. It seems that no two people ever send the same type or quality of cassettes, and this gives rise to complaints about recording quality. We have therefore elected to utilize an automated telephone system fed from a Collins broadcast cartridge machine. The newscast is first recorded on reel-to-reel tape, then edited by Bill, and finally transferred to cart. It is available from 9:00 pm Sunday to 10:00 pm Wednesday, local Pacific time. The rest of the week, the equipment is tied up in production. Also, the first half hour (9:00 to 9:30 pm Sunday) is reserved for local Los Angeles/San Diego feeds, after which the facilities are available to any repeater or handicapped amateur on a first-come, first-served basis. We will continue this way for the foreseeable future.

Finally, along with those already mentioned, we have added a number of other volunteer correspondents, including Joe Merdler N6AHU (law) and Pat Corrigan KH6DD (Pacific Islands). We also found someone to cover major national conventions and are trying to add a European correspondent from Germany. This is where we currently stand. We admit to being a shoestring operation, trying to do out-of-pocket what other stations do by spending hundreds of thousands of dollars. The amazing thing is that it all seems to be coming together

for us, and this makes me very happy. By the way, if anyone out there happens to have some usable "Fedlilpak" cartridges (large or small) that they are willing to give away, we would be happy to receive them. In fact, it would be much appreciated.

If you would like to get more information on Westlink, have a story you feel is air-worthy, or want to arrange to get the weekly service (which is still free), then drop a note to us at Westlink, 7046 Hollywood Boulevard, Suite 718, Hollywood CA 90028. Also, if you are among those who sent cassette tapes to Jim prior to the discontinuation of the cassette exchange program, they will be returned to you in the near future. We ask that you be patient a bit longer.

Contests

from page 30

QSO points times the IPA countries multiplier.

FREQUENCIES:

SB—3650, 7075, 14295, 21295, 28560 kHz ± 25 kHz.

CW—3575, 7025, 14075, 21075, 28075.

ENTRIES AND AWARDS:

US stations wanting a copy of Sherlock Holmes Award rules, IPARC membership list, contest logs, and results of the 1978 contest should send an SASE with 2 stamps (others send 2 IRCs) to: Vince Gambino WB4QJO, 7606 Kingsbury Rd., Alexandria VA 22310. Any station fulfilling the conditions of the SHA may apply with an application sheet. The approval of 2 licensed amateurs is not necessary when the SHA application is submitted with the contest logs. See SHA rules for more information. The contest winners, the 3 operators with the highest score, receive a certificate and are honored in the Award Chronicle of the International Police Association RC. Logs must be postmarked no later than December 31st and sent to: Bureau National IPA, Section Francaise, CNAS, Mr. Gerard Dupuis, 15 Rue Cambaceres, 75008 Paris, France.

DELAWARE QSO PARTY

Starts: 1700 GMT Saturday, November 10
Ends: 2300 GMT Sunday, November 11

Sponsored by the Delaware Amateur Radio Club (DARC), the contest is open to all amateurs. Non-DE stations work only DE stations.

EXCHANGE:

DE stations send QSO number, RS(T), and DE county. Non-DE stations send QSO number, RS(T), and ARRL section or country.

SCORING:

DE stations score 1 point per QSO and multiply by the total of ARRL sections and countries. Non-DE stations score 5 points per QSO and multiply by the total sum of counties worked per band per mode (max. possible 36, assuming 160 through 10 meters). DE counties = New Castle, Kent, and Sussex.

FREQUENCIES:

CW—60 kHz from low end of each band and 1805.

Phone—1815, 3900, 7275, 14325, 21425, 28560.

Novice—3710, 7120, 21120, 28120.

Check 160 at 0500 GMT and 0600 GMT or make skeds.

ENTRIES:

Send logs by December 15th to: Stephen J. Momot, K2HBP, 14 Balsam Rd., Wilmington DE 19804. If you work all three counties and wish the WDEL Award, include two 15¢ stamps and an address label. Include an SASE for results only.

INTERNATIONAL OK DX CONTEST

Starts: 0000 GMT November 11
Ends: 2400 GMT Sunday, November 11

Participating stations work stations of other countries according to the official DXCC Countries List. Contacts between stations of the same country count as a multiplier but 0 points. Use all amateur bands from 160 through 10 meters on both CW and phone. Cross-band and cross-mode contacts are not valid.

EXCHANGE:

RS(T) and two-digit ITU zone number. Note: ITU zones are different from the ARRL zones. A list and map of the ITU zones are available from the contest sponsors for 2 IRCs.

SCORING:

A station may be worked once per band. A complete exchange of codes counts one point, but three points are earned for a complete contact with a Czechoslovak station. The multiplier is the sum of the ITU zones from all bands. The final score is then the total QSO points times the total multiplier.

ENTRIES:

Categories of participating stations: A) single-operator, all bands; B) single-operator, one band; C) multi-operator, all bands.

Any station operated by a single person obtaining assistance, such as in keeping the log, monitoring other bands, tuning the transmitter, etc., is considered as a multi-operator station. Club stations may work in category C only. A separate log must be kept for each band and must contain the following data: date and time in GMT, stations worked, exchange sent and received, QSO points, and ITU zone multipliers (with first QSO in each zone only). The log must contain in its heading the category of the station (A, B, or C), name, callsign, address, band(s), etc. There is also a sum of contacts, QSO points, and multipliers and the total score for the participating station. Each log must be accompanied by a declaration that all rules and operating procedures were observed. A performance list of participants will be created for each country by the contest committee. A certificate will be awarded to the top-scoring operators in each country and each category. The "100 OK" award may be issued to the stations working 100 OK stations, and the "S6S" award may be issued to a station for contacts with all continents. Both awards will be issued upon written application in the log and no QSL cards are required. Logs must be sent to: the Central Radio Club, Prague 1, Czechoslovakia, postmarked no later than December 31st.

27TH ANNUAL BREEZE SHOOTER TEN-METER GROUND WAVE CONTEST

Starts: 2100 EST November 24
Ends: 0100 EST November 25

Sponsored by the Breeze Shooters, Inc., of Pittsburgh PA, this contest will feature separate categories for Novice/Technician, QRP, mobile entries, and fixed stations. For log sheets and rules, send an SASE to: George Proudfoot K3GP, 3472 Ivy Hill Lane, Finleyville PA 15332.

Awards

from page 22

years, the net has become a popular meeting place for 160-meter hams. The golden frequency was and still is 1818 kHz, and you'll find the net originating from the eastern shores of the United States each and every Wednesday evening at 2100 Eastern Time.

Keep in mind, should you wish to join the net, good conditions are more prevalent in the winter than in the summer months. This is important to mention due to the fact that many have listened on the frequency before and have copied nothing more than a high noise level in their respective areas. As will be noted by all of us at one time or another on 160, some nights are better than others.

Naturally, the net recognized the popularity of an awards program and now offers a very handsome certificate to those applicants meeting the requirements outlined below.

THE TOP BAND SSB NET AWARD

The Top Band SSB Net Award program was started in February, 1977, and is dedicated to those operators who check into the net either on three consecutive nights in which the net meets or on five non-consecutive nights in which the net meets. You should mail a copy of your log entries showing check-ins to the net registrar, Vic Misek W1WCR, 142 Wason Road, Hudson NH 03051, and be sure to enclose the award fee of $1.00 to cover the cost of printing, postage, and handling. Do not send an SASE since the award fee covers this cost.

Should any of our readers have 160-meter capabilities, why not join the fun? Should antennas be your obstacle, why not contact Vic and the group as there are several surprising antenna designs which are compact and cost under $5.00 to put you on the air with a respectable signal! And, of course, don't forget that in January, for the first time ever, *73 Magazine* will be sponsoring the 160-meter Phone Contest. More on this next month.

Traveling abroad, I wish to share with you information about a very respectable award being sponsored by the International Telecommunications Union (ITU) and the International Amateur Radio Club.

DIPLOME DES 100

This award is given by the ITU to radio amateurs and shortwave listeners everywhere in recognition of their achievement in communicating with, or logging the reception of, amateur radio stations in the territory of 100 or more member administrations of the ITU. Any licensed radio amateur or shortwave listener is eligible for this award. It is given to the individual, and the qualifying con-

tacts may be made over any period of time subsequent to the dates shown in the ITU official countries list available from the awards manager.

Applications shall be made by letter and shall include a list of stations claimed in alphabetical order, showing claimed dates. No special form is required for this purpose. Only frequencies, modes, and prefixes approved by the Radio Regulations of the ITU may be used. To qualify, 100 or more contacts must be made.

QSL cards or proper log entries will be considered proof of contact to back up an award application. Attached to the application should be a statement from two licensed amateurs or an ITU administration representative to the effect that all claimed contacts have been verified. No other proof is required. Do not send QSL cards! Do not send logs!

There will be no endorsements for special conditions. Stickers will be given for each ten (10) additional contacts.

The administration of this award has been delegated to the International Amateur Radio Club, 4U1ITU, PO Box 6, 1211 Geneva 20, Switzerland. The IARC has named Mr. L.M. Rundlett K4ZA as awards manager. All applications should be accompanied by 10 IRCs or US $2.00 for the award, and one IRC or a US self-addressed, stamped envelope for each sticker. Mail all applications to L.M. Rundlett K4ZA, Route 3, Box 447, Lake Placid FL 33852.

I received a very complete package of information from the Central Radio Club in Moscow and take pleasure in featuring their award program in more detail. It is unfortunate they did not send samples of their certificates, as I'm sure they are unique diplomas to possess.

R-100-O AWARD

This award (as is the case for all awards listed below) is issued to all licensed radio amateurs and shortwave listeners throughout the world who can meet the requirements. For the R-100-O, radio amateur applicants must carry out two-way contacts with, and shortwave listeners must log reception reports of, radio stations in 100 oblasts (provinces) of the Soviet Union.

There are three categories of R-100-O awards. The First Class is for two-way contacts on the 3.5-MHz band only, the Second Class is for two-way contacts on the 7-MHz band only, and the Third Class is for two-way contacts on any amateur band. All contacts must be made on phone or CW only. Endorsements will be given for each mode of operation, but cross-mode or mixed-mode contacts are not allowed. All reports exchanged between stations must be RST 337 or RS 33 as a minimum. All contacts or observations must be made on or after January 1, 1957, to be valid.

Applications must include a list of contacts or observations with date, calls, mode, and frequency shown in order of callsign prefix. QSL cards must be submitted along with the award fee of one ruble or 14 IRCs to cover the cost of the award and safe handling of your QSL cards back to you. One should allow three to six months for the processing of any of the awards I am describing. Send all applications and inquiries related to this or any of the following awards to The Central Radio Club USSR, Postbox 88, Moscow, USSR.

W-100-U AWARD

The W-100-U Award (worked 100 radio stations in the USSR) was established in 1959 on the occasion of the 100th anniversary of the birth of A.S. Popov, the great Russian scientist claimed to be the inventor of radio. For this award, amateurs must carry out two-way contacts on one or more amateur bands with 100 different amateur stations of the Soviet Union, including 5 radio stations of the 9th region (Minskaya). All contacts must be on either phone or CW, and applications must state which mode is to be credited for the award. Cross-mode or mixed-mode contacts do not count. All contacts must have been made January 1, 1959, or after and all signal reports exchanged must be at least RS 33 or RST 337 to be claimed. As with the R-100-O award, the applicant must prepare a list of contacts claimed and give the calls, date, frequencies, and type of emissions used to achieve the contacts. The cost of the award is 1 ruble or 14 IRCs, to be sent with your application, and QSL cards are required. The award fee is used to provide for the safe return of your confirmation cards.

R-6-K AWARD

The worked-all-six-continents award is offered by the Central Radio Club to amateurs and to shortwave listeners who can carry out 12 two-way contacts or observations on SSB, CW, and phone with radio amateurs as follows: one contact each in Europe, South America, Africa, Asia, North America, and Oceania, plus 3 contacts each in the European USSR (UA1, UN1, UW1, UA2, UC2, UP2, UQ2, UR2, UA3, UW3, UV3, UA4, UW4, UB5, UO5, UT5, UY5, UA6, or UW6) and the Asiatic USSR (UD6, UG6, UF6, UL7, UI8, UJ8, UH8, UM8, UA9, UW9, UV9, UAØ, or UWØ). The award has three categories: First Class is for two-way contacts on 3.5 MHz only, Second Class is for two-way contacts on 7 MHz only, and Third Class is for two-way contacts on any amateur band. As with all awards of the Central Radio Club, confirmation cards must be sent with your application. To qualify, all contacts must have been made May 7, 1962, or after. The award fee is 1 ruble or 14 IRCs—the same as it is for each of the awards of the Central Radio Club.

R-10-R AWARD

The R-10-R Award (worked 10 radio amateur regions in the USSR) is available to those who carry out, on one or more amateur bands, two-way contacts with 10 radio amateur regions in the USSR. These regions may also be termed call districts; in any case, numbers one (1) throughout zero (Ø) must be worked. All contacts must be made on either phone or CW. Mixed-mode or cross-mode contacts will not count. All contacts must be made after July 1, 1958, and signal reports must be a minimum of RST 337 or RS 33. The submission of applications and the cost of the award is the same as noted with the other awards in the Central Radio Club portfolio.

R-15-R AWARD

The R-15-R Award (worked with radio stations in 15 USSR Republics) is offered to those who work at least 15 of the 18 USSR Republics within a period of 24 hours. They are: European Russian SFSR, Franz Josef Land, Kaliningradsk, Asiatic Russian SFSR, Ukraine, White Russian SFSR, Azerbaijan, Georgia, Armenia, Turkoman, Uzbek, Tadzhik, Kazakh, Kirghiz, Moldavia, Lithuania, Latvia, and Estonia.

All contacts for the R-15-R Award must be made on CW or phone on or after July 1, 1958. Applicant must submit a list of claimed contacts giving date, emission, and frequency for each contact and must provide a QSL card for each contact claimed. Cost and mailing directions are the same as for the other Central Radio Club awards.

R-150-S AWARD

Probably the most sought-after award in the program offered by the Central Radio Club is the R-150-S Award. Amateurs and shortwave listeners throughout the world are eligible to compete for this award and must complete the following operating requirements to qualify.

The R-150-S Award requires the applicant to work at least 150 countries of the world and 15 Republics of the USSR from a special USSR DX Countries Listing.

There are no band restrictions, but contacts must be made on either phone or CW. All contacts must be made on or after June 1, 1956. Signal reports exchanged must be a minimum of RST 337 or RS 33.

Submission of applications and cost of the award is the same as noted for the other Central Radio Club awards.

Be sure to tell your friends to obtain a copy of *73 Magazine* next month, as we will surprise you with two more awards to add to our already famous *73 Magazine* Awards Program. Until then, continue to climb the ladder of recognition.

Ham Help

I am attempting, as part of full-time retirement, to combine family hobbies, the main ones being amateur radio and camping. I would like to hear from all amateurs who combine any form of RVing with amateur radio (QSLs, please).

Also, I am interested in obtaining information that could be used as a basis for future magazine articles and a possible book on the subject. I'm interested in pictures of stations inside RVs, information on antennas, etc. Do not worry about details, just the basics. If I need to, I will get back to you for more details. Credit for original ideas will be recorded and published when used.

Ward B. Baker K7YUC
PO Box 553
Prescott AZ 86302

I would appreciate hearing from anyone who has converted a Realistic TRC-52 23-channel CB rig to 10 meters.

John P. McCormick WB3IQW
110 Hilltop Drive
Severna Park MD 21146

Many thanks to all of you who mailed complete instructions on the Mosley TA-33 Jr. beam (Ham Help, July, '79, p. 180). I was amazed at the response.

Now I would like a circuit diagram of a Harvey Wells Bandmaster transmitter. I'm trying to rebuild an old unit, as it was the first commercial unit I used many years ago. Will pay for copy or I'll reproduce and return diagram.

Corrections

There has been considerable feedback on my article ("Hit The Panic Button!") in the August, 1979, issue. Most of the comments took issue with the statement that the reset switch "needn't be especially reliable" and pointed out further that the reset switch would carry the entire shack load, if any, until the contactor had time to close. These are excellent points.

Many of the comments suggested using a multi-pole contactor, with one set carrying the entire shack load, the other only the coil current; in this case the reset switch need handle only the coil current and can be light-duty. While multi-pole contactors with high current ratings are prohibitive in cost, heavy-duty relays can be had with a set of light-duty "auxiliary contacts," which would do the job just fine. The revised circuit is enclosed.

One suggestion proposed an enhancement including a number of reset switches in parallel with each other. This probably is not a good idea from the standpoint of safety. While the switches may be 99.99% reliable, paralleling a number of them increases the chance of one failing in the closed position defeating the system.

By the way, the contactor should be rated to *break* a current of at least three times the current limit of the shack circuit breaker. If you have a 30-Amp breaker feeding the shack, the contactor should be able to break a 90-Amp load. This is independent of the current *carrying* rating which, in this case, could safely be specified as 30 Amps. The reason for this is that the peak current differs from the rms current (just as peak voltage differs from rms voltage) and you have to design for worst case—and then add a safety margin.

One comment raised an excellent question: How do you know when the reset switch is open so the kill switch will work when you need it? In my case, I use a key-lock switch for the reset function. When I reset the system, I know the shack is alive because the clock starts running again. When I turn the switch back to remove the key, I can *feel* the switch operation. If the contacts were welded shut or somehow broke loose from the actuator, the switch wouldn't have the same "snappy" feel.

Another comment proposed using the kill switch as a "main power" switch, to make sure everything was shut off at the end of operation. This is probably not a good idea, for a number of reasons. First, you probably don't want to kill *everything* (the clocks, for instance) routinely. Second, shutting down a lot of equipment drawing a heavy load can, over a period of time, damage the contactor contacts and they may get sticky and not open when you really need them to open. A better solution, I think, is to use a separate "main power" switch, as I do, and as is shown in the circuit.

Interestingly, if you use a separate main power switch, you don't need the auxiliary contacts on the relay. Before resetting, turn the main power switch off. Then the only load on the reset line is the contactor coil (and perhaps a clock or pilot light). Once reset, turn the main switch on.

All of the comments are greatly appreciated. I would especially like to thank K8KK, WB2OVQ, and WD6FGX, along with others who omitted calls or from whom I haven't heard as of this writing.

2,670 kHz (U.S.C.G.)
2,738 kHz

*Revised Table 3, "Marine-Band Activity." HF ship-ship (plus limited coast) simplex channels. *Carrier frequencies are listed; listen on USB. The above 2-MHz frequencies are not, strictly speaking, in the same category, but are often used for similar purposes.*

I am enclosing a corrected Table 3 for my article "Marine-Band Activity," which appeared in the July issue on page 155. It lists new frequencies for ship-to-ship simplex operation. A change in assignments by the FCC occurred shortly after the article was written, and I missed this table in my proofreading. The remainder of the info is correct. Also, KQM in Hawaii has closed down, and station UIS is actually VIS.

Karl Schulte WA2KBZ
Hoffman Estates IL

Please note the following correction to my article "Add-On Keyboard for Your Keyer," which appeared in the August, 1979, issue. Fig. 2 contains a wiring error. As shown in the accompanying schematic, the following changes should make the Letter-Space oscillator work:

1. Pins 3, 9, and 13 of U3 should be connected together. Pin 3 should not be connected to the cathode of CR2.
2. Pins 6 and 1 of U3 should be connected to the cathode of CR2.

Edward J. Faber K4BZD
Columbia SC

This letter is in reference to my article "A Poor Man's CW Memory" in the June, 1979, issue of *73*. A number of people have written asking for ways to expand the memory. We now have a schematic available for a 4K version (twice the memory capacity) for 50¢.

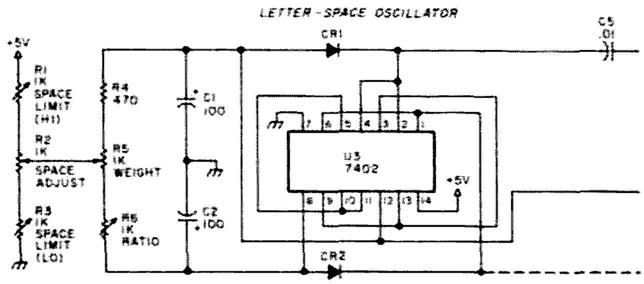
Eric Unruh WB0RYN
Rt. 2, Box 56A
Newton KS 67114

In my article "70-Watt Shoes for the IC-502," which appears on page 128 of the September issue, there is a minor mistake in the schematic diagram. The connection of the bias pot to relay RLY 1 should be reversed so that during standby periods the bottom of the bias pot is lifted above ground as described in the text. I hope this problem has not caused any inconvenience for readers constructing this project.

George Hovorka WA1PDY
Milton MA

There is an error in our article on constructing the E-Z Loader for the TRS-80 in the September, 1979, issue of *73* (pages 96 to 99). The circuit will work as shown as long as the optional LED driver is *not* used. If you wish to incorporate the LED minimum level indicator, the pick-off point for R12 should be the emitter of Q2, *not* the base of Q2 as shown in the article.

Additionally, a transformer for use as T1 is available from Radio Shack (part no. 273-1380), but only ½ of the 1k winding should be used. A note of caution: Several reports of reverse-



Revised Fig. 2, "Add-On Keyboard for Your Keyer."

biased Radio Shack 2N2222 transistors have been received. In these devices, the emitter and collector leads are opposite of normal, and even opposite of what is shown on the back of the bubble package!

If you are having problems with the circuit, drop us a note describing the symptoms along with an SASE and we will be glad to offer any help that we can.

In the September issue of *73*, on page 116, my article "The Amazing Audio Elixir" was published. Unfortunately, the TL081 called out does not seem to be available anymore. Builders should use the RCA CA3140E in its place. If one end of resistor R4 is lifted and a 1-uF capacitor is placed in series with it (with the positive end of the capacitor pointing away from pin 2 of the IC), a common 741-type op amp may be used.

A reader has correctly pointed out that there is an error in the article. The wire running from the gate of FET Q1 to the junction of C4 and CR2 *does not tie* to the junction of R2, R1, R4, and R5. If it were connected as shown, the circuit would not work, since the gate of the FET would be shorted to the source.

The article stated that the unit would drive even a small speaker. This was misleading, as the loaded down amplifier would work poorly, but you would hear something and it would not hurt the circuit. If a person wants to drive a speaker, he should use the Audio Elixir in front of another amplifier which can drive a speaker properly.

The demand for the PC boards was beyond expectation and my entire supply was used up within the first few days of the magazine mailing. I have ordered more PC boards from my supplier and hope I will have them before this letter is printed. If anyone is trying to deal with me and wonders why I am so slow, hang in there—I am buried in a mountain of mail.

One final note: If anyone is having trouble getting the CA3140E and the MPF111, I will supply them with the PC board if an extra $1.50 is enclosed.

New Products

from page 36

my version 1.1 of the M80 includes sections on operation and theory so that the great versatility of the system can be exploited. Ron Lodewyck N6EE, the president of Macrotronics and the system copyright holder, deserves much credit for the product. Directions for setup are clear, and the system has functioned well in the few months I've had it on the air. (I understand that version 1.2 will be available soon. This has some improvements in the machine-language timing routines.)

When the system is in operation, the user loads the machine and BASIC programs and can then select either Morse or RTTY operation. Several special functions can be selected in each mode so that the user has control of what will be keyed in transmit, speeds, etc. The unit transmits flawless CW and RTTY. Reception of strong TTY signals is possible with the onboard loop, but anyone really interested in RTTY will want to use an external demodulator. Reception of CW is perfect if one is copying W1AW or a station sending with a keyboard. Someone with a good fist will produce readable though not perfect copy, and many fists cannot be copied well. (Version 1.2 is supposed to help with this problem.)

I am going to describe a number of operating hints which may improve the enjoyment or versatility of the system. If you study the BASIC program, you can see how the program initializes various things such as keying polarity and speed. You can then modify a few statements to change the initialization. For example, the machine is set to key the "negative" transistor. The program permits the operator to change this to "positive" transistor and relay keying, but since I use the relay most of the time, I wanted it to initialize that way. The following statement changes the initialization routine to "positive" and relay keying: POKE 31346,4:POKE 31353,4:POKE 31364,3.

I use the system with the MLK-1 optoisolator instead of the relay and I have found that the loop is often latched up open at start-up. This presents no problem if a character is sent, since the first character will leave the loop closed, but if you don't notice the latch up and switch to RTTY receive, you can never get back to send. To help this I included the following: 6 X = INP(4).

Now when the program is run, the loop circuit is closed automatically. Furthermore, since my TRS-80 has a ROM error in the RESTORE routine, I include POKE 16553,255 in statement 6. That POKE fixes up the RESTORE routine and lets the M80 program run with no problems.

The program includes a routine which permits sending a CW ID while in the RTTY mode. The routine then forces the program to RTTY receive. That is fine at the end of a transmission, but when you send the ID at the beginning of a transmission, the system goes to receive and you then have to put it back to transmit to send in RTTY. To get around this, I added a routine that sends the CW ID but then keeps the system in transmit mode. I use the * key to enter this routine. The program steps are as follows: 13851 If B$ = "*" then 17050.

Statements 17050-17053 are then copies of program statements 17000 through 17010 except that instead of ending with GOTO20000, I end with GOTO10000 and the system stays in transmit. If you find that the loop latches open during this transition, just add X = INP(4) after X = USR(X) and the loop will get closed again.

I have found that these few modifications custom-tailor the system to my operation, but probably you will find some other minor changes that you would prefer. I also am using the system to drive my old Model 15 as a hard-copy output from the computer. The manual provides the necessary steps for doing that. Since a number of POKEs are required, I wrote these POKEs as a short program which is on tape just to save myself the typing each time I use the system. The following short program will let you use the system to get a hard copy of anything which is on the screen:

```
2  CLEAR 800
10 C$ = "":FOR I = 15360 to
   15614:C$ = C$ + CHR$
   (PEEK(I)):NEXT
20 POKE 30208, 1:POKE 30209,
   LEN(C$):POKE 30211,PEEK
   (VARPTR(C$) + 2): POKE
   30210,PEEK(VARPTR(C$)
   + 1)
30 MS = INT(30214/256):POKE
   16527,MS:POKE 16526,
   30214 - MS*256:X = USR (X)
   :LPRINT:GOTO10
```

To use this little program, you do the following. Enter the M80 machine-language program according to the instructions. Do the POKEs required for line-printing according to instructions. CLOAD this program. The statement numbers in this program must all be *smaller* than those in the program you are actually planning to use. Follow the method outlined by Roger Pape (*Kilobaud Microcomputing*, July, 1979, page 39) to permit saving this program while CLOADing another. When you get some material you want to save on the screen, you break out of the program which is running and type RUN 2. This program will run and will line-print the first three lines of the screen. It will pause at that point. If you want further line output, just hit CLEAR and three more lines will be printed. You then can break out of this program and begin your original program again.

Obviously, this little program could be incorporated as a routine in any other program to avoid the problem of loading two BASIC programs at the same time. These few lines create a string variable called C$ which consists of the characters on the first 3 lines of the screen (locations 15360 through 15614). This variable is then treated by the machine-language program as a "message" to be sent by TTY. The CLEAR command returns to the BASIC program.

These are just a few of the ideas I've had for the M80 system. As the originator says, the possibilities are virtually limitless since the board permits easy access to the computer. As you use the system, you will certainly come up with many other ideas.

THE RADIO SHACK® QUICK PRINTER II

Last year around Christmas, I convinced my wife that I should get a TRS-80 microcomputer. I justified it on the basis of my part-time business, which is statistical consulting. In reality, I use a much larger university computer system and didn't think a microcomputer would be of much help. Well, sure enough, the kids loved the games (even the wife enjoyed blackjack) and I learned a little about BASIC language, but not much statistical work was done. It wasn't long, however, before I expanded the system to 16K RAM and Level II BASIC and slowly but surely began doing more and more of my consulting work on the TRS-80.

One of the more frustrating aspects of getting into microcomputing is the growing desire

```

Fig. 1. Quick Printer II character set.

for more and more hardware. I could just visualize an expansion interface with 32K additional RAM and maybe a couple of disks. More important, I was really drooling over the possibility of some sort of hard copy. At the time, Radio Shack's cheapest printer was "only" $500, but that required the expansion interface (another 300 bucks). Now, for that kind of money my wife would probably divorce me, so my longings remained longings.

When troubleshooting (I guess the proper word is debugging) programs on the TRS-80, you use paper and pencil a lot if you get beyond 16 lines (the display capacity of the CRT). Since I was developing statistical programs of 100 or more lines with several hundred data entries, I was going nuts. Then Radio Shack came out with their Quick Printer II, a small and inexpensive ($219) hard-copy device measuring 3-5/16" × 6-3/4" × 9-1/4" (8.4 cm × 17.2 cm × 23.5 cm). I quickly ordered one and then waited close to a month for delivery.

The Quick Printer II uses aluminized paper 2-3/8" wide, similar to (but narrower than) the paper used in the larger Quick Printer. Some people say they don't like the black letters (5 by 7 dot matrix) on silver paper, but either they have a lot more money than I do or they enjoy looking at the CRT scroll through their lovely long programs. No expansion interface is required and the unit can be plugged directly into the TRS-80 bus on the back. If you happen to own the expansion interface, you also can plug into it using an optional ribbon cable. A third option is a serial (RS-232C) input at 600 baud. I suspect that this last option would enable owners of other systems to use the Quick Printer II.

Printing speed is 120 lines per minute at 64 characters per second. Pretty fast stuff, this printer. It isn't as quiet as the CRT, but it sure beats the old Model 15. (I use it a lot at night.) The characters available are a modified subset of ASCII-96 with uppercase *and lowercase*. (See Fig. 1.) Yep, lowercase! Lowercase is supported by the TRS-80 although, unmodified, it does not display lowercase on

```
HERE IS AN EXAMPLE OF TEXT OUT-
PUT IN REGULAR WIDTH
AND HERE IT IS
IN DOUBLE WIDTH
```

Fig. 2. Sample output showing double-width option.

the CRT—just on the printer.

Now for the bad part—at least some of you might think so—the characters per line: only 32 (or 16, software selectable; see Fig. 2). Now, admittedly, that doesn't seem like very many characters, but for my purposes I find it totally adequate. I'm not into word processing and I'm sure that 32 characters per line would be grossly short for that use. But for listing programs and data and providing hard copy of program results (such as statistical analyses), 32 characters per line is great. By the way, don't worry about exceeding 32 characters, as there is automatic wraparound (up to 263 characters). That is, if the output exceeds 32 characters, the unit automatically carriage-returns and line-feeds and prints out the rest on subsequent lines, but it certainly splits words in funny places!

The unit is well built, using an ABS plastic housing which matches the TRS-80. Besides the friction paper feed, there is only one moving part (the seven-dot print head). Expected print-head life is 30 million characters. Now that's a lot of output! Each roll of aluminized paper costs about two bucks and lasts and lasts and lasts. For one very large run, I bought four extra rolls and I'm still using paper that came with the printer.

If you carefully look at Fig. 2, you will see an example of variable vertical spacing. This is not a planned feature, nor is it desirable. However, it happens very rarely and only after you

have aggressively torn off the previous printout. The paper is a bit sensitive to oil and dirt, but once printed on seems to be very resistant to handling. Sometimes I do get a fingerprint smudge or two on it, but then I just wash my hands and run it off again. The printout reproduces very well and readily takes pencil or ink.

Now, how about ham radio use (this *is* a ham publication, isn't it)? Well, so far, I do two things: I keep my log in memory (sometimes) and print paste-on mini QSLs to attach to picture post cards of New Mexico for those special contacts. (See Fig. 3.) I also modified an excellent program for both the logging and QSL functions written by Charles Zappala WA7VZR for the October, 1978, issue of *73*.

All in all, I'm quite satisfied with my new printer. So if you need hard copy and operate on a slender budget, consider the Quick Printer II. I don't think you'd be going wrong.

Radio Shack, 1300 One Tandy Center, Fort Worth TX 76102; (817)-390-3272.

IC-551 50-MHZ FIXED STATION TRANSCEIVER

This microcomputer-controlled 50-54-MHz (SSB-AM-CW) fixed station transceiver uses a built-in microprocessor for frequency control and scanning. The 551 also uses the new style digital readout in green phosphorescent digits similar to the IC-RM2 controller. The no-backlash, no-delay dual vfo, light chopper system similar to the IC-701 and IC-211 is included as a standard feature. The handsome styling and small size of the unit provide function with flair to please the eye while matching the other Icom fixed station units.

Three memories are available for programming and beacon watching. Using the SSB squelch and scan mode, three beacon frequencies may be scanned and the 551 set to stop on the first one heard, thus alerting the user to the presence of conditions producing DX excitement. When not scanning, the three memories and two vfo provide five different frequencies for use by the 551.

The dual vfo system provided by the microprocessor allows split-frequency operation for contest and DX work as well as completely variable offset operation for six-meter FM (optional unit EX106 required for FM operation). The 551 uses the now-famous 100-Hz-per-step digital tuning system. Many thousands of satisfied users on SSB-CW and FM have proven the suitability of this system. For faster QSY, a touch of the button next to the main tuning results in 1 kHz steps. (In FM, tuning rates are 10 kHz per step normal, and 1 kHz per step with tuning speed button depressed.)

The 551 is an all-mode six-meter unit in a compact easy-to-use instrument. The large tuning knob (50 mm) provides the comfort and feel of a big unit while the small size provides the room you need at the console.

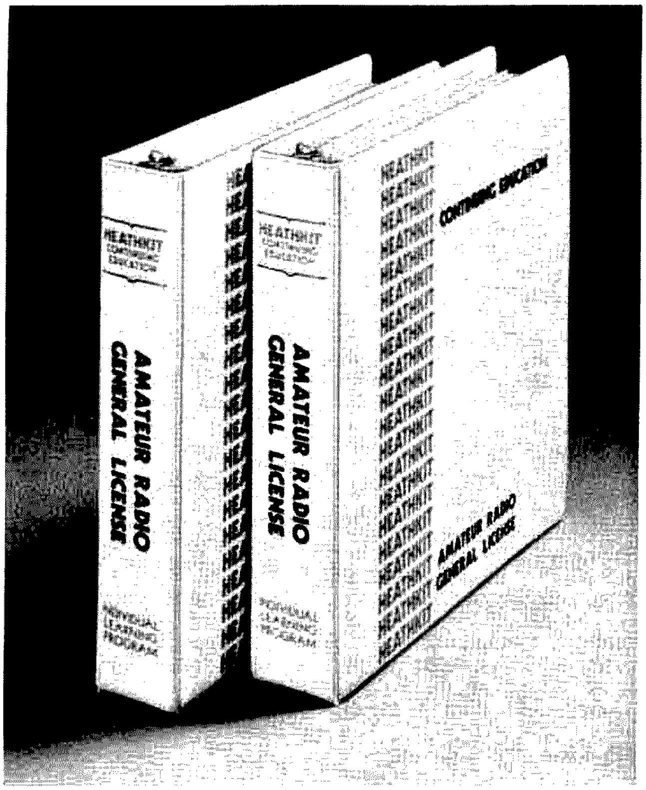
Icom, Suite 307, 3331 Towerwood Drive, Dallas TX 75234; (214)-620-2780.

Icom's IC-551 transceiver.

FCC GENERAL CLASS AMATEUR RADIO LICENSE SELF-INSTRUCTION PROGRAM NOW AVAILABLE FROM HEATH

A self-instruction program for passing the FCC Technician and General class amateur radio license exams has been introduced by Heath Company, world's largest manufacturer of electronics kits.

The program, divided into 15 units, covers the materials that FCC exams are based on. Unit exams check the student's progress while giving practice at exam-taking. Also included are cassette practice tapes said to prepare the individual to send and receive Morse code up to 15



Instruction program now available from Heath.

words per minute, two words per minute above the FCC General class requirement.

The program also includes a code-practice workbook, a world map of call areas, a booklet on solving radio and TV interference problems, a logbook, a copy of FCC amateur radio rules and regulations, FCC Form 610 required to apply for the exam, and a schedule of exam dates and locations.

The program carries a money-back guarantee should the purchaser fail the Technician or General class FCC exam. The program is described in the latest free Heathkit catalog. For a copy, write *Heath Company, Dept. 350-890, Benton Harbor MI 49022; (616)-982-3417.* Reader service number H5.

3½-DIGIT PORTABLE 0.1% DMM OFFERS LCD READOUT AND RF INTERFERENCE SHIELDING

A unique new portable DMM has just been announced by the B&K-Precision product group of Dynascan Corporation. The Model 2815 is a compact instrument that is protected and shielded against rf interference so that it retains its accuracy in rf fields. As a result, the 2815 can be used near two-way radios or broadcast transmitters up to 450 MHz. This new design features high resolution, excellent overload protection, and 0.1% dc accuracy.

The resolution of the 2815 permits its use in exacting R and D applications. For example, the 10-Ohm range offers 0.01-Ohm resolution for accurate resistance measurement of switch and point contacts, motor and coil winding, wire lengths, or any low-resistance circuit. Current resolution is 100 nA and the 100-mV scale permits voltage resolution to 100 uV.

A major feature of the 2815 is its protection against accidental overloads on all ranges. In the Ohms range, where this protection is needed most, the 2815 excels. Its design will resist damage from momentary overloads up to 1000 volts dc or ac peak. Continuous Ohms protection is +1000 V dc and −450 V dc or 350 V ac. The 10-Ohm range will momentarily sink currents of 3 Amps without damage. Current ranges are double-protected by both diodes and a fuse.

The large LCD readout of the 2815 is designed to be used in bright sunlight, making the unit ideal for field-service applications. An inexpensive 9-volt alkaline battery powers the 2815. Low-battery warning indication is automatic. Auto-zero and auto-polarity are also featured.

According to Gus Rose, Director of Engineering, "the B&K-Precision 2815 employs new LSI technology for accuracy and reliability. Our LSI integrated circuit is highly immune to stray rf fields, but for still more protection, we provide internal case shielding. We strongly believe that for dependability, a DMM should be able to perform accurately in rf fields."

The B&K Precision Model 2815.

The new B&K-Precision 2815 portable DMM is now available at local distributors. It includes test leads, built-in tilt stand, detailed operating manual, and spare fuses. A wide range of optional accessories is available. For additional information, contact your local distributor or *B&K-Precision, Dynascan Corporation, 6460 West Cortland Street, Chicago IL 60635; (312)-889-9087.* Reader service number B45.

OPTOELECTRONICS K-7000 FREQUENCY COUNTER KIT

It doesn't seem too many years ago that hams were clamoring for surplus BC-221s and LM frequency meters for frequency calibration in their shacks. To be sure, these venerable vfos did provide good stability and fair readout accuracy for the user—by consulting look-up charts. But the scene has changed dramatically. Digital technology has opened up no-nonsense measurement techniques. Visual displays feature bright readouts of frequencies directly—no interpolation required.

The term "frequency counter" refers to the fact that the actual periodic pulses of the source being measured are summed for a period of time (called the gate time), and the total number of pulses per time unit is displayed. Assuming the reference frequency of the time-base or "clock" is accurate, the frequency counter can't miss. It's about as absolute a measuring device as you can find.

The new K-7000 550-MHz frequency counter from Optoelectronics is an excellent example of this new technology. Featuring seven bright, large (.4") LED characters, actual frequency performance will typically reach 600-700 MHz! At this writing, the K-7000 is advertised as the cheapest 550-MHz counter kit ever available—less than fifteen cents per megahertz!

This neat little package costs less than $80 in kit form. The K-7000 is compactly contained in a rugged metal cabinet, not in a flimsy plastic shell as are many competitive units. It measures down to 10 Hz, making audio applications a natural. With a top end in ex-

cess of 550 MHz, measurements of rf through UHF are a snap.

Input impedance is 1 megohm, shunted by 20 pF (up to 55 MHz) or 50 Ohms (up to 550 MHz). Gating times are switch-selectable between .1 and 1 second. An automatic decimal point is included. Resolution of the display is 10 Hz at 55 MHz or 100 Hz at 550 MHz. Sensitivity is better than 10 millivolts up to 55 MHz, increasing to 50 millivolts (nominal) at UHF. It is typically 20 mV at 2 meters.

A temperature-compensated quartz crystal timebase (TCXO) features first-order linear compensation, providing stability of better than ±1 part per million at room temperature. Aging of the oscillator is less than 2 ppm per year, making calibration unnecessary for long periods of time.

While many pieces of test equipment require sophisticated power supplies, the little K-7000 will accept anything between 7.5 and 15 volts ac or dc that can supply 250 milliamps! Internal rectification and regulation will take care of the rest. An optional ac power supply is available (#AC-70 for $4.95), as is a nicad battery pack/charger circuit (#Ni-CAD-70K for $15.00). A telescoping whip antenna with a right-angle BNC connector is available for $9.95. A wide variety of additional accessories is available to extend the flexibilities of this versatile counter even further. The K-7000 measures only 1-3/4" H × 4-1/4" W × 5-1/4" D and weighs less than a pound.

Kit assembly involves 40 short steps, including checkout procedures. Directions are concise and clear.

The manual which accompanies the K-7000 is well-written and liberally illustrated. It contains an excellent theory section to acquaint the newcomer with operational theory as well as practical applications of the instrument.

An endless variety of applications for the frequency counter appears around the ham shack. Sitting adjacent to the rig, whip extended, the counter will display your actual transmitted carrier frequency (assuming some stray rf leakage during transmit). Whether or not you have digital readout already or think you know your band edges, the counter provides backup protection against pink tickets!

Loosely coupled to the oscillator of a receiver, the unit will display your receive frequency (plus or minus the intermediate frequency used in conversion). A simple outboard mixer circuit will enable the user to read received frequencies directly without having to consider i-f offset.

Hooked to the output of an rf signal generator, even the most inexpensive generator suddenly becomes an accurate piece of test equipment.

Various mixer products in receivers and transmitters can be checked for proper alignment, as well. And, by probing various points throughout the circuitry, the counter can be used to determine which stages are operational. For example, if a receiver appears to be dead from a received signal standpoint, the oscillator and mixer stages can be sampled for frequency output.

And finally (and certainly more esoteric), for the frustrated spies among our readers who always wanted to know the output frequency of a transmitter at a government office: Watch the display for a few minutes in the vicinity of the antenna in question. The closer the better. With reasonably short distance between the little unit and the transmitting antenna, a sudden stable readout is a direct giveaway of the transmitted signal frequency!

For more serious applications of this nature, Optoelectronics also offers a model AP-8015 broadband amplifier capable of providing a nominal 25 dB gain from 10-1000 MHz or more. Used in conjunction with the K-7000, discrete transmitted frequencies may be measured from considerable distances.

We would rate the K-7000 an outstanding value for hams as well as service technicians.

The K-7000 frequency counter kit is $79.95 from *Optoelectronics, 5821 N.E. 14th Avenue, Fort Lauderdale FL 33334.* Reader service number O3.

Ham Help

How long can amateur radio survive in Arizona or anywhere else if a "closed-shop" atmosphere prevails? How can a newcomer enter this select group unless a friendly hand is extended? Where are the new hams going to come from if there is no Novice program functioning?

Since moving to Tucson 5 months ago, I have been unable to make contact with any radio club, and I have seen no evidence of any effort to teach or introduce would-be hams to our hobby. This comes as a real shock to me, and I can only hope that my initial impressions are wrong.

As a federal employee, I have spent 20 of my 32 years overseas, where the spirit of helpfulness and friendship was dominant among my fellow MARS members and the Canadian and British hams whom I came to know. We worked together in maintaining and repairing our rigs, held antenna-raising parties, operated various emergency nets, and studied and later taught code and theory classes that were free and open to all interested parties. I am proud of the friends I have known, and I count these years as the most enjoyable years of my life.

If my admittedly bleak impressions of Arizona are correct, and if they are generally applicable to the rest of our country, then amateur radio is unquestionably doomed! If the amateur spirit dies, then the question of survival in the face of possible losses in spectrum becomes academic. Hopefully, this situation is reversible.

I am now retired, but I am not dead yet. I am available to teach code or theory or to help in any way that I can to ensure that amateur radio is alive and well in the state of Arizona.

Thomas J. Gilliam W4NHX/7
4426 E. 22 St., Lot 93
Tucson AZ 85711

I have picked up a transmitter/receiver system and don't have any manuals for it. I have asked many people, but nobody has ever seen it before! The system consists of four units, and the only numbers on them are RR-6, RP-6, RT-6, and RA-6.

The receiver, RR-6, covers two bands: 3-6.5 and 6.5-15 MHz. It is a superhet with an rf amp. It is all tubes, has a bfo, crystal calibrate, and can use crystal control. Size is 6½" x 5" x 2½".

The transmitter, RT-6, covers two bands: 3-7 and 7-16.5 MHz. It is crystal controlled only with output for a longwire antenna. Tubes are a 2E26 final and a 6AG5 osc.-driver. It is CW only, with built-in key. Size is 6½" x 5" x 2".

The power supply, RP-6, provides all voltage required for both receiver and transmitter with any one of the following inputs: 70-270 V ac, 40-400 Hz, a GN 58 hand generator (I don't have this), or a 6-volt storage battery. The RP-6 will also charge a 6-volt storage battery with an ac input. Size is 4" x 8" x 2". The RA-6 unit is a function box. Size is 4" x 8" x 2".

I would appreciate any help in identifying this gear.

John Oppenheimer WD5GNY
165 Woodruff St.
San Angelo TX 76903

I have been unable to locate a source for manuals for the following pieces of test equipment from the original manufacturers and hope someone out there can help. I will pay for a photo copy, or I'll copy and return. Write first to prevent duplication.

Technology Instruments Co., Inc., model 311-A rf Z bridge;
Eico signal generator, model 324, and ac VTVM and Audio Load, model 260;
Midland CB xcvr tester;
Bell & Howell Schools electro-lab design console.

Any help would be appreciated.

Robert Monaghan W5VC
PO Box 2182, SMU
Dallas TX 75275

I am in great need of a service manual, user's manual, schematic, or any other information for the Hammarlund HQ-129X receiver. Hammarlund is, unfortunately, out of business and this manual seems to be very hard to find. I will pay postage and duplicate promptly, or reimburse your copying cost. Thanks.

Fred Goldberg WA2BJZ
29 Clearview Road
East Brunswick NJ 08816

I would like to obtain a ham-band receiver (not necessarily working) for up to $25. Type and vintage are immaterial. I will pay by bank draft before shipping.

Daniel Bell ZL1AKV
Box 5676
Auckland NZ

We would like to swap QSL cards with anyone. We would also like to make contact and exchange information on radio communications.

George Szekely AK4458
PO Box 348

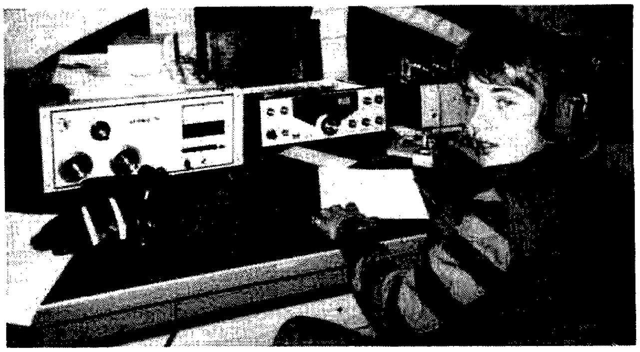
Faces, Places

Jonelle Lewis KB4RS of Franklin, Georgia, was the first female ever to graduate from the electronics study program at Troup County Area Vocational Technical School in LaGrange, Georgia. She was at the top of her class academically throughout the program and accomplished some remarkable things. She acquired her Radar Endorsed First Class Radio Telephone License and her Advanced amateur license within a period of two weeks. Each was acquired on the first attempt and in one sitting.

On June 7, 1979, Captain Thomas C. Watson, Jr., Commanding Officer of the aircraft carrier USS Independence (CV-62), presented awards to Norfolk area ham operators in recognition of their handling of phone patch traffic between the Indy's crew and their relatives and/or friends while the ship had been at sea. Ham operators aboard the Independence were also cited for their efforts. The awardees have been handling Indy's phone patches since she left the Portsmouth Naval Shipyard last September and will also handle the phone traffic while the ship is underway during its upcoming deployment. Pictured left to right: Marty Roberg N4BKL, Wayne Walker WD4MNP, Kevin Newberry WB2NGL, Gib Patterson WB6VIE, Jeff Parker WA1WXL, George "Ike" Ikonen WB4NEE, Bill Keller WA4FCK, Bill Ames WB4CUY, Ralph Chamberlain N4AXM, Jerry Oxenburg WA4RQU, Bob Edward WB4ZSE, and Wes Woessnen WB4ZSQ. (Official U.S. Navy photograph by Phan Webb)



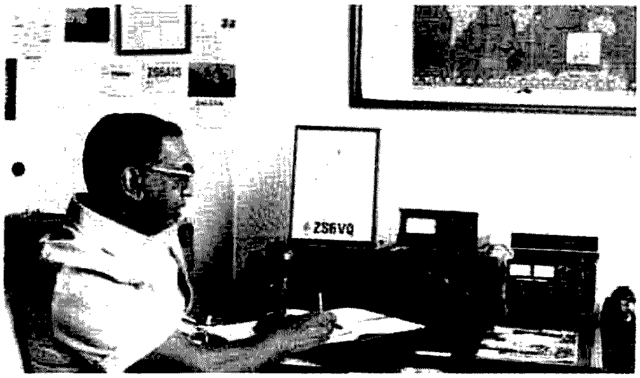
Contrary to what our October, 1978, article stated, Dick Torrey WB1EEM (age 13) of Rockland, Massachusetts, was KM1CC's youngest operator.

FIELD DAY, 1979, FOR THE SOUTH EAST AMATEUR RADIO CLUB (K8EMY) OF CLEVELAND, OHIO

Photos by Al Willinger WB8PMB

The Novice/Tech station of K8EMY. This station was run totally on dc using an auto battery charged by a small gas generator. At left is Ron Headley WD8QAZ and at right is Ron Wexler KA8CBQ. Also pictured is a minicomputer lent to the club by "Computerland." This Apple was used to log contacts and keep track of points. The antenna for the station was a mobile one located on WD8QAZ's Honda.

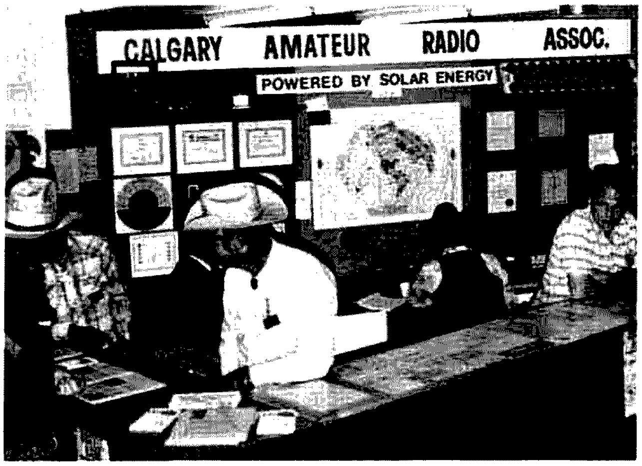
K8EMY's phone station. Left to right: Kevin Ritchey WB8YXU, Dave Hubbert WD8KIS, and Jon Taylor WB8TTP. This station ran off a gas-powered generator donated by Ohio Bell Telephone. The antenna for this station was a TA-33 Jr. on a monopole mounted alongside the pavilion at the city park in Shaker Heights that was the club location.



Goolam Karim ZS6VQ was the first Indian ham in South Africa to obtain an operating license. He is a doctor practicing in Bethal, an Eastern Transvaal town. To encourage improvement of their Morse code speed, new South African hams for the first 12 months are restricted to CW on the HF bands.

SOLAR-POWERED AMATEUR RADIO STATION AT THE CALGARY STAMPEDE

Photos by T. Mountjoy VE6MX



The Calgary Amateur Radio Association station VE6UN with some of its volunteers manning the booth. Approximately 75,000 people visited the booth and got a first-hand, first-class glimpse of an operating ham station. The station operated 13 hours a day and while in operation was the subject of two well-produced television documentaries.

The power supply and tribander up on the roof of the exhibition building housing the station. The solar panels shown provided enough power to keep the six 105-Amp batteries stored at the base of the panels always close to full charge.

Billy Hassler KA7DOV (age 7) recently became the youngest member of the Cheyenne, Wyoming, ham family which also includes Dad, Jim WB7TRO, Mat KA7CPD (age 14), and Jean KA7CWO (age 12). The Hasslers give much credit to instructor Bob Madden WA7YHK.

Promoting amateur radio on a 30-minute television program on KRIS-TV in Corpus Christi, Texas, were (from left) David Horton K5GT, Bob Douglas W5GEL, and Joe Cowen WA5TUM, with show host Judy Wenger of the Texas Coastal Bend Council of Governments. The program, "State of the Region," was aired at noon July 14 and again July 18 and traced the history of amateur radio, gave insight into the public service benefits of the hobby, and stressed the versatility of the hobby and its technical contributions to communicative art. A radio version of the program with Cowen and Wenger was broadcast over 10 commercial AM and FM South Texas radio stations. Horton is a board member of the Texas VHF-FM Society, Douglas is widely known in amateur radio circles due to his affiliation with Douglas Electronics, a Corpus Christi ham store and wholesale elelctronics parts network, and Cowen, secretary of the Beeville, Texas, Amateur Radio Club, is public information director of a college in the Texas Coastal Bend. (Photo by W5PIL)

Pictured in front of the Chicago Area Radioteletype Repeater System are (left to right) Ben Delaney WB9RTX, Neil Petlock K9WRL, and Howie Olson WA9KEK. The CARRS repeater went into service on July 9, 1979, and is the first teletype-only repeater in the Chicagoland area. This repeater is located in the new two-meter subband at 144.71 in/145.31 out.

W2NSD/1 NEVER SAY DIE

editorial by Wayne Green

WARC RESULTS

By the time this gets into print, the WARC results will probably be known—such are the delays of the magazine biz. This is being written considerably before the event in order to set the record straight.

One of the questions which came up during my recent visit to the Philadelphia Area Repeater Association meeting in Valley Forge was my opinion of what would happen at WARC. My answer has not changed in the last couple of years . . . I have no opinion on what will happen . . . there are just too many unknowns involved. I know that I would feel a lot more positive about it if I had seen any significant evidence that amateur groups were doing something in preparation to meet some of the problems which were evident.

In my editorials and talks, I have given the facts on events which have happened which I think are pertinent and which could influence the WARC results. I try hard to make amateurs understand that these are facts of history and not my opinions. It is a fact that amateur radio went into the ITU conference on satellite frequencies with allocations for over 100,000 MHz above 500 MHz and came out with zero . . . nothing. This is not opinion, and it is verifiable in the most revered of sources: *QST*. The ARRL people admitted that they had not done their homework and this was the reason for this catastrophic loss. I think I am not exaggerating when I categorize the loss of virtually the entire future of amateur radio by satellite as catastrophic. Below 500 MHz, we also lost 90% of the 450-MHz band and 100% of the 220-MHz band for satellite use.

The maritime ITU conference in 1972 resulted in another terrible loss of frequencies by white nations as the African and Asian countries banded together, ignoring all technical recommendations, to grab their "share" of the frequencies . . . no matter any intended use or not. This again is not opinion, it is a fact.

If the Third World countries get off this kick of getting everything they can at ITU meetings, we may come out okay, so when I'm asked for my predictions of what will happen, I can't be optimistic . . . nor can I say that I think we will lose 40m, etc. I do say this: If we do lose frequencies, we know where to place the blame for it . . . on those who had the responsibility to protect these frequencies and did so little in that line. Oh, they knew what had to be done, but they just didn't do it. They learned nothing from their debacle in 1971.

Should amateur radio come out with everything we have at present . . . plus a couple of extra bands, no one will cheer more loudly than I. And no one will be luckier than the League. I still won't be able to honestly give them one bit of credit because they have gambled with our future by not doing everything reasonably prudent to try to preserve it. Just hoping for a lucky break hardly constitutes providing the service we expect of them and pay them for.

AN ACCOUNTING

Once this is over, I think the members should flatly demand an accounting of the funds spent in Geneva. The last I heard, they had $140,000 in their wallet and were sending out more letters begging for money for the WARC "crew." Many angry members sent me copies of an August 31st letter . . . a bit late in the game for hat-passing, I'd say.

It may be almost time for League members to stop ignoring what is going on and start asking questions.

MONSTER GREEN

Rather than come up with figures to show that I was wrong in my questions about the ARRL living it up at the expense of the deluded members, they've chosen to attack me personally. "Green is anti-amateur radio," I hear. Or "Green is egotistically trying to torpedo ARRL participation at WARC 79."

I suggest that the facts be brought out. Either I am right about the $100,000 fund for protecting amateur radio or I am not. And all anyone has to do is read the yearly ARRL report. Whitewashed as it is, the fund is right in there for anyone to see. If I am wrong about the fund, then I think a lot of members are due an explanation of why the fund is listed (and has been for years) in the annual reports.

Let's suppose that eventually they will admit to the fund. How then can they justify the hat-passing for more cash? This strongly suggests that they intend to spend more than $100,000 at Geneva! How much can a couple of people spend in a few weeks? Sure, Geneva is expensive, but even at the finest hotel, which I am sure they have engaged, and at the most expensive restaurants, which I'll bet they are patronizing, it should be difficult to spend *that* much money in so short a time.

Say, I'm willing to bet $100 cash that not one of the ARRL members will be able to get a list of the monies which have been spent from that $100,000 fund since it was set up. It has been brought back to strength each year by the directors, and no report has *ever* been made that I have seen on where the money went which was spent. The first person to come up with a list of the expenditures, by whom, for what purpose, and when, gets my $100. Boy, am I safe on *that* bet. I *know* what some of the money was spent for and I *know* it will never be made public.

My apologies to ARRL insiders for stirring up skeletons in closets, but when the direc-

Microfilm Edition—University Microfilm, Ann Arbor MI 48106.

tors go out to clubs and start trying to smear me, as a cover-up for their crimes of omission and commission, then I speak up.

Me anti-amateur, huh? And pro what? Let's put it this way . . . I will say flatly that there is not one official of the ARRL at any level who can even come close to my background in amateur radio. For those new readers who might get taken in by a director, let me give just a brief resumé of some of my ham activities.

In the DX field, I've got well over 300 countries confirmed . . . have visited almost 90 countries and operated from over 40. I've been active on OSCAR and have some 30 countries worked through the satellite. On 10 GHz, I have the world's record for states worked: seven. I was one of the pioneers of RTTY and wrote several of the early books on the subject. I also was an early experimenter with slow scan and forget how many countries I've worked on that mode. I had one of the early repeaters and pioneered multiband repeating . . . with my first work on repeaters being in 1949, thirty years ago.

How about contests? If you look back, you'll find that I've won my section several times in the Sweepstakes, DX, VHF, and other contests. Love 'em. The rarest countries I've worked from? Probably Afghanistan as YA1NSD, Nepal as an op at 9N1MM, Tahiti with my FO8AS call, Fiji as VR2FD, and Jordan as JY8AA. I will have been on from Korea as HL9WG and from Hong Kong, with call as yet unknown, in October.

These days I'm active mostly on 20, 15, 10, 2, 1¼ meters, and 10 GHz. But then, I lead a fairly busy life and haven't time for everything. Anti-ham? How many ARRL HQ people have you heard on the air? I haven't heard 'em and I drive right through Hartford every now and then operating on two meters.

FCC BEING PUT DOWN

Not only hams are getting sick of the FCC. I see more and more newspaper clippings from readers about the FCC, none complimentary. Having attended more hearings at the FCC than I like, I can see why the outfit is constipated. Some of my petitions for rule changes have been in the works for ten years and are still hanging around waiting for action.

We might be able to put up with this glacial speed if the results were well considered and fair. They are anything but. Politics is the rule of the day, along with temporary expediency.

One of the major problems at the FCC is that it is being run by seven people, none of whom have the background needed to make decisions on the complex matters involved. This means that every problem has to be explained in tedious detail, written for the complete novice, and it also means that the writer of these details can sway legislation easily by biasing the position papers.

The FCC is trying to handle a wide range of regulations, each requiring a technical background which the commissioners do not have. The result is that some of the commissioners realize the futility of their jobs and just sit back, voting whichever way seems best, but not even trying to make sense of the situations. Some virtually sleep through the long boring hearings.

If the FCC is going to be able to make any intelligent decisions, they are going to have to find some way to get career people with the needed background into the job—not uninterested political appointees. No one can have all of the background needed, so some splitting up of the divisions is needed, with separate heads. The present system of endless oral hearings must be curbed in some way. It is just too much of a waste of time for too many people.

I think it was about a year or so ago that a reader (an old friend who used to work for me) wrote, suggesting that he start a movement to get me appointed to the FCC as a commissioner. I wrote back and said no way. I wouldn't last a week in that bureaucratic environment. I believe that the shortest distance between two points is a straight line, even if it bisects the White House and two other commissioners.

No rational body would have come up with the ten-meter linear ban, which doesn't make any sense. And now that CB sales have dwindled off to where there is virtually no problem with HFers or illegal CBers of any magnitude, I would expect the Commission to go right ahead with plans for dealer registration of ham equipment . . . the requirement of a ham license to buy, etc. The molasses speed of the FCC forces it to provide rules long after the need for them has gone away. Remember the repeater rules, if you will . . . totally unneeded when they arrived because amateurs had already solved the problems which had originally brought on the request for the rules years earlier.

Part of the trouble lies with hams. All too often I see petitions to the FCC intended to solve some temporary problem . . . and I know that years in the future this petition may well cause great mischief. And then we have hams who are afraid to go ahead and experiment with something. They want to make sure that it is all okay with the FCC before they go ahead. The result of that is that the bureaucrats at the FCC are not about to open themselves to any possibility for criticism, so they say no. If the damned ham would just go ahead, but shut up about it, the chances are good that nothing would happen and then we could point to a year or two of operation using the experimental system with success and, at that time, get it okayed. Bureaucrats say no . . . they have to if they want pensions.

If I could see examples of our government providing benefits to us, I might be less critical. I suppose the police system we have is better than none at all, but, at times, I am not sure of this. I see people quitting work because they can make almost as much on welfare and not have any responsibility. After a couple years of that, who will ever hire them? And so it goes . . . many books have been written about this mess we've gotten outselves into . . . and no one has even a hint as to how to get out of it.

About the only good thing you can say about our government is that, crummy as it is, we don't know of a better one anywhere.

WHICH ONES WORK?

Unless you are brand new to *73 Magazine*, it should come as no great surprise to you that I have a considerable interest in 10 GHz . . . and this even extends to the neighboring band of 10.5 GHz, where the police have set up a great little moneymaker by zapping motorists. This nets them well over $3 billion a year in cash for their municipalities, making it possible for a $1,500 radar unit to pay for itself in a weekend!

The *73 Magazine* mobile office and portable laboratory has four different radar detectors mounted across the top of the front window. This is not so much because the lumbering Dodge van is operated above 55 mph as it is to test the ability of these units to detect signals of importance and reject those of insignificance.

The four units currently in test in the van are the Bearfinder, the Fuzzbuster, the Super Snooper, and the Radio Shack Micronta unit. Up here in New Hampshire, we have no shortage of radar in the hands of police . . . In fact, virtually every state police car has one and many of the town cars sport them. A simple trip to Manchester, some 35 miles away, can often supply three or more tests of the detection devices.

One of the best we have tested recently has been the Radio Shack Micronta unit. It looks very much like the Super Snooper unit in the ads, but when ours arrived, we were surprised to find that though the shape was quite similar, the size was substantially smaller. The Micronta generally advises us of a lurking bear a second before the Fuzzbuster, which has come to be a good standard to use.

I'm partial to the Fuzzbuster for a couple of reasons . . . firstly, because it does always give the alert in time to check speed and slow down a hair, if needed. Secondly, this firm, Electrolert, has been by far the most active in fighting illegal laws put through to limit the use of these radio receivers.

As I've mentioned before, on most of the larger highways and turnpikes, the traffic tends to run from ten to fifteen miles per hour over the 55 limit, which means that the bears have a field day when they set up shop. The use of CB and an ear on channel 19 can save you a stiff fine, the hassle of coming back to some crummy place for a court hearing a week or two later, and an increase in your insurance premiums. It may also save your driving license.

I had a very good friend who used to go with me on sports car rallies. A cop. He said that his friends would give almost anything to get parkway duty, since this meant an added nontaxable income of several hundred dollars a day. The patrol cars kept track of commuters in expensive cars and stopped them about once a month for speeding. Unless the motorist was particularly dense, there would be a $50 bill neatly folded within the driving license. The police would look at the license and hand it back, less the $50.

The radar detectors are handy because it is all too easy to go along with the traffic and find yourself a few miles over the speed limit. You're not going fast enough to get there any sooner, but it is fast enough for

NBVM

Because of some late developments, we were unable to present in November the article on NBVM mentioned in "Never Say Die." Tim Daniel N8RK's report will be featured in our January, 1980, issue.

a ticket, court appearance, fine, and insurance increase. When the detector sounds off . . . which is a cacophony in the van, with four going at once . . . I have about one second to hit the brakes before the police radar units can read out my speed. Their radars have to read the incoming Doppler audio tone and change it to miles per hour. This takes a couple of seconds. If the target car is changing speed, the radar unit can't get a fix on it, so you always have time to slow down, if you are properly warned.

If it wasn't for the 55 mph speed limit, I doubt if I would even have the van. It burns gasoline ridiculously, averaging about 11 miles to the gallon. But it has a 36 gallon tank, so we have a range of nearly 400 miles with it. When someone else is driving, I can read manuscripts, answer letters, keep up with literature, and things like that . . . all without the constant interruption of the telephone.

For faster trips, we generally use the Mazda RX-7 . . . which we like very much. There are only three radar detectors on it normally . . . a Fox, a Whistler, and a Bearfinder. The Whistler sometimes sounds off when within twenty feet of a radar transmitter and on the more severe bumps . . . but that's all. The Fox and Bearfinder are about even. The RX-7 burns less than one gallon of gas for every 20 miles when driven at speed (80 mph), even with air-conditioning and automatic shift.

The Fox and the Micronta are pretty close when I plug a Fox into the van system for a comparison. It is difficult to see any real difference in sensitivity . . . both are very good.

Like many other gadgets, once you get used to the warnings from a radar detector, you feel worried without it. Since I'm often chatting away on two meters while I'm driving, generally keeping up with traffic unless I am in a hurry for an appointment, I don't keep my eye on the speed at all times. The warning buzz is appreciated and often saves me a brush with the government.

JAMMING—CAN ANYTHING BE DONE?

Who can fail to get angry when they hear amateurs trying to jam out an emergency net during an earthquake or hurricane? Sure enough, right in the middle of a recent extended period of critical traffic handling, there were some jammers making life miserable for everyone. I understand that the FCC was called and, using their sophisticated direction-finding equipment, quickly located the scoundrels.

Jamming is certainly nothing new in amateur radio and perhaps it is past time to bring it out in the open and stop pretending that it isn't happening. By discussing it, we may be able to better come to grips with the problem . . . and also come up with some plans for dealing with it.

Though there are obviously some common causes and common remedies which apply to jamming, we may be able to tackle the phenomenon better if we break it down into categories. We have the jamming of emergency nets, probably one of the worst types of jamming. Then there is the jamming of what we term service nets . . . such as the Eastcars, Midcars, and Westcars nets. We also have jamming of just plain nets. We have jamming of special modes such as RTTY and SSTV, a sort of specialized breed of jammer. And most of us are familiar with the kerchunker on repeaters . . . and we've even heard the bad-language fan lousing up repeaters.

In addition to those jammers, we have a whole host of jammers working in our DX bands . . . and I'm not speaking about commercial or military stations which are intruding. I'm talking about your sanctimonious DX chaser who slams his signal into a pileup, knowing full well that it is flatly against the law to intentionally interfere with another operator. In this case, jamming is not only condoned, it is a way of life, complete with high-powered amplifiers and giant antenna arrays, all set up with the sole purpose of being able to jam the hell out of several dozen other stations who are trying to reach a choice DX station. Choice, did I say? I've heard pileups on a YV or even a DL when there is nothing rarer to fight over.

WHY?

In some cases, there is obviously a screw loose in a ham's head. They don't give tests of sanity when they hand out ham tickets, so we have our share (and more) of loonies. I've heard more than one ham wife claim that all hams are nuts and, after forty years of this and knowing several thousand hams personally, I'm in no shape to argue the point. I know there are hordes of hams who would sign commitment papers for me if they were passed around.

But let's get down to the nitty-gritty . . . *why* this happens. I'm immediately reminded of a time when I was operating from Curacao (PJ3) and I checked the band carefully for a relatively empty spot . . . found one . . . asked twice if anyone was using it . . . called CQ and got into a contact. About five minutes into the QSO, a woman from Florida broke in on the channel and demanded that I get off the frequency immediately, saying that I had one hell of a nerve operating there, since this was the YL International Phone Net channel. Without giving me a chance to say anything, she proceeded to make a ten-minute call for net members to gather . . . and got some. If ever I wanted to jam a net, that was it.

There is no question but that there are times when a repeater control operator is unobtrusive and considerate and the repeater still gets jammed, but in every case I've heard personally, this was not the case. I've heard dozens of jammings of repeaters, but I've also heard some of the stuff that precipitated the jamming . . . usually a very arrogant control op who has made someone mad. In other cases, I've heard whole groups join in to aggravate a poor situation and make it impossible.

Something happens to many (if not most) people when they get power over others, even if it is so insignificant as being a net control or a repeater control operator. They seem to immediately forget what it is like for the other chap, and they start throwing what weight they have around. This often calls for retaliation . . . and we have jamming. I'd be surprised if 90% or better of the jamming hasn't been instigated by an officious operator who has a severe personality problem . . . like a well-deserved inferiority complex . . . who irritates someone else beyond their capacity of acceptance. Oh, I know the feeling . . . for instance, when someone comes on a repeater where I've been talking for a while and says in an official voice that it is an FCC regulation that I identify my station.

WHAT TO DO

For many amateurs, the first port in a jamming storm is a call to the FCC for help. Then they get all bent out of shape when they find that the FCC boys have better things to do than help us find some yo-yo we've irritated who is busy "getting even."

Speaking of nets, it may come as a rude shock and chilling news, but the FCC has a rule which is fairly explicit . . . no ham, or even net, has a claim to a frequency. The fact that a net has used the same channel daily for fifty years is not an excuse for running roughshod over any stations who are using it come net assembly time. I would suggest that one or two stations be designated to act as peaceful

LETTERS

GODBOUT

Recently, due to failure of one or more RAM chips in my TRS-80, which had been purchased from Godbout (Bill Godbout Electronics) 10 months previously, I returned all eight chips to Godbout under the terms of their one-year's warranty. I requested that they test these chips to determine which were defective and replace as required. I offered to pay for the testing, if necessary, as I was not equipped to do so.

I was pleasantly surprised to receive within a week a complete eight-chip RAM kit from Godbout—no charge whatsoever, and postage paid! Now, I am sure that all eight original chips were not defective and can conclude only that once again Godbout is performing in their characteristic "the-customer-must-be-pleased" manner.

This attitude will go far to ensure the future success of this outstanding supplier.

Agoura CA

DAVID

Here is some updated material regarding the emergency operation of the Florida Crown Net (Jacksonville) and the Florida Midday Traffic Net (FMTN) during hurricane David Sept. 2-5th.

Local Red Cross Director Buck Willocks of Jacksonville praised the amateurs saying, "If there was any one group who shined during the emergency, it was the amateur radio operators of this community." He was referring to the 55 operators who volunteered to link the 16 Red Cross evacuation shelters to Red Cross HQ. Personal commendation certificates are being given to each participant. In addition, stations were set up at Civil Defense HQ, the Weather Bureau, WTLV-Channel 12 studios, and the Mayor's office.

Jacksonville Mayor Jake Godbold and his staff also expressed their deep appreciation and it is reported that the Mayor will attempt to visit at least two local amateur clubs, The North Florida Amateur Radio Society (NOFARS) and the Jacksonville RANGE Assn., to express his thanks personally. City officials monitored the transmissions on two meters to get the latest evacuation count.

Telephone lines at Red Cross were completely jammed and the only communications were via amateur radio.

On the statewide level, complimentary reports continue to pour in concerning the operation of the Florida Midday Traffic Net on 40 meters (day) and 75 meters (night). The net stayed in session for over 55 continuous hours providing the only coverage of the entire state. At least three major Weather Bureau offices in Florida were linked together by FMTN.

Ironically, the FMTN was kicked out of the ARRL last month because, after 23 years of operation, they refused to accept the SCM's wish to dissolve the net administration and have all officers appointed by him. Please see the following for additional information.

Billy Williams N4UF
Assistant Manager, FMTN
Jacksonville FL

STATE ARRL OFFICIAL KICKS FLORIDA MIDDAY TRAFFIC NET OUT OF LEAGUE

On August 11th, ARRL South Florida Section Communications Manager (SCM) Woodrow "Woody" Huddleston informed Florida Midday Traffic Net (FMTN) Manager Al Suhr WB4AID that FMTN was no longer a part of the American Radio Relay League (ARRL).

In his letter, Huddleston gave no other reason for the revocation of the ARRL section of Florida's largest traffic net other than to say that the "FMTN does not qualify as either a section net or a local net in the ARRL National Traffic System. The net and its management have steadfastly refused to respond to the wishes of the ARRL Administration within this section. Therefore, I cannot justify expending ARRL funds issuing certificates to FMTN members," said Huddleston.

This last statement is considered enlightening because most FMTN members are ARRL members.

To summarize, after 22 years of operation, the FMTN was asked by Huddleston to hand over control of the net and the frequency to him last September. He said that he felt uncomfortable with so many nets operating in "his" section. The FMTN members voted 55 to 2 for rejecting Huddleston's demands.

Shortly thereafter, Huddleston was instrumental in establishing a new net just four kHz up in frequency at the same hour. Evidently, he was hoping to use his influence and the ARRL's prestige to lure FMTN members away since most FMTN members belong to the League. Most officials expected this to happen, but, surprisingly enough, the opposite occurred. The new net, called the Combined Florida Net (CFN), created more hard feelings by "clearing" its 7,251 kHz frequency at net time by just opening up on top of stations already in QSO. It seems that Huddleston and CFN underestimated the strength of those upon whom they tried to trample, because after two rocky ineffective months in which several sessions were cancelled, the CFN was forced to move just to survive.

Despite the move, CFN continued to falter as daytime traffic operators rallied behind FMTN and its democratic stand. FMTN has been the top net of any in Florida for the last 11 months running, based on official statistics in *Florida Skip*, in messages per session handled. The long anticipated wilting of FMTN was not to be, as many operators became incensed about losing their right to elect their own manager and not have it dictated by Huddleston. CFN went begging for traffic while people waited in line to pass messages on FMTN. A telephone campaign by some Florida ARRL officials to recruit CFN members also was a dismal failure.

When the latest *Skip* statistics showed FMTN on top again last month, it must have been more than Huddleston could take. After failing to get FMTN cut out of the national nets, he sent the letter expelling FMTN from the ARRL because they wouldn't let him take over.

For the 70 FMTN members, reaction was immediate. Included among the members are several club presidents and officers statewide. Comments ranged from "dumb" to "smacking of a dictatorship" describing Huddleston's action.

The big sting came last December when one member of the then-new CFN net was told by a North Florida ARRL official that he couldn't eat at 5 pm any more because he was needed to make the new system of nets work in conjunction with linking CFN with a later net. A lengthy shouting match occurred on the CFN frequency with the poor soul saying he just wanted to continue eating at 5 o'clock as he had done for the last 25 years. Fortunately, it's all on tape so it can't be denied.

We have no reaction from North Florida ARRL officials on Huddleston's mass ejection, but they have backed him up in the past to the point that some have said that the statewide policies are all made by Huddleston in Largo and rubber-stamped in the rest of the state. It will be interesting to see if this holds true now.

Meanwhile, Florida Midday Traffic Net officials have declared themselves an independent net whose members operate on the legal basis of their FCC licenses and not through the sanction of the ARRL. Meanwhile, the controversy continues about the tactics involved and daytime operators continue to support FMTN in growing numbers.

This may be one case where David rises up and slaps Goliath!

From NOFARS *Balanced Modulator*, September, 1979

DRIVEL

Although I have long been an admirer of you and *73 Magazine*, one who has enjoyed your growling and caustic comments, all of which put amateur radio on its toes, made us aware, and stirred amateurs into thinking for themselves, I wonder what has happened to *73* et al this past year. I am really doubting the values and goals some of your articles are exhorting. Also, it sure seems as if you are dumping the average amateur, the guy without the megabucks, for the manufacturer and big interests. Maybe you no longer need the individual ham as long as you have the big or seemingly big, the manufacturer, and the guy who calls building a ham station or minicomputer an assembly of components. It sure looks like the so-called builders merely plug in boards and equipment according to many of your articles (or build power supplies).

Another trend in *73* that is really disturbing has been Pasternak, and his trying to foist on us control of FM and amateurs by clique-appointed committees with power to have yea or nay over other hams. Let's leave California and its dubious means of operation on the earthquake side of the mountains. Also, I object to his begging support of HFers as he tries to tell us how wonderful they are.

Then we get articles on jamming police radar and the re-

Newhall CA 91321

On Saturday, September 22, 1979, it was announced that the nation's second oldest repeater, currently operating under the callsign WA6KOS/RPT on Mt. Wilson, would be permanently terminating operation on or about October 13. The announcement came in the form of a letter from system equipment owner/sponsor Burt Weiner K6OQK, in which it was stated that after 18 years of continuous operation, he had proven to himself that he could make a system function and do so at the extreme limits of the state of the art available. Further, that due to the increasing amount of willful and malicious interference, with him as a prime target of it on a personal level, he had reached the decision that it was time to terminate the operation and proceed in other directions.

The system now known as WA6KOS/RPT started life as WA6TDD in 1962. It was put into service as an open repeater and has remained such ever since. Dockett 18803 caused a callsign change in 1972 and WA6TDD became known as WR6ABE. In 1976, Burt Weiner bowed out of the responsibility of licensee of the repeater, turning that obligation over to Bob Thornburg WB6JPI. At that time, the system became known as WR6AMD. Some 10 months ago, Bob bowed out of the position of licensee and the reins went to David Faraone WA6KOS whose callsign now appears on the system. Throughout these latter years, Burt Weiner has remained as equipment owner and has maintained the system's high technical standards for the licensees who followed him.

In his letter to Faraone and the repeater's users (about 450), he stated that though he has tried to remain a disinterested party in the operation of the system, he could not, and with the increasing amount of personal abuse being hurled at him, he realized that the only way to solve the problem was for him to take the system out of service and disappear from the scene entirely. He hopes that, in time, those now abusing both him and his equipment will forget that he ever existed.

In commenting on the demise of WA6KOS, Faraone also stated his intention to establish a new repeater and to commence operation when Burt removes his system from service. The new repeater, again under the callsign WA6KOS/RPT, is to be located atop Santiago Peak in South Orange County at 5800' MSL. However, it is rumored, though not confirmed, that opposition to the new system from politically powerful remote-base owners who want no part of an open two-meter repeater on that hill is mounting. WA6KOS operates with a transmit frequency of 146.40 MHz. With 146.46 MHz being the recognized national remote-base intertie frequency, the remote owners fear that the overall ambient noise factor of the band will be raised by the new device and impede communications on .46. It should be mentioned that not all remote owners seem to feel this way. At least three have offered Faraone help in establishing the new system and technical assistance in clearing up any interference problems that might ensue.

Also unconfirmed are rumors that a number of major southern California repeaters, fearful that the same type of abuse that has caused the demise of KOS will descend on them, are planning to "private out" and turn toward selective usership operation. The political climate is viewed as being that should two or three major systems make this move, it would initiate a domino effect that would write an end to open repeater communication in the southwest in short order. More next month.

THE GOOD GUYS WEAR WHITE HATS DEPARTMENT

In the old western movies, the ones made in black and white and prior to the advent of television, it was easy to tell the hero from the villain. Heroes always wore white hats and rode white horses. Your friendly local neighborhood villain usually wore black clothing, a black hat, and rode a black horse. Maybe these were not the actual colors, but who could tell? You went to a flick to cheer the hero and hiss the villain. Wasn't it easy in those days?

Villains are not supposed to be good guys and vice versa. Unfortunately, something has run amok in our society that, at times, causes the tables to be turned. Suddenly, a villain appears to be a hero and is able to build support for a position that appears totally wrong to the majority. In a nutshell, this describes a situation now running rampant on many Los Angeles two-meter repeaters. A small but highly-vocal group of people have come to demand their "right" to utilize any form of language they may desire, regardless of how offensive such utterances might be to the rest of the area amateur community. They defy anyone, including the FCC, to stop them, claiming that any action in that direction would be a direct violation of their First Amendment rights. There even appear to be a few in this group who are not even amateurs, but who have amateur equipment and use it on the air. Their claim seems to be that since the "airwaves" belong to the "people," they have a right to operate a radio without subjecting themselves to the will of any government or agency thereof.

This group believes that anything goes, anything said is "right," and anyone they wish to abuse on the air is fair game. It is quite interesting that they only seem to inhabit busy wide-coverage open repeaters, where there exists a vast audience for their rhetoric. They rarely bother the smaller local systems, and I have yet to hear a report of them "taking on" a private repeater's usership, though many super-wide-coverage "privates" do abound. Two things are evident. First, to exist, they require a large audience to fulfill their egos, and second, they probably live in fear of the reprisals they might endure if they assailed a private system. It's no secret that the history of this area in relation to protecting one's domain, especially in regard to the sanctity of private repeaters, is one of retaliation for any such attack. So, they continue to feed their egos on the "average" amateur who operates on the "average" open repeater.

For many years, I have wondered how a situation such as this could possibly develop. Many theories have come forth, but few were very conclusive, and, until now, none offered any real solution. Recently, I had the opportunity to meet and speak with Russ Andrews K6BMG. Russ is not new to the amateur fraternity. He holds a General class license and has been a ham for over 25 years. Like myself, he has witnessed the move toward lawless operation and disrespect for the will of the majority by the aforementioned minority. He has taken the time to develop a short thesis on the subject that we now present for your approval and commentary.

LAWLESSNESS ON THE HAM BANDS

What follows is one man's opinion. It is based on over 25 years as a licensed ham and on my observations and understanding of human nature and foibles. In part, it takes the form of a scenario. Its purpose is to possibly give a wider view of the problems on the ham bands and stimulate thought, discussion, and, ultimately, a solution.

How Did We Get Where We Are?

1. There is, in society today, a general disrespect for government, bureaucracy, and authority.

2. The creation of the CB band resulted in such an explosion of personal radio activity that the FCC resources were overwhelmed. This inability to provide needed policing resulted in the "lawless" nature of CB the FCC is now struggling to overcome.

3. This CB lawlessness soon spread to the creation of HFers, operating on non-CB frequencies.

4. Many of these CBers and HFers found out about ham radio and moved up (either legally or by various illegal methods).

5. Other hams simply became corrupted, or fearless, and allowed their negative sides greater rein.

Why Has the Traditional Self-Policing of Ham Radio Failed?

Self-policing is based on three things:

1. Respect for the privileges and for others who have earned similar privileges. This factor has been weakened in several ways:
   - •Eased entry requirements.
   - •Examinations "given" by other hams—and falsified.
   - •Bootleggers.

2. Peer pressure. The new breed of offender is immune to peer pressure from the general ham fraternity.
   - •They have a different set of values.
   - •There are enough of them now to form their own subculture, or peer group, that *supports* them in their lawlessness.

3. Fear of exposure. They have built a rationalization which convinces them that they are in the right and the rest of the fraternity is wrong. So, why should they be afraid of being exposed, if they believe they are right? In addition, the prevailing opinion is that even if exposed to the FCC, the FCC will do *absolutely nothing*; therefore, why should they fear being "turned in" by other hams?

Where Are We Now?

We have a growing group of antisocial, lawless individuals whose governing force is an ego-driven desire to have power through the use of radio technology. This group is self-stimulating, that is, it encourages within itself increased technical competence toward jamming

Continued on page 224

The following are excerpts from unsolicited letters and registration cards received from owners of the new TEN-TEC OMNI transceiver.

"I sold a Yaesu to buy this and am very impressed" —*WB5ULA*

"My first QSO with OMNI-A was LA1SV on CW and second was EA8SK on SSB." —*N2CC*

"Excellent rig, just as advertised." —*WB5TMD*

"Very pleased with performance. QSK feature very slick." —*WB0ELM*

"This is my 5th TEN-TEC transceiver in less than 2 years. I loved them all and still have 3." —*WB0VCA*

"Through the years I have had complete Drake and Collins stations. I tried a 544 Digital and liked it the best so decided to purchase the 546 OMNI-D Digital." —*WA4NFM*

"Your OMNI is the best rig I have had in 20 years of haming." —*K4IHI*

"As a owner of Collins rig, your OMNI-D is the best." —*K9JJL*

"I already have an OMNI-A, 544 and a TRITON IV. You may ask why I own so many TEN-TEC rigs. In case there is a great RF famine, I want to be ready!" —*WD4HCS*

"You guys really know how to turn on an old timer!" —*K8ELS*

"Best operating & most conveniences of any transceiver I've ever used." —*W6LZI*

"I like CW. Compared OMNI against IC701 (rcvr) and OMNI won hands down. XYL WD6GSB really enjoys rig on SSB. Finds rig is very stable and digital readout accurate." —*AC6B*

"Have checked it out on both modes from "top band" (160) all the way to 29 MHz. Terrific!!!!" —*W4DN*

"Works well, parts layout and design much better for any possible servicing than other ham gear. The Japanese hybrid sets can't compare to TEN-TEC for audio. Audio reports excellent without special speech processors, etc., to distort the signal." —*AG8K*

"I have been using the S-Line over 15 yrs and never thought anything could outperform it. I got the biggest surprise and THRILLED with this OMNI-D even though I have been a ham since 1936." —*KV4GD*

"This must be the greatest. I've spent enough money on final tubes to almost pay for this." —*KA4BIH*

"This transceiver was recommended to me by old time hams (Xtras) whom I have known for 40 yrs. Has excellent break-in." —*N6AVQ*

"Best package job I've ever seen! First licensed 6AAV in 1926. Now in operation—a sweetheart!" —*W7LUP*

"From a 32V2/SX115 to an OMNI is a big step!" —*K6YD*

"Receiver prominent—transmitter likewise—working comfortable—pleasing design." —*OE1FAA*

"First new rig for me in 10 years but seems to be very good." —*W5GBY*

"The best transceiver I ever used or owned." —*W3TS*

"I wouldn't swap my OMNI for anything on the market, regardless of price." —*WD0HTE*

OMNI/SERIES B FEATURES

All solid-state; 160-10 meters; Broadband design; Standard 8-Pole 2.4 kHz Crystal Ladder I-F Filter + Optional 1.8 kHz SSB Filter & 0.5 kHz 8-Pole CW Filter; 3-Bandwidth Active Audio Filter; Choice of readout — OMNI-A (analog dial), OMNI-D (digital); **Built-in VOX and PTT, Selectable Break-in, Dual-Range Receiver Offset Tuning, Wide Overload Capabilities, Phone Patch Interface Jacks; Adjustable ALC; Adjustable Sidetone; Exceptional Sensitivity; 200 Watts INPUT; 100% Duty Cycle, Front Panel Microphone and Key Jacks; Zero-Beat Switch; "S"/SWR Meter; Dual Speakers; Plug-In Circuit Boards; Complete Shielding; Easier-to-use size:** 5¾"h x 14¼"w x 14"d; **Full Options:** Model 645 Keyer $85; Model 243 Remote VFO $139; Model 252MO matching AC power supply $139; Model 248 Noise Blanker $49; Model 217 500 Hz 8-Pole Crystal Ladder CW Filter $55; Model 218 1.8 kHz 8-Pole Crystal Ladder SSB Filter $55.

Model 545 Series B OMNI-A . . . $949
Model 546 Series B OMNI-D . . . $1119

To add your name to the fast-growing list of OMNI owners, see your TEN-TEC dealer, or write for full details.

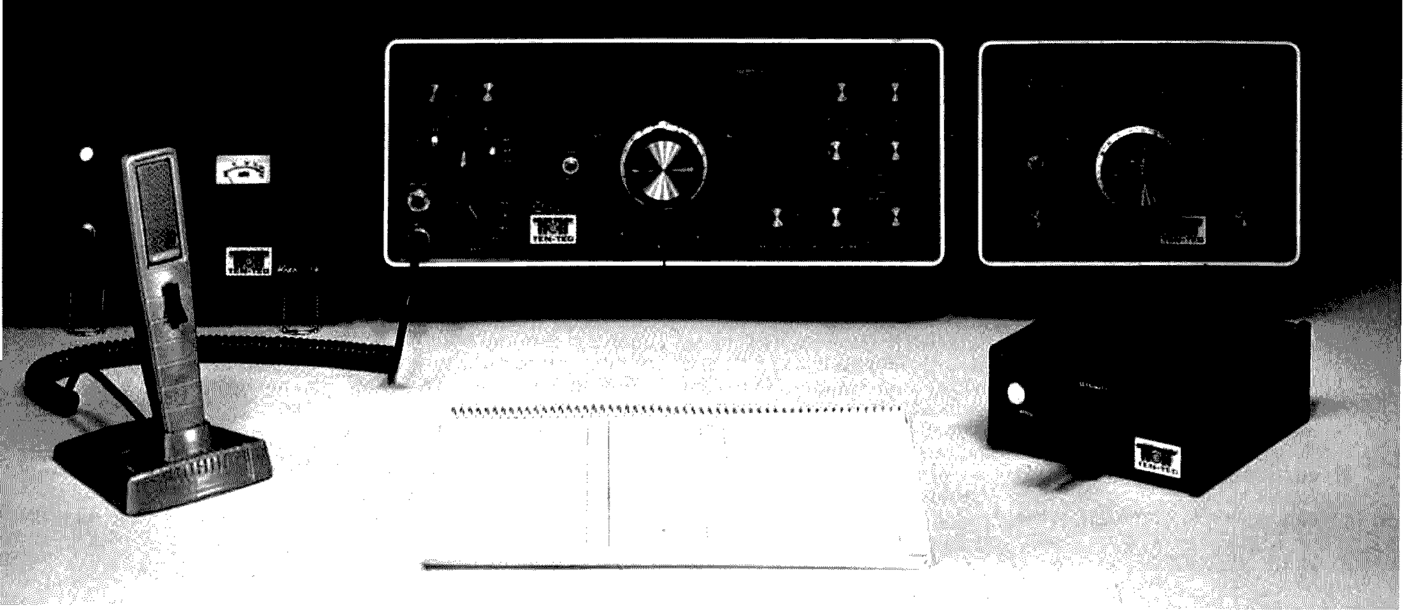
OMNI OWNERS SAY:



RTTY Loop

Marc I. Leavey, M.D. WA3AJR
4006 Winlee Road
Randallstown MD 21133

I made a mistake. Now, now, don't try to talk me out of it or minimize it. I made a mistake! Let's call it an error of omission. You see, a few months ago I listed articles on "silent RTTY," grouped by system types. I said that the list was complete. Well, I was only partially right; I inadvertantly left out reference to articles appearing in *73*'s sister magazine, *Kilobaud MICROCOMPUTING*.

Fig. 1 is an attempt to correct this error. As you can see, several types of articles have been published in *Kilobaud MICROCOMPUTING*, encompassing many computer families. Rather than list them strictly by type, the figure includes a brief statement on each article's content so that you may guide your search accordingly.

Interest in microcomputer-assisted RTTY is running quite high and clearly constitutes the majority topic in mail received. One correspondent, Victor C. Johnson from Minneapolis, Minnesota, is interested in the Heath H-8 RTTY program. I hope the program printed in the June, 1978, issue of *Kilobaud MICROCOMPUTING* is of use to him.

Victor also is looking for a Teletype™ Model 28, receive only, and is apparently having a hard time finding one in the Minneapolis - St. Paul area. Anyone in that region who might help him is asked to drop a line to him, in care of this column; I will forward it along to him. As far as commercial sources go, Victor, we have covered several sources in the past, but, as always, checking with local hams for reliable sources is the best way to go.

I have been quite upset over the number of complaints received about several of the known firms dealing with Teletype equipment. While most of the complaints center around unanswered inquiries (several of which I have also suffered) or prolonged shipment times (ditto), there is also the occasional, as pointed out over the past few months, paid-for order which is never heard from again. Incidentally, no work yet on the problem source noted last month.

Dave Phillips W7GZ writes that he will be coming up on the air soon with a Kleinschmidt machine and home-brew TU. This is to be replaced in short order by a 6800 microprocessor system and CRT terminal. Quite an order of magnitude difference! Dave is in need of wiring diagrams or maintenance manuals for his Kleinschmidt model TT-99. He notes that he has Teletype Model 28 ASR/KSR data available for the costs of postage and reproduction. If anyone is interested, contact Dave at 802 S. Eli Drive, Tucson, Arizona 85710.

A letter received from Wayland Osborn WØRRG poses a "big question." Wayland asks, "Are you aware of any RTTY gear, other than the Microlog system, which can be used to key the Kenwood TS-820 in transmit utilizing its built-in FSK feature?" My first inclination is to suggest using one of my favorite devices, a reed relay, in the loop to key the transmitter. It occurs to me, however, that you may be using only a CRT setup, without a conventional loop. In that case, you would have to adapt some form of on-off switching to the system, and I can appreciate your problem. Readers with similar systems are invited to drop a line and tell Wayland, and all of us, how *you* solved it!

Wayland also touches on the reported rf sensitivity of the Microlog system and my note last year that information promised me was yet to be seen. Well, as of this writing, one year has passed, and I still have received zip. This is not unique to Microlog, however. In fact, several companies, visible and well advertised, have promised to send various data sheets and literature in the past; not one has followed up on the offer. I don't know why—oh, well!

The final letter this month comes from Jim New WA4DHD, a newcomer to RTTY, as he puts it. Jim is using the TRS-80 with a Model 19 for hard copy and is having great fun on the air. He wants to know where most RTTYers hang out. Well, starting on 80 meters, you might try 3620 kHz, and 14080 kHz on 20. Forty-meter RTTY is an iffy thing, and other bands frequently depend on conditions. Twenty and 80 are pretty well populated, and a QSO is almost always available.

Yes, I do have a station, for those of you who have asked, but I have not been on the air much. I promise to try, so that those of you who think that I am but a pseudonym for Wayne Green will learn better. I know that I exist, and I hope to be more visible.

March, 1977—"Using The '$50' Terminal," James Brown. The author presents, in flowchart fashion, ASCII-to-Murray conversion. No particular microprocessor is mentioned.

November, 1977—"SC/MP Goes Baudot," Benjamin Blish. An SC/MP microcomputer is used to interface a Murray machine to an SWTPC 6800. Both software and hardware are presented.

June, 1978—"Baudot . . . er . . . Murray, Meet The H8," Howard L. Nurse. Interfacing to the Heath H8 is covered with full source listing and hardware needed. A solid article.

June, 1978—"ASCII to Baudot . . . er . . . Murray (the Hard Way)," John A. Lehman and Ray Graham. A tale of an experience with one supplier's conversion board.

September, 1978—"Baudot Interface Cookbook," J. R. Haglund and W. B. Reed. A scheme for interfacing to an 8080 based microprocessor. A note states that the program has been tried on and runs well on a Z-80 system.

August, 1979—"Teleprinter Output for TRS-80," David G. Morr. A hardware and software scheme for using a Murray-encoded printer as an output device. Full listings and hardware are covered for this Z-80 system.

September, 1979—"Make PET Hard Copy Easy," Dr. James M. Downey. Interfacing both ASCII and Murray-encoded machines to the PET IEEE bus through use of a UART and specially encoded ROM. This is a hardware modification with no software requirements. The machine is used strictly as a printer.

Fig. 1. Articles from Kilobaud MICROCOMPUTING *on computerized RTTY.*

Corrections

In my article, "Dual-Band Smokey Detector," which was published in the May issue, two errors in the drawing dimensions slipped by me when I reviewed the proofs.

On page 49 of that issue, the last paragraph calls for the circular waveguide to be made from ½-inch water pipe. It should be ¾-inch water pipe.

The dimensions shown on the rectangular waveguide E plane view on page 51 should show the hole for the circular waveguide as 7/8 of an inch in diameter (or the outside diameter of a piece of ¾-inch copper water pipe). The horn mounting hole is also shown as ½-inch; this descrepancy can be easily rectified by making the tab cuts deeper so that they can be bent to fit the o.d. of the circular waveguide. All hole cuts into the circular waveguide retain the same dimensions. One thing not described in the article, however, is the fact that the WR42 guide must be trimmed on the inside of the circular guide to be flush with the inside wall of the pipe.

I have also received many calls regarding the omission of the value of the series resistor shown where the 12-volt feed is located; this resistor is rated at 10 Ohms. It connects to the junction point where it feeds the main dc into the two 741 ICs and a 390-Ohm resistor. The point marked +12 volts on IC5 should also tie to the same junction point since that resistor serves as part of the filter from the source.

I have found a supplier for waveguide and other microwave components where amateurs can get small quantities. This supplier has an excellent catalog and offers it to the public for the asking—no microwave experimenter should miss it. The company is Lectronic Research Laboratories, Atlantic and Ferry Avenues, Camden NJ 08104. Ask for Sales Bulletin 107.

Waltham MA

Ham Help

I was an amateur, but lost my license because I could not construct my own transmitter and operate. I am trying to again get my license, but also I am badly in need of some equipment to continue with my other experiments. Unfortunately, this equipment is not available in India.

If anyone can send me construction details, along with circuit diagrams, etc., of a Van de Graaff electrostatic generator, a Wimshurst electrostatic generator, and biofeedback machines, I would be most grateful.

Any names of books and their publishers, from whom I can buy those books, also would be appreciated. Thank you very much.

Awards

Bill Gosney WB7BFK
2665 North 1250 East
Whidbey Island
Oak Harbor WA 98277

This past fall we announced for the first time our new amateur radio awards program. Featured in a two-part series in the September and October issues, we outlined a total of eight *73 Magazine* achievement awards available to amateurs the world over. Since then, letters of support have been received from all parts of the globe, each showing dedicated interest in pursuing the challenges our awards program has to offer.

This month, we offer two new awards, each of which is very unique in its own right.

THE Q-5 AWARD OF EXCELLENCE

This award, sponsored by the editors of *73 Magazine*, is available to amateurs throughout the world possessing any class license who operate periodically in the American Novice band.

To be valid, all contacts must be made on or after January 1, 1980. Likewise, all contacts must be made using only the CW mode on those frequencies assigned to the American Novice. Maximum power allowed will be limited to 250 Watts input. There are no band restrictions for this award.

To qualify, the applicant must work all ten US call districts and receive no less than a Q-5 report. A qualifying RST might be, for example, 559, 539, 579, etc., while an RST of 449, 349, 479, would not qualify the applicant for the award.

This award is not meant to be an overnight accomplishment. Stations meeting the challenge of these requirements will be proud to display this unique award depicting the excellence and superiority of their station's transmitted signal.

To apply for this award, the applicant must prepare a list of all claimed contacts, logging each contact in order of the US call district. Indicate the station worked, the date and time in GMT, the frequency utilized, and, most important, the RST report as noted on your confirmation card. Also required is a brief description of the station equipment and antenna system used to complete this award.

Do *not* send QSL cards! Have your list verified by two amateurs, a local radio club secretary, or a notary public. Enclose your verified list along with the award fee of $3.00 or 8 IRCs to: Bill Gosney WB7BFK, 73 Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island WA 98277 USA.

A significant number of amateurs throughout the world find their primary interest in the operation and development of specialty-type communications. It is the efforts of these many pioneers in their field which have created many state-of-the-art improvements which we know today. The editors of *73* wish to recognize those amateurs who make positive steps toward expanding the use of their respective mode or type of amateur operation. As a result, in the paragraphs to follow, you will learn of our latest communications award dedicated to "communicator specialists."

SPECIALTY COMMUNICATIONS ACHIEVEMENT AWARD

Sponsored by the editors of *73*, this award is dedicated to amateurs worldwide who take pride in active participation in the field of specialty communications.

To be eligible for this award, some very rigid requirements must be met. First of all, contacts must be made on or after January 1, 1980. In addition, only communications via SSTV, RTTY, EME (Earth-moon-Earth), and/or OSCAR will be recognized for this award. Contacts between stations on OSCAR or EME may be made using any mode authorized in your country. Applicants must be cautioned, however, that mixed-mode contacts will not be valid.

This award will be offered in two levels of operating achievement, each a worthy award in itself:

Class A requires applicant to work all 50 US states.

Class A-1 requires applicant to work a minimum of 10 DX countries from the WTW DX Countries List.

To apply, the applicant must prepare a list of claimed contacts. For the Class A award, this list must be arranged in alphabetical order by US state; for the Class A-1 award, prepare the list of contacts in order by callsign prefix. Either list must also include the date and time in GMT, the band and mode of operation, and a signed declaration of the type and description of equipment and antenna systems used to make your contacts.

Do *not* send QSL cards! Have your list verified by two amateurs, a local radio club secretary, or a notary public. Enclose each list with an award fee of $3.00 or 8 IRCs to: Bill Gosney WB7BFK, *73* Awards Editor, 2665 North 1250 East, Oak Harbor, Whidbey Island WA 98277 USA.

Should any readers of this column care to possess our new awards program booklet, you are urged to send for your free copy now while the supply lasts. The only requirement is that you send a large business-size SASE when making your request. At the same time, I would like to encourage you to write any comments you may have about this column or our awards program being offered.

Traveling abroad as we do every month, I wish to share a very unique series of awards being offered by the Swedish Amateur Radio Society (SSA—Sveriges Sandareamatorer).

Karl Friden SM6ID wrote to inform us about the WASM II achievement award and sent along this very attractive diploma which is issued upon successful completion of the award requirements.

WORKED ALL SM LAENS WASM II

The WASM II, awarded by SSA, is available to amateurs throughout the world. Class A is for amateurs located in those countries with prefixes LA, OH, OZ, and SM. The Class B award is for amateurs in the rest of the world.

To be valid, all contacts must be made January 1, 1953, or after. Any one of the amateur bands is allowed and contacts made in CW or phone or any combination of both are allowed, providing it is not cross-mode.

Amateurs in Class A areas must submit proof of having established two-way communications with each of the 25 laens (counties) on two different bands (50 QSLs). Amateurs in Class B areas must submit proof of having established contact with each of the 25 laens without any band restrictions.

Sweden is divided into 25 laens or counties:

A—City of Stockholm (SM5 and SM0)
B—Stockholm laen (SM5 and SM0)
C—Uppsala laen (SM5)
D—Södermanland laen (SM5)
E—Ostergötland laen (SM5)
F—Jönköping laen (SM7)
G—Kronoberg laen (SM7)
H—Kalmar laen (SM7)
I—Gotland laen (SM1)
K—Blekinge laen (SM7)
L—Kristianstad laen (SM7)
M—Malmöhus laen (SM7)
N—Halland laen (SM6)
O—Göteborg och Bohus laen (SM6)
P—Älvsborg laen (SM6)
R—Skaraborg laen (SM6)
S—Varmland laen (SM4)
T—Örebro laen (SM4)
U—Vastmanland laen (SM5)
W—Kopparberg laen (SM4)
X—Gavleborg laen (SM3)
Y—Vasternorrland laen (SM3)
Z—Jamtland laen (SM3)
AC—Vasterbotten laen (SM2)
BD—Norrbotten laen (SM2)

Application for the WASM II must be accompanied by a verified list of claimed contacts. This list may be verified by two amateurs, a local club secretary, or a notary public. Enclose this list with 7 IRCs or US stamps of equivalent value and send to the attention of: Karl O. Friden SM6ID, Awards Manager SSA, Pl. 1084, Morup, 310 56 Langas, Sweden.

And, while speaking of the Swedish Amateur Radio Society, I received a very nice letter from Kjell Edvardsson SM0CCE who is awards manager for the WASM I award being offered by this national organization. It is very unfortunate that a sample of this award is not available for reproduction. This is due to the fact that the award is a very large cloth depicting scenic highlights of this beautiful and picturesque country and personalized to display the identity

Leaky Lines

Dave Mann K2AGZ
3 Daniel Lane
Kinnelon NJ 07405

Some irritations are of great importance; others are of relatively less concern. Since it is in the very nature of the incorrigible malcontent to nitpick, I decided a long time ago to leave significant questions for others to discuss. I deal with those niggling little matters that produce heartburn rather than peptic ulcers. If you seek the earth-shattering exposé, the juicy scandal, or the noble crusade, move on; you will not find it here. Let others pursue man-eating sharks and tigers . . . I swat flies and mosquitoes.

A case in point: Here, I think, is one of those small insanities that's right up my alley. It calls for some protest, however slight. I would have hoped that Newington, Connecticut, would have registered some opposition, but none was forthcoming. There are times, I suppose, when the lamb will willingly lie down with the lion.

The present system of callsign allocations is an abomination. It more closely resembles some sort of random selection than a structured plan which could clarify grade of license, seniority, or geographical location. The unfortunate inclusion of a great number of garbled prefixes has botched up the whole thing but good.

There is no longer any dependable way, short of asking directly (which somehow goes against the grain), to know whom you are working or whether your contact has been licensed for sixty years or for sixty days. It is claimed that this arrangement will tend to democratize the ham bands, but it will not. It will merely produce an element of uncertainty in an area once highly organized. One used to know beyond peradventure that the KA he hooked up with was a member of the U.S. military stationed in Japan; now he may be some guy right around the corner . . . there's no way to tell just from the prefix.

I'm not disturbed merely by the confusion. I simply dislike the idea of creating equality where it really has no place. Don't misunderstand me. I am one hundred percent in favor of political, racial, sexual, and social equality . . . a true advocate and champion of democracy. But it has no more place in ham radio than it has in any other such avocation . . . photography, stamp collecting, gardening, woodworking, astronomy, or Sunday painting. What is this sudden impulse to create equality everywhere? I believe that those who have been around for a very long time deserve to flaunt the distinction to some extent. No human endeavor in which skill is a factor should be subjected to some artificial leveling process. I speak not of reward, but of simple recognition. And if this should happen to consist of a distinctive callsign, as it used to, what's so terribly wrong with that?

The simple truth is that, in the words of an old adage "When everybody is somebody, nobody is anybody."

By all means, reward diligence, talent, and industry. But not by taking something away from somebody else. They've now removed the distinction of the preferred callsign, the only thing that differentiated the oldtimer from the Johnny-come-lately. I rise to my hind legs and bay loudly at the moon. The new callsigns are lousy!

But things might have been far worse. I read a proposal that would have utilized the 3-letter, 3-digit system presently employed in the assignment of some state's auto license plates. If our present callsign system is bad, that one would have been infinitely worse. Some other joker got the brilliant idea that because Social Security numbers, like snowflakes and fingerprints, are unique . . . no two alike . . . they should be used to replace the standard callsigns. Don't expect me to analyze the logic that prompts such suggestions; I'm no expert in abnormal psychology.

It may be that the present revision of the callsign structure was designed for the convenience of the FCC monitoring stations, so that they could more easily determine who may be operating illegally in the restricted subbands.

This notion presupposes that these monitors are doing a conscientious job of policing in the first place . . .staying on top of the situation and nailing violators with swift efficiency. But they are not. A recent incident confirms the very opposite. The monitor at Anchorage, Alaska, issued notices of violation to a number of amateurs who had contacted Thailand stations. Obviously, the monitor labored under the mistaken impression that there still exists a banned countries list.

We have not had such a list for a very long time. This misadventure reminds me of the great flap that occurred when police were issuing summonses to hams who were transmitting while driving, despite a change in the law. This took place some fifteen years ago, and notwithstanding the repeal of the measure which had formerly prohibited such transmissions, these misguided minions of the law were highly reluctant to accept the change. Hams were advised to carry copies of the new regulation so they could show them to arresting officers. Despite all this, there are still some cops who attempt to hand out tickets to this day! To be sure, such cases are thrown out of court. But those who receive the summonses must answer them . . . a needless inconvenience. In like manner, those who have received these notices of violation from the FCC are being penalized. They have been informed that they "must respond to the citation in the manner outlined in 97.137, and the reply must be sent via registered or certified mail." (See *QST*, August, 1979.)

What would happen if one of these cited amateurs were to fail to reply to the notice? Bureaucratic conceit and self-conferred omnipotence being what they are, it would not be at all strange if they were to face actual revocation of license. Such is the nature of bureaucracy . . . agencies of the government are known to foul up from time to time.

Not only do these erroneous citations demonstrate that a bureaucracy can be wrong, but they also confirm a persistent conviction held by many that even when they are wrong, they pretend that they are right, and they insist upon having everyone else take part in the pretense, too.

Would it have been so embarrassing for the FCC to have issued a simple statement to the effect that all persons who had received the citation should simply ignore it? Why couldn't they acknowledge that there had been an inadvertent human error? Would this have been such a terrible humiliation?

It appears that the Commission is committed to the perpetuation of a grand illusion; it must maintain an aura of infallibility. Perhaps even more important, licensees must constantly be made aware of the awesome power of Big Brother.

Phooey and double phooey!

If the FCC were one-tenth as capable as it would have us believe, it would long since have succeeded in cleaning up the horrendous mess on CB . . . it would have been able to do something significant about the "woodpecker" that has plagued and bedeviled operations on the DX bands . . . it would have been able to nail all the CW intruders on fishing trawlers who constantly appear on unauthorized frequencies within our allegedly sequestered portions of the amateur spectrum. It would have been able to deal with the problem of unauthorized linear amplifiers on 27 MHz without having to eliminate 10-meter capability from amplifiers intended for use among legitimately licensed amateurs . . . it would have been capable of devising some nationally applicable regulation which would, once and for all, take uncompromising precedence over community zoning restrictions on radio tower installations. It would also have been able to force manufacturers of home entertainment devices to install adequate filtering so that TVI and BCI would be minimized, if not eliminated altogether, thus lifting the burden of ostracism and public condemnation from the shoulders of thousands of blameless amateurs and placing it where it rightfully belongs.

The fact is that there's nothing perfect in this all-too-imperfect world. But this has its compensations. It's great for the likes of me . . . a guy who derives personal satisfaction in pointing out foibles and flaws. How could I function if this were a world without faults? Yet, somehow I have the feeling that even if it were perfect, we grumblers and groaners would still manage to find something to gripe about.

Ham Help

I need a parts list and assembly and tuning instructions for a Telrex TC-99 triband beam antenna. Will copy and return.

A. McGinnis WA2DTQ
55 Patton St.
Iselin NJ 08830

I am in desperate need of a schematic and alignment instructions for a National NC-300. I would really appreciate any help.

Bob Amos
607 N. Madden
Shamrock TX 79079

I would like some help in studying for the General exam. Any person or group in the Bronx area interested in helping me?

Microcomputer Interfacing

David G. Larsen
Peter R. Rony
Jonathan A. Titus
Christopher A. Titus

The characteristics of the Intel 8253 programmable interval timer were introduced in our October column. This 24-pin chip is very useful in counting and timing operations. This section will discuss two test programs for the 8253. One is a demonstration program that illustrates the various modes of operation of the timer, and the other is a program that demonstrates the reading of counter data "on the fly."

The counter is wired to an 8080A-based microcomputer, as shown in our October column. The details of the test circuit are provided in Fig. 1. Although the use of an oscilloscope is handy to monitor output signal OUT0 from counter #0, it has been found just as useful to provide a single 7490 decade counter chip to detect negative-edge transitions at OUT0. The 25-kHz input clock frequency, which has a period T of 40 μs, is input at CLK0.

Before the 8253 chip is used, the nature of output signal OUT0 must be understood as a function of the six different modes of operation, MODE 0 through MODE 5. We have found the manufacturer's literature to be somewhat confusing, so their diagrams have been simplified by omitting all signals other than OUT0. This permits all six modes to be compared simultaneously, as shown in Fig. 2. Note that MODES 0 and 1 provide a negative monostable clock pulse of duration NT; MODE 2 provides a series of negative clock pulses of pulsewidth T and period NT; MODE 3 provides essentially a square wave of period NT; and MODES 4 and 5 provide a single strobe pulse of pulsewidth T at a time NT after a trigger pulse has been applied to counter #0. The quantity N is a 16-bit timing byte initially loaded into counter #0. In our program, the timing byte is 000 000, which corresponds to the decimal number 65,536.

At this point, it is appropriate to comment on the two possible actions of the GATE0 input:

1. GATE0 functions as a *gating* input; when at logic 0, pulses input at CLK0 do not reach counter #0 and no counting occurs. This type of behavior occurs with MODE 0, MODE 2, MODE 3, and MODE 4.

2. GATE0 functions as a *trigger/reset* input; a positive-edge transition at GATE0 resets counter #0 and initiates counting. Each time there is a positive edge at GATE0, counter #0 is reset. This type of behavior occurs with MODE 1, MODE 2, MODE 3, and MODE 5.

These different actions can best be observed with the aid of a counter and a value of NT in the range of 3-10 seconds. In our case, N is 65,536 and T is 40 μs, so $NT = (65{,}536)(40 \times 10^{-6}) = 2.62$ seconds.

The program used to test the 8253 chip is provided in Table 1. Note that we have employed memory-mapped I/O, in which the control register has an address of 200 003 and counter #0 has an address of 200 000. The program is quite simple. First the control word 060 (MODE 0) is output into the control register. Next, we successively load the LO and HI counter bytes, both of which are 000, into counter #0. Finally, we enter a wait loop. Table 2 in the October issue shows that a control word of 060 means that counter #0 is chosen; the least-significant byte is loaded first, then the most-significant byte. Observe

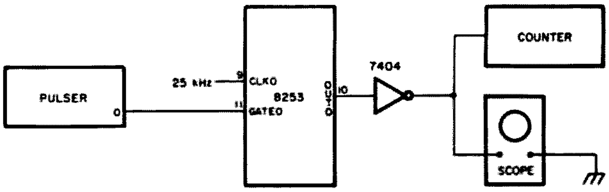

Fig. 1. Circuit for counter #0 on the 8253 timer to be used with the demonstration program given in Table 1. It is assumed that the counter counts negative-edge transitions.

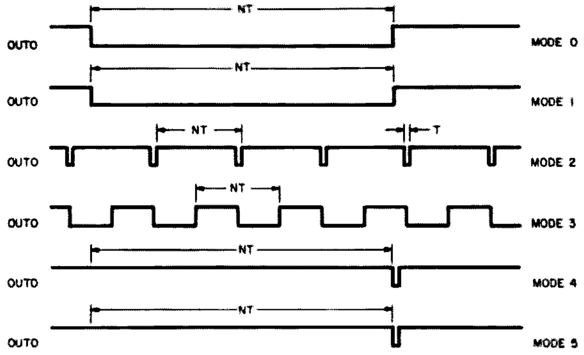

Fig. 2. Timing diagrams for the OUT0 output signal for each of the six operating modes of the 8253 timer.

the MODE 0 operation of the counter and count down in binary.

When executing this program, observe that OUT0 goes immediately to logic 0 and remains at this logic state for NT seconds, after which it returns to logic 1. This behavior can be repeated only by executing the program a second time, starting at memory address 003 000.

If the control word is changed at location 003 001 to 062 (MODE 1), the execution of the program begun, and the pulser

DX

DXPEDITION TO MT. ATHOS BY SV1DC, SV1IW, AND SV1JG

This expedition to Mt. Athos was the outcome of long discussions with the community of the Holy Mountain and great efforts on the part of all concerned. The operators were notified on July 20, 1979, that they would be permitted to transmit from Mt. Athos; they departed Athens on Monday, August 6.

SV1DC drove twelve straight hours, and the group was on the air at 1430 UTC, August 7. Since getting to the operating spot involved walking and hand-carrying, only a 12AVQ Hy-Gain vertical was taken; no antennas were available for other than 20, 15, and 10 meters. A Kenwood TS-520 with external remote vfo and a Honda E300 generator rounded out this field operation.

In 70 hours, over 8000 contacts were logged, including a thousand on CW by SV1IW. Most operation was on 20 and 15, with 10 meters being its usual obstinate summer self. In general, conditions were OK except toward Asia—only a few stations from Asia got through.

The Mt. Athos operation shut down at 0200 UTC on August 11; SV1IW and SV1JG along with SV1KP (Ms. SV1IW) proceeded to the island of Crete for a "vacation-style" expedition. In ten days, the three made 6000 more contacts, including many by Natasha, who signed SV9YL. During this period, propagation reversed itself, with conditions being better toward Asia than to North America.

The operators of this Mt. Athos and Crete expedition express their appreciation to all who called in and made their trip a successful one. We, in turn, thank them for putting two new countries in so many logs around the world.

On Crete (l-r), SV1IW, SV1KP, and SV1JG.

SV1IW works SSB from Mt. Athos, while SV1DC observes.

NOVICE CORNER

Let's talk about the perennial Novice, the one who never seems to learn. This is a rare case, actually, as most amateurs advance to being reasonably competent operators as they gain experience. Today's topic is how to work through a pileup on CW while causing minimal interference to others.

This morning, VQ9MR was working the US on the long path at 14,036 kHz, using relatively high-speed CW. The stations he was working were all about one kHz higher in frequency. That is, VQ9MR was "listening up one" without saying so, enabling those who grasped the pattern to easily have a quick QSO. One poor K4 station insisted on calling exactly on VQ9MR's frequency, which was bad enough; that same K4 also seemed inclined to transmit at the worst possible times, like when VQ9MR was also sending. What boggles the mind is that our K4 friend has been a ham for over twenty years! It was 8:00 am, so maybe he was asleep at the key?

First, our K4 person slowed down the whole operation by causing many to miss their report from VQ9MR; indeed, often one could not hear the Chagos come back through those still calling. This is not an uncommon problem. But if one particular K4 caller had had his act together, with the strong signal he had, he surely could have worked the DX on one or two calls, and he would have been gone, instead of fouling up the works for a long period of time.

The procedure for handling a situation such as this is simple and the rewards are great, especially with an excellent CW operator like VQ9MR handling the pileup. The goal, of course, is to transmit to the DX off fre-

New Products

SWAN ASTRO 150 SSB TRANSCEIVER

Swan is back! After a several year hiatus, during which little was heard from the company, Swan has returned to amateur radio with an impressive array of all-new, state-of-the-art equipment.

Swan, for those who have short memories, was a dominant force in amateur gear in the late '60s and early '70s. I was one of thousands of young hams of that era who yearned to own a Swan rig, but my high school and college finances never gave me that opportunity. That's one reason I jumped at the chance to put one of Swan's new breed, the Astro 150 SSB Transceiver, through its paces.

The Astro 150 bears scant resemblance to the transceivers of that earlier time. If you haven't shopped for an allband rig in the last five or ten years, you'll be amazed at just how compact and convenient they are.

General Description

The Astro 150 is a five-band SSB and CW rig covering 10-80 meters. A sister model, the Astro 151, covers 15-160 meters. The frequency coverage on each band extends well beyond the upper and lower limits of the amateur allocations, making the 150 a fine choice for MARS operation. With the bandswitch in the 20-meter position, for example, the transceiver tunes from 13.8 to 16.0 MHz. The other bands offer a similar overlap.

While the 150 is designed for SSB and CW operation, the owner's manual advises that SSTV and RTTY operation is possible if you take precautions. It recommends providing a small cooling fan for the heat sinks of both the transceiver and its power supply. In addition, the mike gain control should be used to reduce output to 50 Watts or less. A rear panel RCA jack is provided for inputting AFSK or SSTV signals.

Inside the 150

This transceiver is a ruggedly built modular rig. Virtually all components, including most of the front-panel controls, mount on printed circuit boards. Connections between the boards are mostly of the plug-in variety, so removing a board for service should not be difficult. A profusion of heavy metal brackets and plates provides rf shielding as well as mechanical rigidity. My lone reservation about the construction of the 150 is that a few of the metal brackets inside the rig have sharp edges which *might* erode the insulation on nearby wires. Admittedly, this is a minor point, as an enormous amount of abuse and vibration would be necessary for such damage to occur. A couple of well-placed pieces of plastic tape would set my mind completely at ease. Unless you plan extensive mobile and portable operation with your Astro 150, it is not cause for concern. This rig will last.

Swan's Astro 150 SSB Transceiver.

Despite its small size (3.75" H x 9.75" W x 11.75" D), the 150 weighs in at a hefty 13 pounds. The companion PSU-5 Power Supply/Speaker is of similar size. Both the transceiver and its power supply have their own on-off switches, a nice feature for those who don't like to connect a "hot" lead to any piece of equipment.

With few exceptions, there is no shared circuitry between the receiver and transmitter. The receiver is a single-conversion design with a 9-MHz i-f. The claimed sensitivity is .35 uV for 10 dB (S + N)/N. For CW operation, a 300-Hz i-f filter can be selected, or you can opt to use the SSB filters.

The transmitter is of a broadbanded design with an output power of 100 Watts PEP. As with most "no tune-up" transmitters, a low swr is important. The 150 will perform up to specifications only if it is operated into an swr of 2:1 or better. At higher ratios, the transceiver protects itself by automatically reducing output power so that the final transistors do not overheat. For this reason, Swan recommends using an antenna tuner to keep the swr, as seen by the transceiver, as low as possible.

The 150 offers full break-in (QSK) on CW, something found on few rigs at any price these days. Break-in is accomplished by leaving the final amplifier always connected to the antenna through the low-pass filters. In the receive mode, the final power transistors are biased off, effectively creating an open circuit on the transmitter output transformer. The receiver input is coupled to the secondary of this transformer via a high-speed reed relay.

Perhaps the most unique technical feature of the Astro 150 is its method of frequency selection and tuning. This transceiver is one of a small handful of amateur HF rigs incorporating true digital frequency synthesis. Much of our 2-meter equipment (and even some CB gear) has used synthesizers for several years, but only recently has it become available in multiband HF radios.

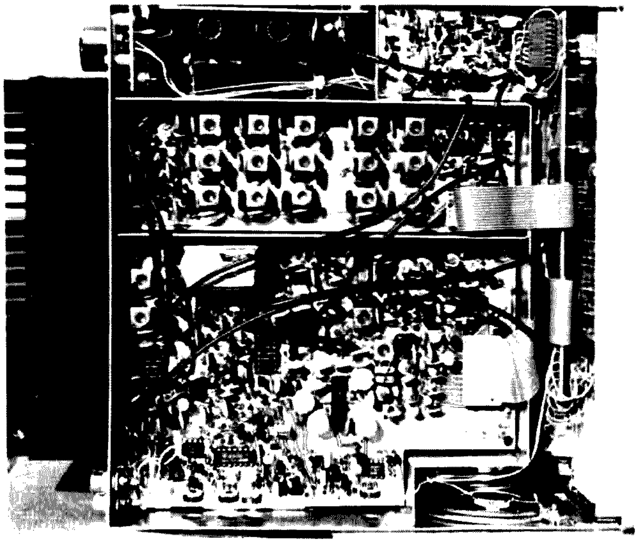
Incidentally, just because a transceiver has a digital display, this does not necessarily mean that it's synthesized. In many rigs, the operating frequency is determined by conventional vfo circuitry, and a frequency counter is used to produce the digital display. The principle of synthesized frequency control is completely different, as we shall see.

Swan's design uses a pair of phase-locked loops (PLLs) to provide precise crystal-controlled reference frequencies to six voltage-controlled oscillators (vco's). Five of these are designated as "band" vco's. The outputs from the band vco's are divided by a diode-programmed divider so that band vco frequencies are variable in steps of 500 kHz. The transceiver's bandswitch selects the proper vco and diode program for each band. The 7-32-MHz output of the selected band vco is summed with the 5-7-MHz output of the sixth or "tuning" vco to produce a local oscillator frequency in the 12-39-MHz range. The local oscillator is thus always about 9 MHz above the operating frequency, and indeed, the Astro 150 uses a 9.0165-MHz i-f.

Directing traffic inside the synthesizer is an 8048 microprocessor chip, a device from the same family as the popular 8080 chip found in thousands of microcomputer systems. A small amount of read-only memory stores a program containing the instructions which allow the 8048 to control this complex radio.

The microprocessor accepts as inputs the band and mode you have selected, along with signals from the tuning controls. It uses this data to produce signals which determine the frequency of the tuning vco. The 8048 also sends the proper information to the readout board to enable it to display the correct frequency. The microprocessor and its program also carry out other functions which would otherwise require much additional logic. For example, as long as power to the 150 is not interrupted, the microprocessor will remember the last frequency used on each band. If you want pileups on five different bands simultaneously, the Astro 150 can do it!

With this high-technology frequency-determining scheme, you wouldn't expect the 150 to



Top view of Astro 150 chassis.

have a conventional tuning knob . . . and it doesn't. The main tuning control is called the VRS (variable rate scanning) knob. The shaft of this knob is attached to a cam which actuates either of two microswitches, depending on which way the knob is turned. When actuated, these microswitches send signals to the 8048 microprocessor. For example, when the VRS knob is rotated clockwise from its neutral 12 o'clock position, the left-hand microswitch is tripped, sending a signal to the 8048, which then issues commands causing the transceiver to begin scanning upward in 100-Hz steps. If the VRS control is turned counterclockwise, the right-hand microswitch is tripped, and the transceiver begins tuning downward in frequency. A potentiometer attached to the VRS knob shaft determines the scanning rate. The further the knob is rotated from the neutral 12 o'clock position, the faster the frequency changes. Once the desired frequency is reached, the VRS knob is returned to the neutral position, and the scanning stops. Scanning control is also available via up/down push-buttons on the included hand-held microphone, making mobile operation safer and more convenient.

Other front-panel controls include both RIT and Fine Tuning. RIT changes only the received frequency (up to ±300 Hz), while the Fine Tuning control alters both transmit and receive

INTERNATIONAL 160 METER PHONE CONTEST

SPONSORS .... 73 Magazine, Peterborough, New Hampshire 03458.

DATES & TIMES .... 0000Z 19 January 1980 to 2400Z 20 January 1980.

OBJECT .... To work as many stations as possible on 160 meter phone in a maximum of 30 hours of allowable contest operation. Multi-operator stations may operate the full 48-hour period.

ENTRY CATEGORIES ... (1) Single operator, single transmitter, phone only; (2) Multi-operator, single transmitter, phone only.

EXCHANGE .... Stations within the continental 48 US states transmit RS report and US state; all others transmit RS report and DX country.

POINTS .... All contacts score FIVE (5) POINTS each. The same station can only be worked once for contest points.

MULTIPLIERS .... ONE (1) multiplier point is earned for each US state worked within the continental US; THREE (3) multiplier points are earned for each DX country worked outside the continental US.

FINAL SCORE .... Total QSO points times total multiplier points equals claimed score.

CONTEST ENTRIES ..... Each entry must include logsheets, dupe sheet for 100 or more contacts, a summary sheet, and a multiplier checklist.

ENTRY DEADLINE ..... All entries must be postmarked no later than 20 February 1980.

DX WINDOW .... All stations are expected to observe the DX window from 1.825-1.830 MHz as mutually agreed upon by top-band operators.

DISQUALIFICATIONS ... Contest disqualification may result if contestant omits any required entry forms upon submission of results; operates in excess of legal power limitations or frequency allocations within his given area; manipulates operating times to achieve a score advantage; or fails to omit duplicate contacts which would reduce the overall score more than 2 per cent.

AWARDS .... Contest awards will be issued in each operator category in each of the continental US states and DX countries.

CONTEST ADDRESS .... Those wishing contest information or entry forms or who desire to submit a contest entry should enclose an SASE and write to:

Dan Murphy WA2GZB
Post Office Box 195
Andover NJ 07821 USA

TOPS CW CONTEST
Starts: 1800 GMT December 1
Ends: 1800 GMT December 2

General call is "CQ QMF" and entry classes include single- or multi-operator. Use 3.5 to 3.6 MHz, USA Novices between 3.7 and 3.75; all contacts must be on 80 meters, CW only.

EXCHANGE:
RST and QSO number from 001.

SCORING:
Contacts with own country score 1 point. Each call area in A/K/N/W, VE/VO, VK, and UA, etc., counts as a separate country. Contacts with stations in the same continent are 2 points, other continents are 5 points. Contacts with HQ station, GW8WJ or GW6AQ, score 25 points. It is hoped to have a special station, perhaps GB2TAC, for another 25 points. Total score is total QSO points times number of prefixes worked (prefixes as per WPX award).

ENTRIES:
Send logs to: Peter Lumb G3IRM, 14 Linton Gardens, Bury Saint Edmunds, Suffolk IP33 2DZ, United Kingdom. Logs should be sent no later than January 31st. Contest results will be sent to all stations except eastern Europeans, which will be sent via the bureau. Due to postage costs, stations are asked to help by enclosing IRCs.

NORTH CAROLINA QSO PARTY
Starts: 1900 GMT December 1
Ends: 0100 GMT December 3

This contest is sponsored by the Alamance Amateur Radio Club. Suggested frequencies are plus/minus 10 kHz:

CW—3560, 7060, 14060, 21060, 28060.

Novice—3720, 7120, 21120, 28120.

SSB—3900, 7270, 14290, 28590.

EXCHANGE:
Out-of-state stations send RS(T) and state, province, or country. NC stations send RS(T) and NC county.

SCORING:
Out-of-state stations count 1 point per NC contact. The same station may be worked on different bands, modes, or in different NC counties. Multiply QSO points by number of different NC counties worked for final score. NC stations count 1 point per QSO and multiply by total number of states, provinces, or countries for final score. NC mobiles use the number of counties operated from for an additional multiplier.

ENTRIES AND AWARDS:
Your log must be signed; none will be returned. Logs must show RS(T)s, bands/modes, time (GMT), state, province, country, or NC county. On a separate sheet, please show name, call, and mailing address plus your total score and where operated from. In the case of multi-operator stations, this sheet must also list the call of the operators. Awards will be issued as usual. Logs must be postmarked no later than January 10th and sent to: Alamance ARC, Inc., 2822 Westchester Drive, Burlington NC 27215.

CONNECTICUT QSO PARTY
Starts: 2000 GMT December 1
Ends: 0200 GMT December 3
Rest period from 0500 to 1200 GMT December 2

The Candlewood ARCA invites all amateurs to participate in this year's contest. Phone and CW are the same contest. Stations may be worked once on each band and mode including OSCAR (and RS) as a separate mode. Novices will please identify themselves by ?n. W1QI, the club station, will operate CW on odd hours and SSB on even hours. Connecticut mobiles working in other than their home counties will receive special certificates provided they make at least 20 out-of-state QSOs. Mobiles count as a separate station in each county.

EXCHANGE:
Send QSO number, RS(T), ARRL section for out-of-state stations, and Connecticut county for Connecticut stations.

FREQUENCIES:
Suggested frequencies are 40 kHz up from the bottom of the CQ bands plus 3927, 7250, 14295, 21370, and 28540 for SSB. Watch for Novices on 3725, 7125, 21125, and 28125.

SCORING:
Each completed QSO counts 1 point, 2 points if with a Novice, and 3 points if via OSCAR. Also, contacts with W1QI count 5 points. Only one DX multiplier is allowed although all DX QSOs count for QSO points. Out-of-state stations multiply QSO points by the number of Connecticut counties worked (8 max.). Connecticut stations multiply the number of QSO points by the number of ARRL sections worked plus a maximum of 1 DX multiplier.

ENTRIES AND AWARDS:
Certificates for the top station in each ARRL section and each Connecticut county if the winner has at least 5 QSOs. Certificate to top-scoring station in each DX country. A Worked All Connecticut Counties certificate will be awarded to each station working all 8 counties during the contest. Logs must show all QSO info plus band, mode, and single- or multi-operator class. Entries must also show QSO points and claimed score. Enclose a large SASE for results. Logs must be postmarked no later than January 2nd and sent to: Skip Paulsen W1PV, 2 Ryders Lane, Danbury CT 06810.

Low-Cost Receiver for Satellite TV

—this modular design uses readily available technology

Author's Note: This article was originally presented by the author as part of the professional program, "Satellite TV and the Private User," at WESCON/79 in San Francisco CA on September 20, 1979. WESCON, the annual Western Electronics Show and Convention, is a large-scale trade show which features films, exhibits, and professional sessions related to all facets of the electronics industry.

The technological revolution which is making possible the distribution of television programming via satellite has been discussed in both popular and technical publications and at conferences and seminars.[1] In this article, I will explore the trade-offs involved in designing a wideband, tunable FM video receiver for processing and displaying DOMSAT (Domestic Communications Satellite) signals.

It should be recognized that there are at least as many conflicting receiver design philosophies as there are microwave engineers, and no claim is made that the concepts presented here are necessarily superior to any other approach. Nevertheless, this receiver does provide adequate performance at low cost, and the trade-offs encountered

mystique of microwave receiver design.

Signal Characteristics

Unlike the vestigial-sideband AM video standard used for terrestrial TV broadcast, DOMSAT video incorporates a wideband FM format, with audio multiplexed onto a subcarrier prior to modulating the composite. The resulting wideband channel (see Table 1) affords considerable "FM advantage" (signal-to-noise enhancement for a given carrier-to-noise ratio); however, the bandwidth and format tend to complicate the receiver design task.

Were a signal consisting

Video Carrier	
Channels	24

EIRP	+65 dBm

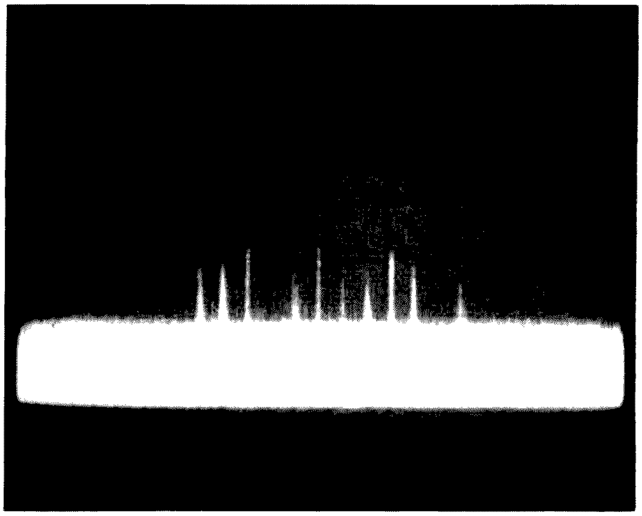

Fig. 1. Spectral display of a 4-GHz DOMSAT downlink recovered on a 4.7-meter antenna and amplified by a GaAs FET Low-Noise Amplifier (LNA). Horizontal deflection is 100 MHz/div, and vertical sensitivity is 10 dB/div. Eleven video carriers, along with their associated FM sidebands, are visible. Note that the fourth channel above the bottom of the band is vacant. Otherwise, channel spacing is 40 MHz and carrier-to-noise ratio appears to be on the order of 10 dB.

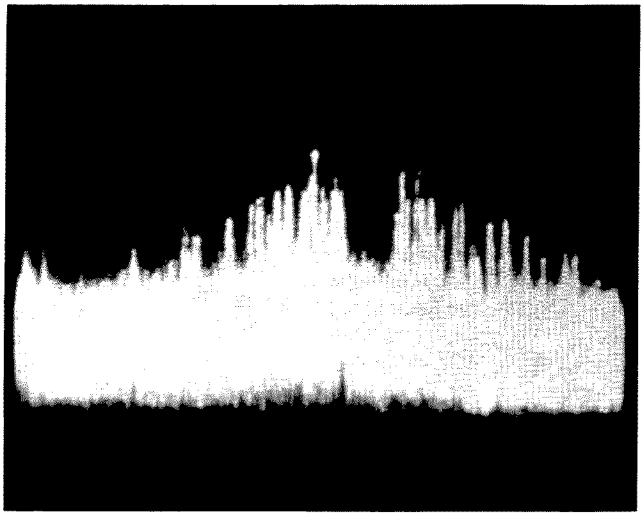

Fig. 2. Spectral display of a single wideband FM video channel after dual-downconversion to a 70-MHz second i-f. Horizontal deflection is 3 MHz/div. and vertical sensitivity is 10 dB/div. This is the composite FM signal from which video and audio are to be demodulated.

would involve merely heterodyning the selected channel in the 4-GHz transmission band against a stable microwave local oscillator (LO), and applying the VHF difference signal directly into the tuner of a conventional TV set. Unfortunately, with DOMSAT signals as they are currently formatted, such a downconversion process would merely spread unintelligible sidebands across six adjacent TV channels.[2] Thus, it becomes necessary to design a complete receiver, including heterodyne conversion stages, demodulators, and video and audio processing circuitry, to recover and display satellite TV.

Frequency Agility

It will be noted from Table 1 that the downlink band used by most North American DOMSATs is 500 MHz wide, and that for a given antenna polarization there will be present up to twelve video carriers, spaced 40 MHz apart (see Fig. 1). That these signals are of extremely low amplitude complicates the design of the Earth station's antenna[3] and low noise preamplifier,[4] but we will assume for the moment that an adequate signal-to-noise ratio exists at the input of the receiver to permit signal recovery. The problem at hand, then, is to select a particular 40-MHz wide channel from among 12 such signals in a 500-MHz wide band, while adequately attenuating the adjacent channels.

A Tuned Radio Frequency (TRF) approach, with detection occurring directly at the downlink frequency, would require readily-tunable bandpass filters of high Q (to accommodate the 1% or so channel bandwidth) and skirts steep enough to reject adjacent channels. Tuning requirements rule out both LC and resonant cavity filters, suggesting the use of Yttrium-Iron-Garnett (YIG) sphere resonators for channel selection.

Although YIG filters can readily be bias-tuned, their cost and the complexity of the required driving circuitry tend to rule them out for private terminal applications. Furthermore, it is far easier to tune a single oscillator than a bank of filters. This suggests heterodyne-downconverting a selected channel into a fixed intermediate frequency, at which demodulation may take place.

I-f Selection

The selection of intermediate frequencies for superheterodyne receivers involves careful attention to the required and realizable mixer bandwidths, image rejection criteria, demodulator circuit capabilities, and tuning constraints. These various considerations tend to be mutually exclusive, but it has been shown[5] that for narrowband systems, a reasonable compromise is achieved by selecting an intermediate frequency approximately one-tenth the frequency of the incoming signal. Although DOMSAT video hardly qualifies as a narrowband service, we can use the one-tenth rule of thumb to establish a starting point. For a 4-GHz input signal, this suggests a UHF i-f. However, the various demodulator circuits compatible with wideband FM video (quadrature detector, ratio detector, Foster-Seely discriminator, phase-locked loop and the like) are all most readily realized in the lower portion of the VHF spectrum. An obvious solution is to utilize dual downconversion, with first and second i-fs near 400 and 40 MHz, respectively.

In fact, numerous experimental DOMSAT video terminals have adopted the above frequency scheme, many employing UHF TV tuners for the second downconversion. The drawbacks to such an approach include the typical UHF tuner's restricted channel bandwidth, relatively high noise figure, and poor local oscillator stability. Nevertheless, when cost is the primary design constraint, these problems can be circumvented.

Not so readily resolved is the input filtering requirement which such a frequency scheme imposes. Assuming low-side first LO injection and top-channel reception, the first conver-

sion will generate an image frequency which falls a mere 300 MHz below the bottom edge of the downlink passband. An input filter capable of providing adequate passband flatness and minimal insertion loss over the 3.7- to 4.2-GHz band is unlikely to provide adequate image rejection if a 400-MHz first i-f is utilized. One may wish to raise the first i-f high enough to separate the image frequency band well away from the downlink passband, thus simplifying input filtering.

In fact, if the Low-Noise Amplifier (LNA) which precedes the receiver utilizes a waveguide input, then an image filter already exists. Rectangular waveguide is a high-pass transmission line. If low-side first LO injection is used and the first i-f is carefully selected, the LNA's waveguide input will itself reject the image frequency.

Most commercial LNAs utilize an EIA standard WR-229 waveguide input. This guide has a lower $TE_{1,0}$ cutoff frequency near 2.5 GHz. This cutoff frequency is about 1.2 GHz below the bottom edge of the receiver's required passband, so input losses will be minimal. But a first i-f of, say, 1.2 GHz, will place the image frequency as far *below* cutoff as the input passband is *above* cutoff. The image thus ends up quite far down the waveguide high-pass filter's skirts, and may effectively be ignored.

True, the fixed 1.2-GHz first i-f requires that the first LO be tunable, but we mentioned earlier that it's far easier to tune a single oscillator for channel selection than a bank of filters. And even at the top of the downlink passband, where the first LO must be tuned up to 3 GHz, the image at 1.8 GHz is sufficiently far below cutoff so that a 12-cm long input waveguide will afford on the order of 60 dB of image rejection.[6]

Another signpost pointing to the selection of 1.2 GHz as a first i-f is realizable amplifier Q. The 3-dB bandwidth of the i-f amplifier string must be greater than or equal to the 20-dB channel bandwidth in order to avoid unduly attenuating significant sidebands. Assuming a channel bandwidth of 40 MHz and an i-f of 1.2 GHz, this dictates an effective first i-f Q of 30. This value is readily realized with microstripline circuitry.

Despite the obvious economic advantages of the modified UHF TV tuner conversion scheme, it was decided to employ a 1.2-GHz first i-f in the Microcomm DOMSAT video receiver. But what of the second i-f—is it similarly constrained by the wide downlink passband? Actually not. With channel selection occurring in the first downconversion, the second i-f need only be wide enough to accommodate a single video channel. Downconverting the 1.2-GHz first i-f to any desired VHF frequency will allow ample second-conversion image rejection with simple i-f filtering while providing adequate bandwidth to pass the 40-MHz composite.

Since the communications industry has long utilized 70 MHz as a standard i-f for microwave links, it was decided to employ a 70-MHz second i-f in the DOMSAT video receiver. This makes it possible to utilize any of the readily available 70-MHz wideband FM i-f strips to demodulate the video information.

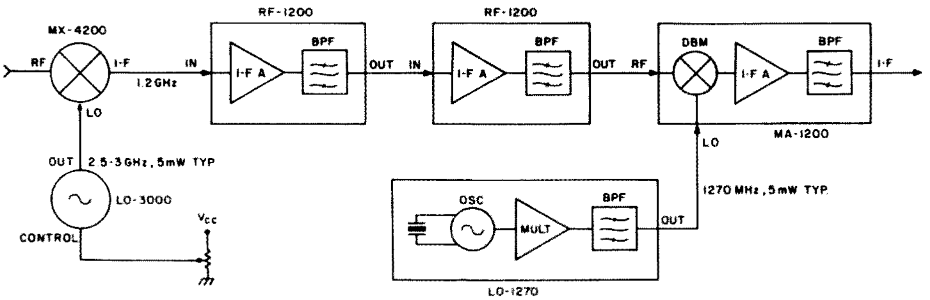

Fig. 3. Block diagram of the heterodyne downconversion portion of the DOMSAT video receiver. Shown at left is the 3.7- to 4.2-GHz input terminal from the LNA and feedline. The 70-MHz i-f output at right feeds the baseband demodulator and processing circuitry (see Fig. 7). The potentiometer shown at the lower left represents the resistive voltage divider which tunes the first LO for channel selection. Gain partitioning of the various blocks is discussed in the text.

Gain Distribution

Gain partitioning for the DOMSAT video receiver depends upon the available power from the satellite, the threshold sensitivity of the demodulator circuitry selected, and the gain of the receive antenna utilized. It has been shown that for the illumination contours typical of most North American DOMSATs, an optimum private-terminal antenna will exhibit on the order of +41-dBi gain.[7]

Given the EIRP and path loss numbers listed in Table 1, it appears that the signal level available to the LNA will be on the order of −90 dBm.

The input threshold for a typical phase-locked loop (PLL) integrated circuit operating as an FM demodulator at 70 MHz is on the order of −20 dBm. This suggests that between the antenna and the demodulator, roughly 70 dB of conversion gain is required.

There are three sources of gain available between the antenna and the PLL. These include the LNA and first and second i-f amplifiers. There are, similarly, three sources of loss in the system: the insertion loss of the transmission line which connects the LNA to the receiver, and the conversion loss of the first and second mixers. For a typical home installation, the feedline insertion loss may be on the order of 6 dB, and if double-balanced diode mixers are used for the two frequency conversions, it is safe to assume that the conversion loss of each will be on the order of 7 dB. This suggests that the overall gain of the LNA, first, and second i-f amplifiers will need to total 90 dB for adequate DOMSAT video reception.

In the interest of maximizing system stability and dynamic range, it is desirable to distribute the required 90 dB of gain uniformly between the rf and two i-f frequencies. A 30-dB gain LNA is clearly feasible at 4 GHz and would require three stages of GaAs FET amplification. This amount of LNA gain is sufficient to adequately mask the noise temperature contribution of the feedline and receiver, allowing the low-noise temperature of the FETs to predominate.[4] Similarly, it is practical to achieve the desired 30 dB of 1.2-GHz gain by cascading two stages of ion-implanted silicon bipolar transistor amplification. At 70 MHz, the required gain is readily available from thin-film wideband gain blocks produced by a number of different vendors.

A block diagram for the dual downconversion portion of the DOMSAT video receiver, partitioned in accordance with the foregoing discussion, is shown in Fig. 3.

Construction of Conversion Circuitry

During the initial system-development phase of any new product, it is common practice to build a number of different amplifier, mixer, filter, and oscillator circuits, each connectorized for coaxial input and output and with each circuit separately boxed and shielded. A modular developmental system provides the engineer with the flexibility of changing one or more circuits without having to disrupt the rest of the system. Microcomm's earlier efforts at modular receiver development have been documented previously.[8]

But modularization has advantages for a production system as well. If every function represented by a block in Fig. 3 is implemented in a separate, shielded module, then isolation between stages is maximized and the cross-talk and stability problems associated with stray rf coupling can be eliminated entirely. Further advantages are realized in the area of maintainability. Should a receiver fail, fault isolation by module sub-

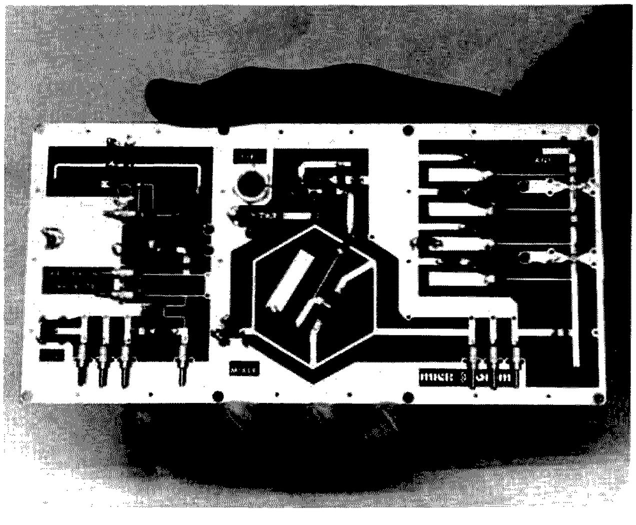

Fig. 4. Typical microstripline circuit module used for satellite video downconversion. Each module in the receive system is mounted in its own shielded enclosure, and all are interconnected via coaxial cable as discussed in the text.

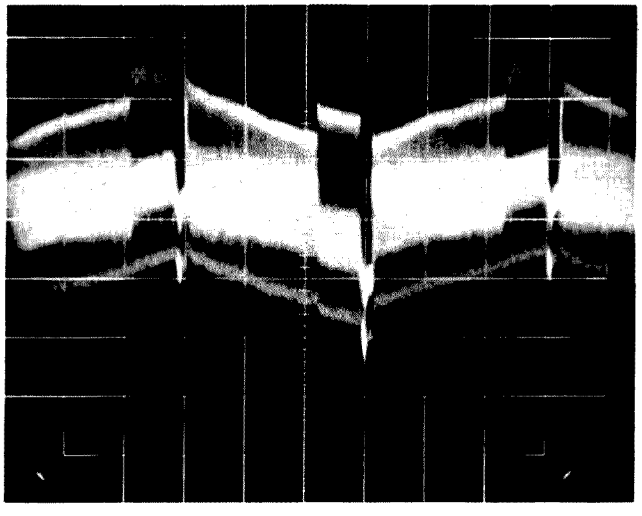

Fig. 5. Baseband output of the PLL demodulator. Presence of the energy dispersal waveform on the video composite is evident.

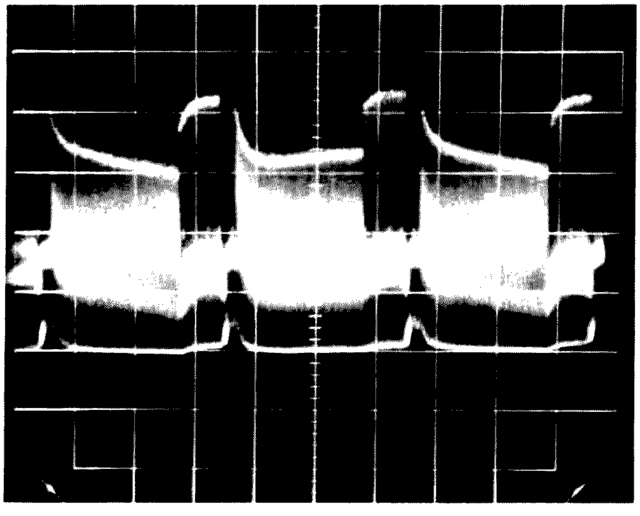

Fig. 6. The dc restorer is simply a diode clamp circuit which removes from the video waveform any vestiges of the energy dispersal waveform seen in Fig. 5.

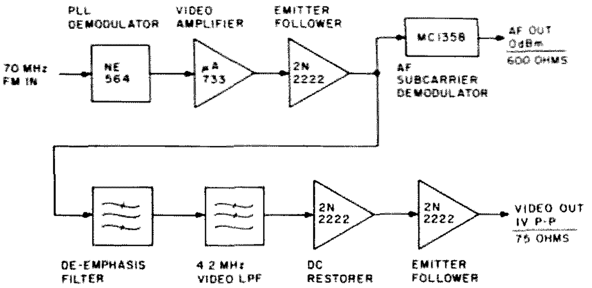

Fig. 7. Block diagram of the complete baseband processing portion of the DOMSAT video receiver. The above circuitry is driven by the output of the downconversion module set (see Fig. 3), and provides standard 1-volt video and 0-dBm audio outputs to an external modulator, studio monitor, or video tape deck.

stitution becomes a viable troubleshooting technique. And, of course, a modular system maximizes user flexibility by allowing customers to assemble from standard modules a custom system designed to meet their precise needs.

The specifications of the modules developed to implement Fig. 3 appear here as Table 2. Each of these modules employs microstripline construction, as shown in Fig. 4, to minimize component count and assure duplicability.[9]

Baseband Processing

Before the wideband FM composite shown in Fig. 2 can be displayed, several processing steps are necessary. The 70-MHz i-f signal will, of course, be demodulated first, and this may be accomplished readily by using a monolithic PLL in a standard circuit.[10] The output waveform from the PLL will contain both the video waveform and the modulated audio subcarrier, but superimposed on these will be found the 30-Hz triangular energy dispersal waveform added to all DOMSAT downlink signals as an interference reduction technique. This waveform is evident in the oscilloscope display in Fig. 5.

Prior to attempting to remove the energy dispersal waveform, it is desirable to amplify the rather feeble video level available from the PLL demodulator, and this may be accomplished using a single monolithic TV video-amplifier IC. Next, an emitter-follower permits splitting off the 6.8-MHz audio subcarrier for demodulation in a standard TV sound i-f microcircuit, whose associated circuitry is modified slightly for compatibility with the higher carrier frequency and peak deviation used on satellite audio.

After passing through a de-emphasis filter and passive video low-pass filter, the video waveform may finally be applied to a diode clamp circuit which will remove the energy dispersal waveform (see Fig. 6). An emitter-follower then establishes the desired 75-Ohm video output impedance to drive recording or display circuitry, as required.

A block diagram for a complete baseband processing subsystem is shown in Fig. 7. This circuit can be constructed on a single printed circuit board and incorporated into a complete DOMSAT video receiver by simply interfacing it to the downconversion circuitry shown in Fig. 3.

Fig. 8. The video output of the baseband unit, displayed on a TV set with the aid of the rf modulator in a video cassette recorder. Most DOMSAT viewers find the clarity and resolution of satellite video clearly superior to network video which is distributed by multiple terrestrial microwave hops.

Display Options

An ideal DOMSAT video receiver for the home Earth-station market would provide an intercarrier audio, vestigial sideband rf output for direct interface to the user's VHF TV receiver. Such an rf output may readily be realized by using any of the available video modulator microcircuits developed for the TV game and home computer industries. In fact, the video and audio levels available from the baseband unit shown here are entirely compatible with such modulators.

Unfortunately, incorporating an rf modulator in a commercial DOMSAT video receiver would subject the entire receiver to FCC type acceptance in the United States. As more than one home computer manufacturer has discovered, the type-acceptance procedure is burdensome in the extreme, with bureaucratic delays often precluding a timely market entry. In addition, the resolution and clarity of most of the available low-cost video modulators leave quite a bit to be desired, and rf modulation would tend to degrade overall video quality noticeably.

A possible solution would be to provide the user with simply a video and audio output from the DOMSAT receiver and allow him to display the receiver's output on a studio-quality TV monitor. However, few videophiles possess such a monitor, and the cost is prohibitive.

Fortunately, most videophiles do possess a videotape recorder (in fact, the owner of a home satellite Earth station would most likely find it impossible to function without one!) and the average video recorder contains an extremely high quality rf modulator. Allowing the user to interface his DOMSAT receiver to the TV via a video recorder provides an ideal solution to the type-acceptance dilemma. And those users who have no recorder are, of course, free to add an external rf modulator, any number of which are available in kit or assembled forms.

Equipment Availability

Once priced in the tens of thousands of dollars, DOMSAT video receivers are now being brought within the reach of the American consumer. The conversion modules shown in Fig. 3, for example, have, since late 1978, been available to the ex-

perimenter at $1000 complete, and to the OEM at significantly lower prices in production quantities.

It is expected that by the end of 1979, a complete, fully tunable DOMSAT video receiver, utilizing the above conversion modules and a baseband unit such as that blocked out in Fig. 7, will be available to the consumer for under $2000. This receiver will be fully packaged and assembled, including power supply, tuner, control circuitry, and inter-connecting cables. Such a receiver promises to make possible for the first time a complete, consumer-grade Earth station, including antenna and LNA, for under $4000. We can only begin to guess at the price breakthroughs which may follow! ■

A Simple 2m/10m Crossband Repeater System

—work the world with an HT!

Bob Heil K9EID
PO Box 26
Marissa Il 62257

With the rules relaxation concerning the crossband repeater operation and the clearance of the Technician license holder to be retransmitted on an HF frequency (tnx to the OSCAR program), we have a terrific opportunity to use HF links on our two-meter repeater systems with not too much effort and one heck of a lot of fun. A whole new world can be opened up to those who really haven't gotten a taste of the HF bands as well as those of us who are out just to experiment and enjoy all the benefits from such a hookup.

MARC Does It!

The Marissa Amateur Radio Club, Inc., in southwestern Illinois, has a three-site, two-meter repeater which has three receivers, a quarter-kW transmitter, 50 voice-ID tapes, a time machine, and an open autopatch and gives a good 100-mile coverage on two meters with rubber duckies! The idea was generated when I listened to Carlos TI2CF with his ten-meter auxiliary link. The interface to do this with WD9GOE/RPT was begun. A Pace 1000M CB SSB rig was converted to 10 meters with the American Crystal Company kit. This worked out fine and gave us a good little 15-Watt rig tied to a TA 33 antenna. Next, we needed to build a COR (carrier operated relay) that would be activated by the Pace squelch, to key the two-meter transmitter. At the same time, a spare keying line had to be pulled off the two-meter repeater COR so that when the two-meter signal was received, it would key up both the two-meter repeater transmitter and the ten-meter transmitter. Simple. Really! (See Fig. 1.)

Not a Ten-Meter Repeater

One point that should be noticed is that this system is not a ten-meter repeater. That is to say that the ten-meter signals received are *not* retransmitted on another ten-meter frequency. The ten-meter signals are repeated *only* on two meters at the same time that the normal two-meter signals are repeated on two meters, so, in actuality, we have a simple ten-meter auxiliary link between two-meter and ten-meter receivers and transmitters.

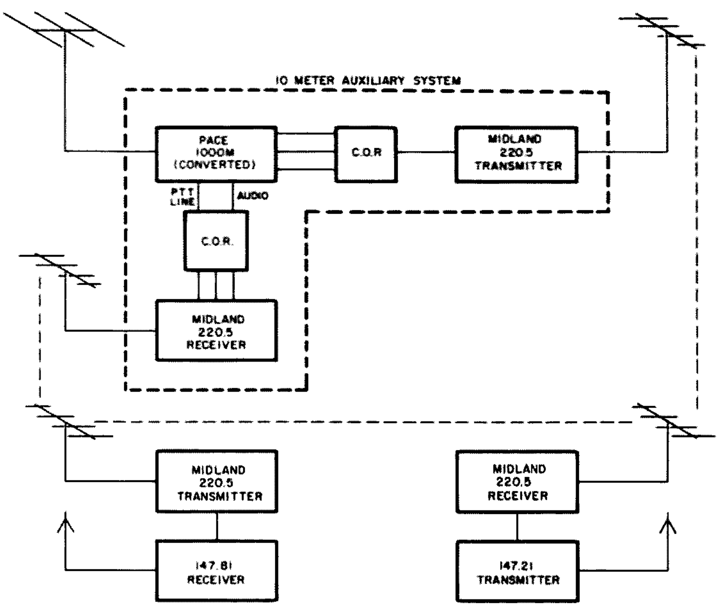

Fig. 1. Block diagram.

220 Link

The MARC group had a special problem that may not be relevant to most systems. This section may not really apply to your group, therefore, but it will show that this system is capable of a lot more, should your group want to carry it out further. The main receiver site for the 81/21 system is located 5 miles southwest of Marissa on a 250′ coal silo. The two-meter signals are relayed back to the 250-Watt transmitter, located in Marissa, over a 220-MHz link system using the Midland 13-509 equipment. The actual ten-meter link of WD9GOE/RPT is located at the home of K9EID. The

reason for this was twofold. The ten-meter system should be at the transmitter site, not at the receiver site, due to desense, etc., and the MARC group felt that very close tabs should be kept on the ten-meter link so that it was not abused. A Midland 13-509 transceiver was taken apart for link use, therefore (a great piece of gear for this service!), and used ahead of and behind the Pace 1000M so that all signals would pass from ten to 220 then to the two-meter repeater, and reverse. It sounds complicated, but it was very easy to do. Follow the block diagram and you can see how simple it really is.

If your group has a repeater system using cavities and duplexing, you can skip all the 220-link activities and wire the Pace straight through (see Fig. 4). One thought about the 220 link is that it also gives WD9GOE/RPT a 220-MHz link that 220 operators can get in and out of just as the ten meter operators are able to do, so we really got a lot of mileage from doing the extra link thing. It is not unusual to dial up the Marissa system and hear a QSO going on: one station operating on 147.81/21, another on 220.5, while another can be 1000 miles away talking to both of them on 29.590! That's communication! What is interesting is that some club members have only a 220 rig, some have only ten-meter equipment, and some have only two-meter equipment. All three of these can communicate very readily with no problem, and should you listen on any of the three frequencies, 99% of the time you would not be able to tell who was operating where or what mode they were operating. One thing that is interesting is that the SSB signals from ten meters come through the 220 and two-meter FM system, and you are hard-pressed to tell that that signal is not FM! Likewise on ten meters, it is *impossible* to detect that the SSB signal you are listening to is an actual FM signal except for one thing—the squelch tail! That sounds crazy on ten-meter SSB! (We recently modified the Motran receiver so that that blasted squelch tail is GONE!) The ten-meter link is no longer disturbed by the crashes!

Audio Coupling

The audio coupling has been done passively. An active limiter could be used here, but it was decided to try the passive route just for simplicity; so far, it has worked without any inherent problems. You perhaps will have to make minor adjustments of values to achieve linear audio response between the two outputs. Care also was taken at the audio inputs of both transmitters so that rf would not enter and cause undue problems. Bypass these audio leads with very small, .001 capacitors and, of course, use good shielded wire throughout.

COR Operation

The really good point about the Pace 1000M when used in this application is that it has a squelch circuit that works with the agc line and, therefore, will operate on SSB signals; this is something that most of the CB rigs will not do. Since the squelch does work on SSB signals, it makes it very simple to pull off a reference voltage, drive a simple COR, and use that to key up the two-meter transmitter. An interesting side effect of the Pace squelch is that since it does get activated via the agc line, a slight delay is noticed with the squelch, and that becomes our

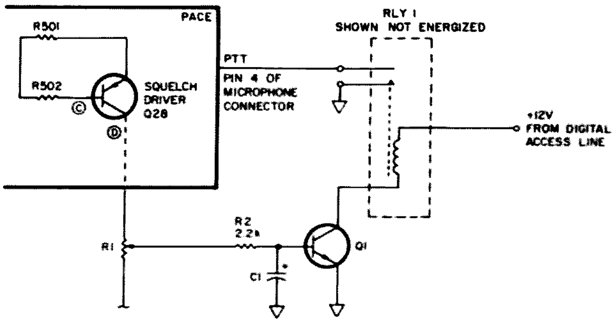

Fig. 2. COR for the ten-meter Pace.

2-second delay tail. It works well and was found to be adequate; delay circuits were not required to achieve the necessary hang time to allow things to switch over. (See Fig. 2.)

A worthwhile project for the two-meter repeater is a timer-reset beep. Without it, it is difficult for the two-meter operator to tell when the ten-meter signal dropped out (or turned the transmission over). With a reset timer "beep tone," the two-meter system is aware when the COR of the ten-meter receiver has been dropped. Because of the slight delay that the agc introduces, the timing is such that the COR does not drop out when the ten-meter SSB operator pauses for a breath between words. Pace certainly made things easy for us!

Choose Your Mode

As you can see quite easily, you can select the frequency and mode the ten-meter link will operate on simply by adjusting the Pace to those requirements. The MARC group at Marissa has chosen USB on 29.590. After spending much time and effort in checking with groups such as the 10-10 club, etc., 590 seemed out of everyone's way and has worked out well. The unit has, on occasion, been used on ten-meter AM further up the band. It would be an easy task to remote this procedure should you desire. With the great increase of CB conversion to ten-meter 29.6 FM, it might even work out for your group to use this mode if you have lots of ten-meter FM activity.

One of the interesting facets of the SSB mode is the absolute clarity when listening on two-meter FM. At first, one might ask, "How do you tune the ten-meter receiver?" The answer is that the repeater *never* is adjusted. It transceives (hopefully!) on the exact same frequency. The two-meter FM signals are patched to the Pace microphone input and are, of course, transmitted on ten-meter upper sideband. The ten-meter operator simply will tune in this USB signal as he normally would and, when it is his turn, merely transmits on the same frequency which the Pace receives and patches back through the two-meter FM transmitter. Easy.

CB-to-Ten Conversion

The first thing that you will have to do is get the Pace, or similar rig, working where you want it on ten meters. MARC used the American Crystal (American Crystal Supply, PO Box 638, W. Yarmouth MA 02673) conversion, and it

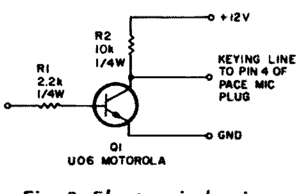

Fig. 3. Electronic keying.

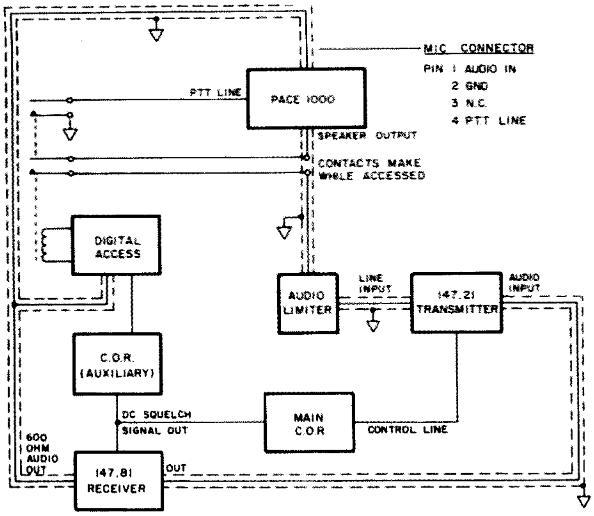

Fig. 4. Audio patching access control.

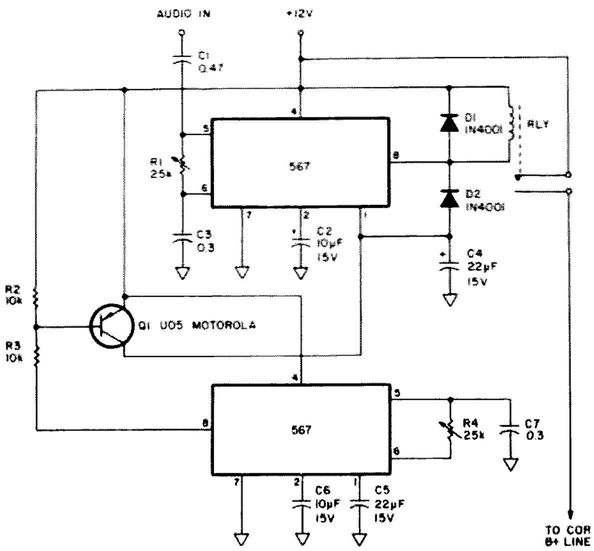

Fig. 5. Digital access.

took less than one hour to make the conversion and get the ten-meter rig on frequency.

A few modifications are available in the conversion kit that can be left out—mainly, the frequency expansion switches that allow a full one-megacycle coverage. By selecting the correct set of crystals in the kit, the Pace can be put on the frequency you have selected without the addition of the switches and cabling. American Crystal also recommends a modification that allows the "clarifier" to move the transmitter as well as the receiver. As long as you check the two frequencies very carefully and do not plan to move the ten-meter frequency, this modification also can be left out.

The COR pick-off point is taken from Q28. Fig. 2 shows the very simple, but very effective, COR circuit used to key up the two-meter transmitter. Spare contacts on this relay can be used for various other applications which may suit your particular needs. This one connection is the *only* connection that has to be made inside the Pace. Everything else is done from the speaker jack and microphone jack. Should you desire local audio from the Pace, you may want to install a switch (or wire the speaker jack permanently) to keep the speaker operational with a plug inserted into the speaker jack. Normally, the speaker wire is disconnected when a jack is plugged in. Since we will pull the ten-meter audio from this jack, you will not have any local speaker audio unless you make this change.

Two-Meter COR

The Pace will need only a ground to transmit for the PTT circuit, which will be tapped off at the microphone front-panel plug. If you do not have any spare contacts on your two-meter COR, parallel another relay across the main COR and away you go. You also could use electronic switching here to save you the problems of installing a separate relay. Look over this auxiliary circuit in Fig. 3. Fig. 4 shows the actual audio patching in and out of the two-meter repeater. It is very important to use good shielded cable with proper rf bypassing to keep the audio lines free of any stray rf that may occur when installing the additional equipment.

Access Equipment

Access to the ten-meter link can be accomplished in many ways. The simplest method is to use a telephone line with proper equipment to allow a control operator (or operators) to dial up the proper codes to complete the access link in the two COR circuits. (See Fig. 4.)

With digital circuitry today, it is very simple to come up with an easy access system for the ten-meter link. The only thing that the access equipment has to do is connect the 12-volt dc line to the COR circuits. With the 12 volts removed, power can be left on the Pace continuously, and even though there may be signals received on the ten-meter frequency, the COR will not bring up the two-meter system, or vice versa. By allowing the access equipment to connect the 12 volts to the COR, the ten-meter link then becomes active. Fig. 5 will give you a simple digital access to the system. We really don't need to go into great detail here because almost all of the repeater systems have some kind of access control for other functions and it should be easy to tie in the ten-meter access to this existing logic.

The only problem that your group may encounter, should you use ten-meter access, is that there is no really good foolproof access through ten meters. The MARC ten-meter group feels that the *only* access should be on two meters; a great many problems are eliminated while a tighter control can be kept on the system.

An Alternate Control System

Carlos TI2CF has an Icom 701 linked to a Spectrum two-meter repeater via a regular phone patch system, like the Data Signal RAP 200. This system controls the audio of the 701 just as it would the telephone line. To use this system, a member of the group accesses just as he would if it were a phone patch, only when this occurs, the ten-meter link will come up. When the two-meter station transmits, the patch circuitry keys the PTT line of the ten-meter transmitter. When the two-meter station listens, the ten-meter receiver audio is patched to the two-meter transmitter. The only problem with this system is that the two-meter transmitter would be keyed up con-

stantly (as it would when any patch logic is accessed). Should someone access the ten-meter link and *not* bring it down, the two-meter repeater stays on until someone brings it down. This system does allow the two-meter operator to switch the ten-meter link audio by simply pushing his or her mic PTT button. The ten-meter station received would not control any relays or controls. The system would work just like a phone patch but, of course, without the phone lines and actually substituting a ten-meter (or 20-, or 40-meter!) transceiver for the phone lines.

This system has some advantages but also needs additional equipment that groups may not have, nor could round up the finances to obtain. It also has some disadvantages for control, so your group will have to select the method that best suits its needs.

The Marissa system at WD9GOE/R has been in use since March, and many excellent contacts have been made by many members of the group as well as by dozens of interested newcomers that the system has attracted. It becomes very exciting to work Venezuela from southern Illinois on a Tempo S-1 HT with the rubber ducky! It is also very exciting to foreign stations when they discover what they are working! The system has brought the entire St. Louis area to its feet, and, again, attention to amateur radio is gained through simple technology, some imagination, and a few hours of hard work. This is only the beginning. Let's all get to work and see where we can go from here. It's all for amateur radio! ■

NOTE to 73 Subscribers

From time to time 73 Magazine makes its subscriber lists available to carefully-screened companies and organizations whose products, services or information may be of interest to you. In every case, we must approve all organizations wishing to mail to our subscribers. In every case they receive a list of names and addresses only—no other information we may have is divulged. Each organization may use the list only once and agrees never to make any personal or telephone solicitations from it.

The overwhelming majority of our subscribers appreciate this controlled use of our mailing lists—it helps them shop conveniently by mail for products and services they need, often at substantial savings. A few people prefer their names not be used. It is to them we address this message.

If you do *not* wish to be a part of this service, please complete the form below . . . your name will not be used in this manner for any reason.

(If you asked us in the past to remove your name from our lists, there is no need to repeat the request.) Please allow about six weeks for your request to take effect.

☐ I wish to have my name removed from the list of subscribers receiving mail other than the regular subscription to 73 Magazine.

Audio Booster for Mil-Surplus Receivers

—a must for headphone haters

One of my biggest pet peeves with military surplus radio equipment is the low audio output of some sets. And that is the one big problem with the R-648/ARR-41 radio receiver that I converted recently. (See "Another Surplus Treasure," *73 Magazine*, November, 1978.) This receiver worked fine with headphones, but not when the output transformer was changed for a speaker. If you have done much work at all with surplus radio equipment, you know what I am talking about!

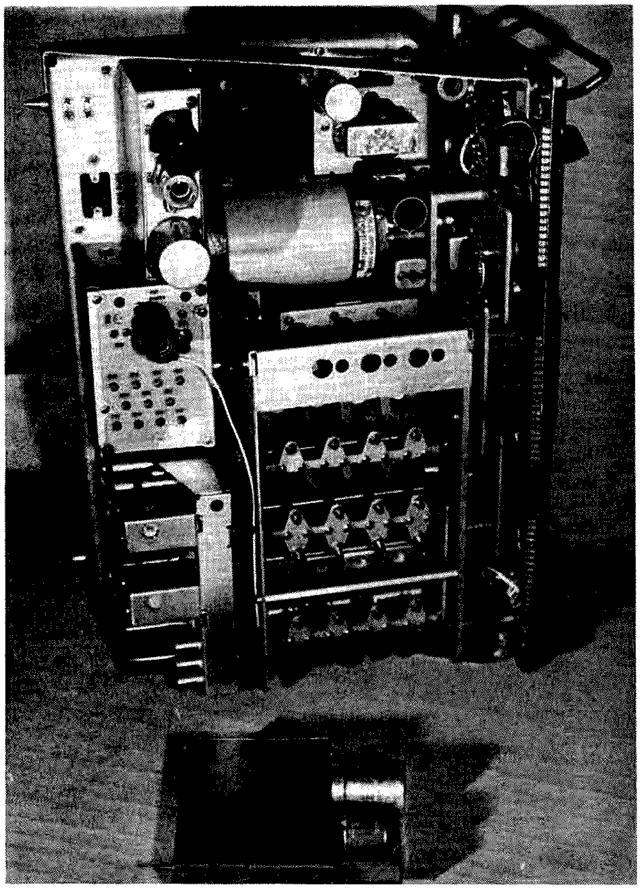

Photo A. Plug-in audio amp with rig.

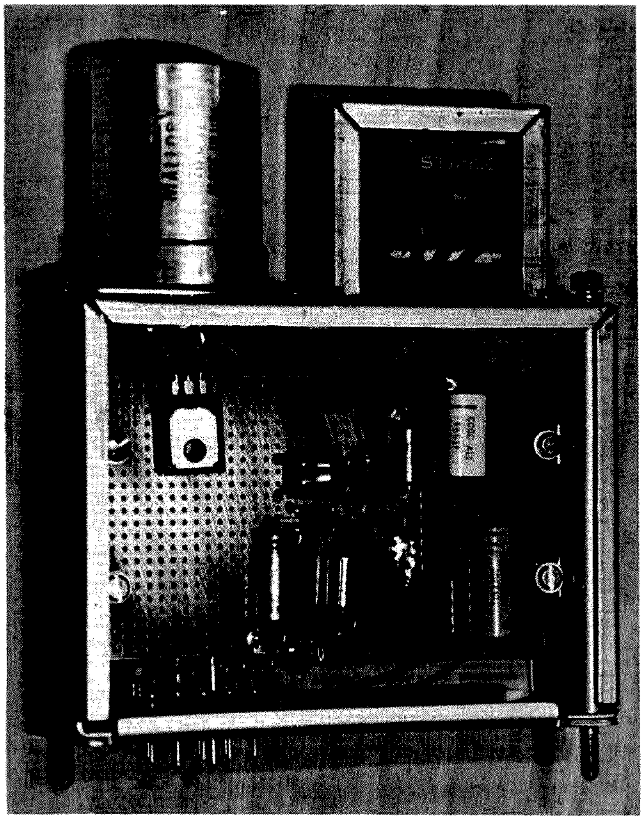

Photo B. Interior view of amplifier.

After studying the schematic of the audio stages, I saw that the best route would be to change the 5686 output tube to something heftier—like a 6AQ5. You could do it but for one

thing: Mounting the tube could create a height problem with the case. Also, you would upset the filament string in this series string set. So that was out.

The next best thing turned out to be a whole new audio amplifier, built from the ground up. This turned out to be a fairly easy job; an IC "building block" amplifier was pressed into service. It was possible to mount all parts in the module case, too, and the whole thing makes up a neat plug-in package. Oh yes, there is plenty of volume with a speaker now!

If you are working with other surplus sets and need an audio boost, this amplifier may do it for you. It is cheap to build, takes little room, produces little heat and creates a heck of a lot of volume. You are welcome to try it in your own unit; in this article, however, I will concentrate on the R-648 receiver conversion.

Before getting started with the actual wiring, let's take a look at what is being modified in the R-648. If you check out Fig. 1, you will see a simplified diagram of the receiver's audio section. Basically, you have two stages of gain (5814) and a stage of power (5686). The 5686 tube is the bottleneck here. The tube just won't draw enough plate current for any real power output, and is a poor choice for an audio output, especially since it sits there and draws 300 mA at 6.3 volts. It's a better heater-dropping resistor than output tube!

Note particularly the cathode connection of the first audio stage. Resistor R1305 is in series with the tube cathode and a pot on the front panel. This is the volume control. It is unique in that no audio signals pass down it, preventing hum pickup, yet making shielded cable from the volume control unnecessary. This is called a "dc volume control" and is used widely in IC-generation TV sets today. It is important to us because we are going to use it in our modification.

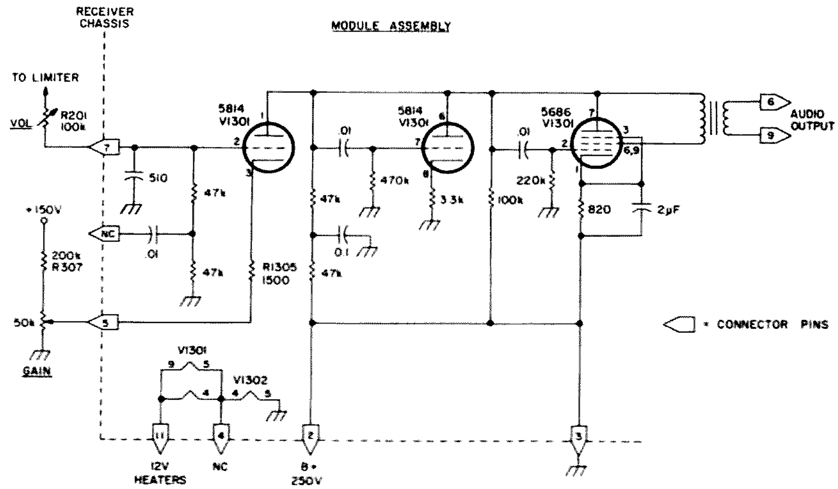

Fig. 1. Existing audio section of R-648.

The schematic shows what goes in place of the two tubes: two low-cost ICs. One IC you are probably familiar with—the National LM-380. This is the 2½-Watt power amplifier job. It is a natural for this job. The other one is a little less known, and that's too bad, because it is very useful. This IC is the Motorola MFC-6040 or Motorola HEPC6009. It is an electronic attenuator. It attenuates a signal when either a resistor to ground or voltage is applied to a control pin. There is no gain added, just attenuation. A simple 12-volt power supply rounds out the modification.

Construction is easy. I would suggest, however, that if your R-648 still has the tube filaments wired for 24 volts, leave the tube filaments in the audio module wired up. This will make sure that the other tubes get the proper voltages. One good advantage, besides the fact you eliminate several power resistors, is that the tubes can be bad. Just the filaments have to be good.

The photos and the schematic tell the construction story pretty well. I must add that I rewired the filaments in my receiver for 6.3 volts, so I was able to mount all parts in the schematic on the original module. This made a neat package. If you leave in the tubes, as required for the old 24-volt filament string, you will have to mount the power transformer elsewhere. I might add, at this point, that I tried a half-wave rectifier and filter directly from the 24-volt filament supply, but I had to supply a huge amount of filtering, and I had to drop the voltage to IC3 (voltage regulator) because it exceeded the chip's ratings. In the long run, a separate transformer for the audio amp power supply takes up less space, reduces construction frus-

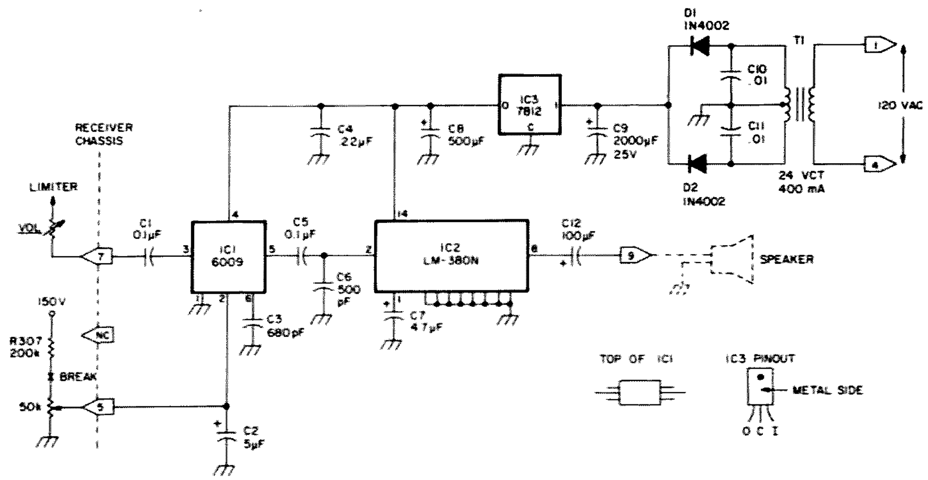

Fig. 2. Schematic diagram.

Parts List

C1, C5—0.1-uF disc or mylar® caps
C2, C7—4.7- or 5-uF, 16-volt electrolytic caps
C3—680-pF disc cap
C4—0.22-uF mylar cap
C6—500- or 470-pF disc cap
C8—500-uF, 16-volt electrolytic cap
C9—2000-uF, 25-volt electrolytic cap
C10, C11—0.01-uF disc caps
C12—100-uF, 16-volt electrolytic cap
D1, D2—1N4002 rectifier diodes
IC1—Motorola HEPC6009 or MFC-6040 attenuator IC
IC2—National LM380N power amp IC
IC3—7812 voltage regulator; 12 volts at 1 Amp
T1—24 volt c-t, 400-mA power transformer

tration, and possibly is cheaper.

I started construction by removing all components from the audio module, save the connector. Inside, I mounted a piece of copperclad "ground plane" perfboard, which serves as shielding and a heat sink for IC2. You don't have to duplicate this method of construction—copperclad perfboard is rather expensive—but at the least you must solder some kind of heat sink to the *grounded* leads of IC2. Two pieces of shim brass cut to size will do fine.

IC3 does not have to be heat-sinked, as its power dissipation is very low. You can see this IC in my unit mounted upside down under the filter capacitor.

The rest of the construction is noncritical and needs little comment. You might want to shield the input lead around C1 to the connector to cut hum pickup, though. In my unit, the 120 volts ac for T1 went to pins 1 and 4 of the connector. If you must leave the tubes in, you will have a wire connected to pin 4. This wire is not used inside the set, so cut it off inside the module and use pins 1 and 4 to carry the 12 volts from the added power supply to the audio circuitry. (Mount T1, IC3, etc., on the receiver chassis.)

After you have rewired the module, you will have to make a few additions on the main chassis. In my case, I ran 120 volts ac to pins 1 and 4 of the audio module chassis socket. If you kept the tubes in as ballast resistors, you will have to build the 12-volt power supply externally, and feed in the regulated voltage through the proper pins. After that is done, you must make one more change. Resistor R307 on the front panel must be disconnected or the attenuator IC will receive B+ through the *gain* control. This should be very easy. Unlatch the front panel and look at the rear section of the gain control. In my receiver, there was a yellow wire tied to the CW or far left-hand lug on the control. I cut it and I was home free.

After these modifications were complete, the receiver worked fine, and with room-filling volume! I haven't tried this modification on other surplus sets, but it should work if the proper power-supply voltages are available. And, oh yes! This conversion has other benefits, too. Besides a dramatic increase in volume, and less heat, the dc volume control can be switched and used as part of a squelch or noise blanker scheme. Or, how about a Selcal system? ■

Working with FETs

—part II: experiments with gain and supply voltage

In part I of this article, I began a discussion of audio amplifiers which use the FET, the transistor that thinks it's a tube. Let's continue by examining more of the functions these devices can be made to perform.

The triode FET small-signal voltage amplifiers are probably the all-time easiest circuits for a tube person to work with. This is one place where your tube-thinking will fit right in almost without change, and yet you will be working with solid state.

The circuits are straightforward, easy to duplicate, and the testing is nothing out of the ordinary. For basics, as with some of the other articles in this solid-state series, a microphone, audio signal generator, VOM, and scope are what you need.

It will help if you have a good junk box of small parts or a resistance sub box. Part of the fun on this one is watching what really happens when you play around with the values.

Here goes. Fig. 1 shows a basic triode tube voltage-amplifier stage. Notice that there is no cathode resistor. This stage would be a common first stage for a mike amplifier in an SSB rig. There are other uses for such a stage, too, but the important thing to note is the absence of the cathode resistor.

In theory, it looks as though the stage is running without any grid bias. There is a tiny smidgen, however; it is caused by "contact potential." The stage is able to get away with it because the input signal is assumed to be so small that the stage is still operating on a linear portion of its tube curve. The amplified signal is sent to the next stage, which is very similar but usually has the cathode resistor.

Our tube stage has a few other points about it. It is high impedance. (A tube is voltage-operated, that is, high impedance.) Notice that the grid resistor is 1 megohm. The load resistance of such a stage is often in the 100k to 220k range. A high signal output voltage is developed across the output resistance, but this is at very low power. The current may be on the order of a few mils or so.

Fig. 2 shows the same amplifier with an FET as the triode. This test circuit uses the Motorola HEP801. This is an "N" channel FET. That means it is roughly the same as the NPN bipolar transistor, as far as bias polarity goes. In fact, you hook up the voltage the same as for the tube; you just use less of it and only one supply.

The specs say a maximum of 20 volts between any of the elements. The maximum drain current is 15 mA. That's not much in the way of power, but it's not meant for power. While it can go to 20 volts at the drain, this series is geared to 12 volts, so we have some built-in safety margin.

There is one other mechanical oddity with the 801 which should be mentioned. There is a fourth pin which connects to the case. This is for shielding. For test use you can ignore it. If you want to be fancy, ground it or connect it to the source pin. You will do this anyway if you use it in an IC matrix board as I did.

Here's where the fun starts. Usually with solid state you have to fuss about the parts' values. This is the gizmo that thinks it's a tube. Let it think that. Use the same 1-meg resistor at the gate, since this is not critical at all. As with a tube circuit,

	R_G	R_S	R_L	C_S	V_S	V_{IN}	V_{OUT}	GAIN	Db
A	1M	NONE	2.2K	NONE	12VDC	1.5 P-P	6V P-P	4	12
B	1M	2.2K	15K	NONE	12 VDC	<1.5P-P	6V P-P	4.6	13.2
C	1M	2.2K	15K	10μF	12VDC	0.4 P-P	6V P-P	15	23.5
D	1M	2.2K	15K	10μF	20VDC	0.2 P-P	6V P-P	30	29.5

Table 1. Circuit performance test results.

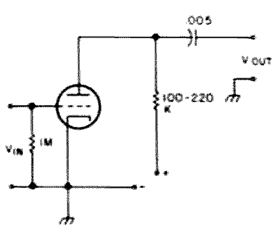

Fig. 1. Triode tube voltage amplifier stage.

250k on up would be common, and the circuit will work with much more and much less.

The next thing to fuss with is the drain load resistor. Use your substitution box and click your way down. With the mike input, at some point you will begin to get it to work. Then watch the scope and prune for best results. You might put your VOM in the drain circuit to watch the current; it's educational. The circuit should only draw a few mils. By the time you start to draw much current, you can see the performance fall off on the scope.

The drain resistance is not that critical, and a wide range of values wi]l work. This is a wide-range circuit. When it was tested above and below 12 volts, it worked from 5-20 volts. It might work at even less, although my supply would go down only to 5.

If you work at it, you may be able to get clipping with the mike, but here is a nice time to try adding an audio signal of some sort, and it would be nice if it was adjustable—or you can add a standard tube-type volume control as in Fig. 3. Just keep the input signal to less than 20 volts p-p.

I started with the theory that the operation would be quite similar to the tube version, but there was quite a surprise when I started comparing the data. With the simple circuit, your only variable is the load resistor. This gets adjusted for most output voltage. This may not be clipped. Once you get the most output, adjust the input signal until the output is undistorted. That will be your best value. Check a few resistance values on either side to make sure, though.

With my HEP801, this worked out to a 2.2k-Ohm

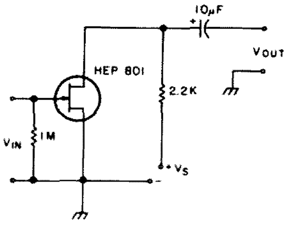

Fig. 2. FET triode circuit.

load resistance at a 12-volt source voltage. It gave a 6-volt p-p output. Then I added the source resistor. I had to go back and readjust the drain load. The values are not critical, but I settled on a source value of 2.2k and a drain value of 15k (Fig. 4).

This also got me an output of about 6 volts p-p. I had hoped for a clearer parallel to tube operation, but I don't really see it on the scope. With the tube, a cathode resistor would allow for more input voltage swing before distortion, but I really saw little difference between the two FET circuits. The scope values were about the same. The input distortion point was about the same, and I could get the same general output. So much for theory.

The oddest effect was when I added the bypass capacitor (Fig. 5). With a tube, this would have increased the bias and the output. It did increase the output to about 10 volts p-p, but it was clipped. All I could get was about 6 volts peak-to-peak from the circuit, but the resistor-capacitor circuit had more gain. What it did was lower the input distortion point. In other words, I could not have as high an input signal,

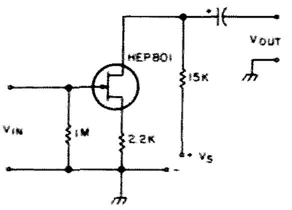

Fig. 4. Source resistor added.

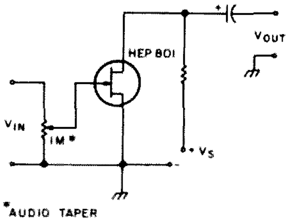

Fig. 3. FET volume-control circuit.

but the circuit would give me the same output with less input.

Rough scope measurements placed it at over 9 dB gain over the other two circuits. Thus, it is far more sensitive, but easier to overload. I used a 10-uF capacitor, but a higher value would be better, something from 20 to 100 uF.

The statistics of these circuits are somewhat alarming. They don't behave quite the way I would have expected. Table 1 shows a chart of various operating conditions. The first three have an operating voltage of 12 volts at the source; the last is 20 volts at the source. For this test, the input voltage was adjusted for an output of 6 volts peak-to-peak, and then the input voltage was measured p-p.

The output was divided by the input and the gain figured and converted into dB. In each case, the circuit was optimized for output in each configuration, with the circuit values shown being chosen. The no-resistor circuit would take a higher input, but needed a high input to get the 6 volts out. Its gain was

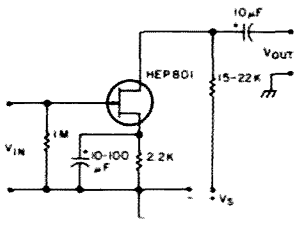

Fig. 5. Highest sensitivity and gain circuit.

only four.

The unbypassed resistor circuit was only slightly better. The bypassed resistor circuit not only had the best sensitivity to a weak signal, but also had much better gain. When the voltage was raised, the output voltage could have been more, but even holding to our present value, the actual gain of the circuit increased even at the lower levels. I was surprised at the difference in gain figures between the no-resistor and bypassed-resistor circuits. The other tests, such as for total output and distortion from overload, did not show up such a wide difference in actual circuit performance.

The low-gain high-input circuits would be the choice where you had gain to spare and needed high input capability. For most uses, you will probably want the bypassed circuit so you get some actual gain in signal and the ability to be sensitive. It was also unexpected that the gain of the circuit would increase with the increase in voltage to it. It was not just a matter of more possible output; the circuit worked better at the higher voltage when it was optimized for it. Still, I would have to recommend staying at the 12-volt or so level so as not to throw away your safety margin.

In actual fact, these circuits are not really optimum circuits as far as gain goes. They are useful when you want the FET capabilities, but other transistors can perform the gain function better.

These rough tests may not show the whole story. After all, it was a high-level input signal I was using, but these were intended to be rough-and-ready circuits to work with. There might be reason to use the source resistor even if the

capacitor was not required. This would not be the highest gain, but would be the most stable. Besides being the best as far as input overload, you also have the stabilizing effect of the extra resistor. It will prevent any problem with the drain circuit trying to draw too much current. It's unlikely, but it will give protection. It also may help stabilize the stage and even out operating variations as a tube does—but it just doesn't show on the scope.

I chose the 801 because it is commonly available. There are plenty of other audio FETs which should work with these circuits, and you may want to, or have to, prune values for best results. The same techniques will work with any FET. You should keep in mind that there is a built-in brick wall. After a certain point, you cannot have any more output voltage. In theory, you would run out of supply voltage to provide output, but you don't even get the full supply voltage swing, anyway. Past a certain point you are going to clip the peaks off because there is no additional voltage available to become output voltage swing.

The fact is, a lot of what you think ought to be available voltage just isn't there. Your output voltage swing is only what you have at the drain itself. These circuits are centered on 12-volt source voltage. That's at the power input, not what's at the FET drain. Even though the current is slight, the voltage measured at the drain terminal was just about 5.5 volts dc. That's all you are going to get as output voltage swing; even though the source may be more, it's what's at the FET that counts.

This brings up an interesting question. If that's all the voltage there is at the FET and all the voltage available for output swing, why not increase the source voltage?

Good question. When it was done, setting it to 20, the circuit worked even better, but the FET drain voltage was still only about 12 volts, which means an output voltage swing of even less than that.

What about increasing the source voltage until the drain voltage as measured reaches 20 volts, the maximum allowable?

Here, you face several design decisions. As a practical matter, if you wanted to try it, you would start with this circuit and increase the source voltage while measuring the drain voltage and current. When it reached the desired value, you would probably want to go back and try some different values at the load resistor. You would have to get a new best value for the higher voltage. This would mean some resetting of the resistor and the voltage, back and forth. You would arrive at the best values for your 20-volt drain voltage, though, if you use the method described here. It is likely that you would get increased performance, too, but there are drawbacks.

The first is the higher source voltage. You would need somewhere around forty volts. This series was geared to 12, since most equipment these days wants to use batteries if possible.

It also might be mentioned that my supply goes up only to 20 volts. This test would have been outside of the given specifications for the articles. There also is the matter of safety. Since the 20-volt maximum would be met by the higher source voltage, what effect would this have when you really started pushing out a 20-volt peak-to-peak audio signal? You would be running close to the ratings, which is not the best way to design.

Still, if the test setup is available and you are willing to risk a bargain FET or so, go ahead and try it. The basic monitoring procedure should tell you what is going on, and the test will give you an even more complete picture of the full capability of the FET. As to applying it in a circuit, that would depend on how you were going to power the final circuit.

Trouble with small-voltage amplifiers accounts for a great deal of the distortion problem in equipment. Input overload is common. Depending upon the type of amplifier, it may be biased to accept a certain input level and start to clip a peak because the bias is wrong for a higher level. That's why you find some circuits designed to handle a high-level input, even though it is intended for a lower-level use.

Musical instrument amps often have that feature. A guitar might work fine, but one with a built-in preamp would distort if the amplifier input circuit couldn't handle it. After that, it's a question of your output voltage swing. You may have lots of gain, but how much can you use before you get up to all the output voltage you can have and start clipping?

If you are looking for distortion, you can see these effects with your scope in a circuit. If you are building, you can build to take care of some of them.

Still, without even trying, we have opened the door to further developments of this simple circuit. They are easy to implement and have their own place in practical usage. We'll discuss them in part III of this article. ■

Build this $50 Mini-Counter

—three-IC design goes to 135 MHz

Sooner or later, anyone who does much work with communications equipment discovers the need for an accurate frequency counter. Let's face it, crowded communications channels make knowing your frequency more important than ever. This is where this counter project comes in.

Would you like to have a counter that measures frequency up to 135 MHz and beyond—one that is pocket-portable with battery power to make accurate measurements simple anywhere? Of course you would! The Model 304 Communications Counter has these features and much, much more: a low price tag of about $50, easy, one- or two-evening construction, and a superior sensitivity from 4-mV rms at 27 MHz to 12-mV rms at 135 MHz with input protection.

The 304's battery drain is low enough (130 mA) that you get long hours of operation on a set of charged nicads. You get a frequency range of below 1 MHz to over 135 MHz, covering ham, CB, commercial, radio control, and TV frequencies. And, best of all, you can measure the frequency to within 100 Hertz of what the transmitter is putting out. If you are in a hurry, you can select a reading to within 1 kHz, and get five readings per second versus one reading per 2 seconds on the 100 Hz range. Accuracy can be up to ± 0.002% ±1 count if the counter is calibrated on a frequency standard. Now that you know what this counter can do, go out and look at units selling from twice to three times as much as this one. One wonders why no one has thought of this design before.

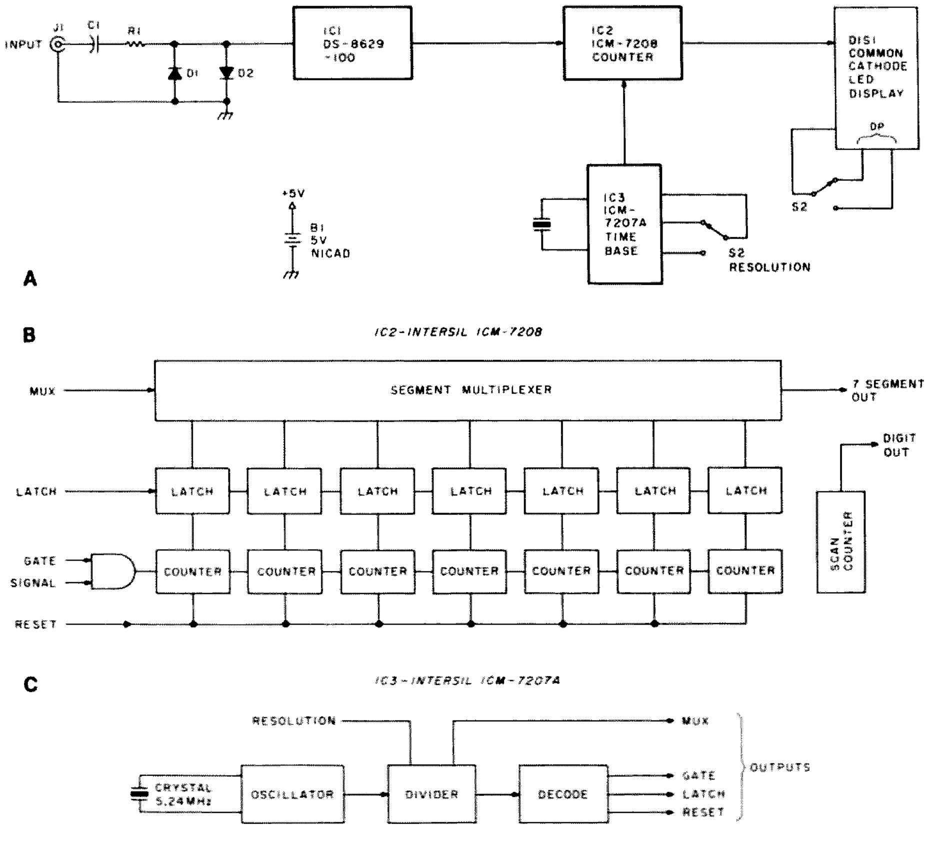

Fig. 1. (a) Block diagram of the model 304 counter. It features a 6-digit display, a 135-MHz counting range, and only three ICs. Power is supplied by a 5-volt nicad battery pack. Switch S2 selects either 1-kHz or 100-Hz resolution of the input signal. (b) Inside the ICM-7208 (IC2) counter array. (c) Inside the ICM-7207A timebase controller. An input connected to the divider section controls the gate time, and thus the resolution of the signal being counted by IC2.

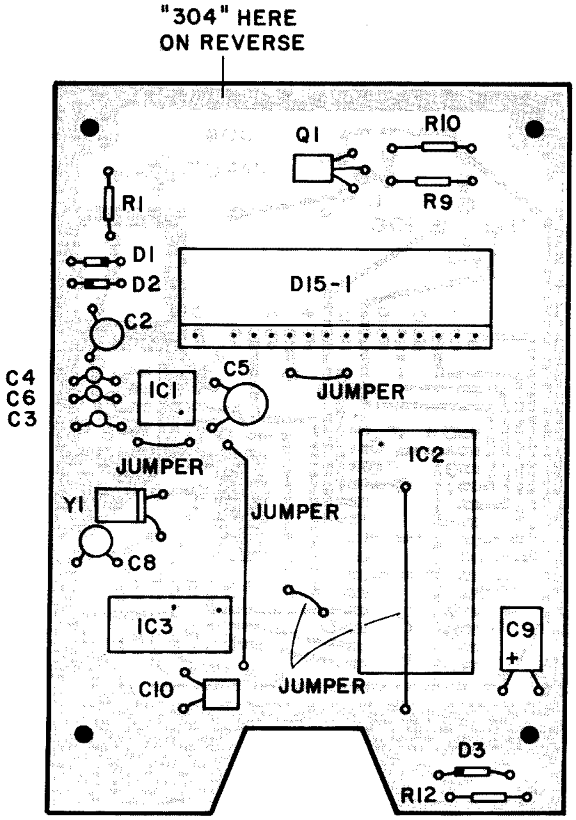
Construction of this project will be a pleasant surprise because it is very

Fig. 2. Component side of the board. Be sure to get all jumpers installed before the sockets go in.



easy. Thanks to a clever PC board layout, this project uses only a single-sided PC board, making duplication from the pages of this magazine a snap. There are only six wire jumpers in the board—for those of you who hate to install jumpers. There are sockets for all ICs and a minimum number of components. Since there are only three ICs and one transistor, your construction time for the board should be about four hours of casual work. Add another evening for the cabinet work and you are all set.

The parts in this counter should be easy to get. The two main CMOS chips have been on the market for nearly three years, and the prescaler chip has been used for well over one year. The rest of the parts are not too critical. All parts are available from the surplus houses. To assist you, however, I am including addresses of typical suppliers of the key parts, plus the addresses of the manufacturers who make the ICs. If necessary, you can write for a local dealer's name and address.

How It Works

This counter project is based on three ICs: One amplifies and divides the signal by 100, another counts it up and displays 7 digits of information, and the third generates precise timing signals to control the second chip. Check Fig. 1 for details as you read.

Input signals applied to J1 first encounter a protection network composed of C1 (which blocks dc), R1 (which limits input current) and D1-D2 (which limits input signal). The purpose of this network is to protect the counter from "real world" overloads such as an accidental dose of excessive dc voltage, 120 volts ac, and excessive rf signal. This keeps IC1, the preamp/prescaler chip, safe.

Next, the protected signal goes to IC1. Although this IC was designed by National Semiconductor for synthesized FM stereo radios, it works great in a counter. It has a preamp stage for high gain which has sensitivity of up to 4 mV at 27 MHz, then a series of ECL (Emitter Coupled Logic) and low-power Schottky TTL dividers. It divides the input signal by 100, so 100 MHz in equals 1 MHz out. This is necessary because the counter-display chip to be described won't count a TTL signal much beyond 2 MHz.

The divided signal enters IC2, a CMOS/LSI chip that counts it and displays the results on an LED display. Fig. 1 shows a general overview of this chip. The signal from IC1 passes through seven decade counters. They count up the signal. After it is counted, the data is passed on to the display via the latches (one per decade counter), through the multiplexing circuitry, and on to the display. Actually, the multiplexing circuitry consists of a big data selector at the output of the latches, squeezing 7 digits (at least 4 lines each) into a single set of 7-segment lines. The latches hold the signal while the decade counters are reset to zero and count up the signal again. The latches are then opened allowing the new reading to pass through to the display. This prevents the rapidly changing decade-counter outputs from reaching the display and causing a blur of numbers. The sequence in which the count-latch-dis-

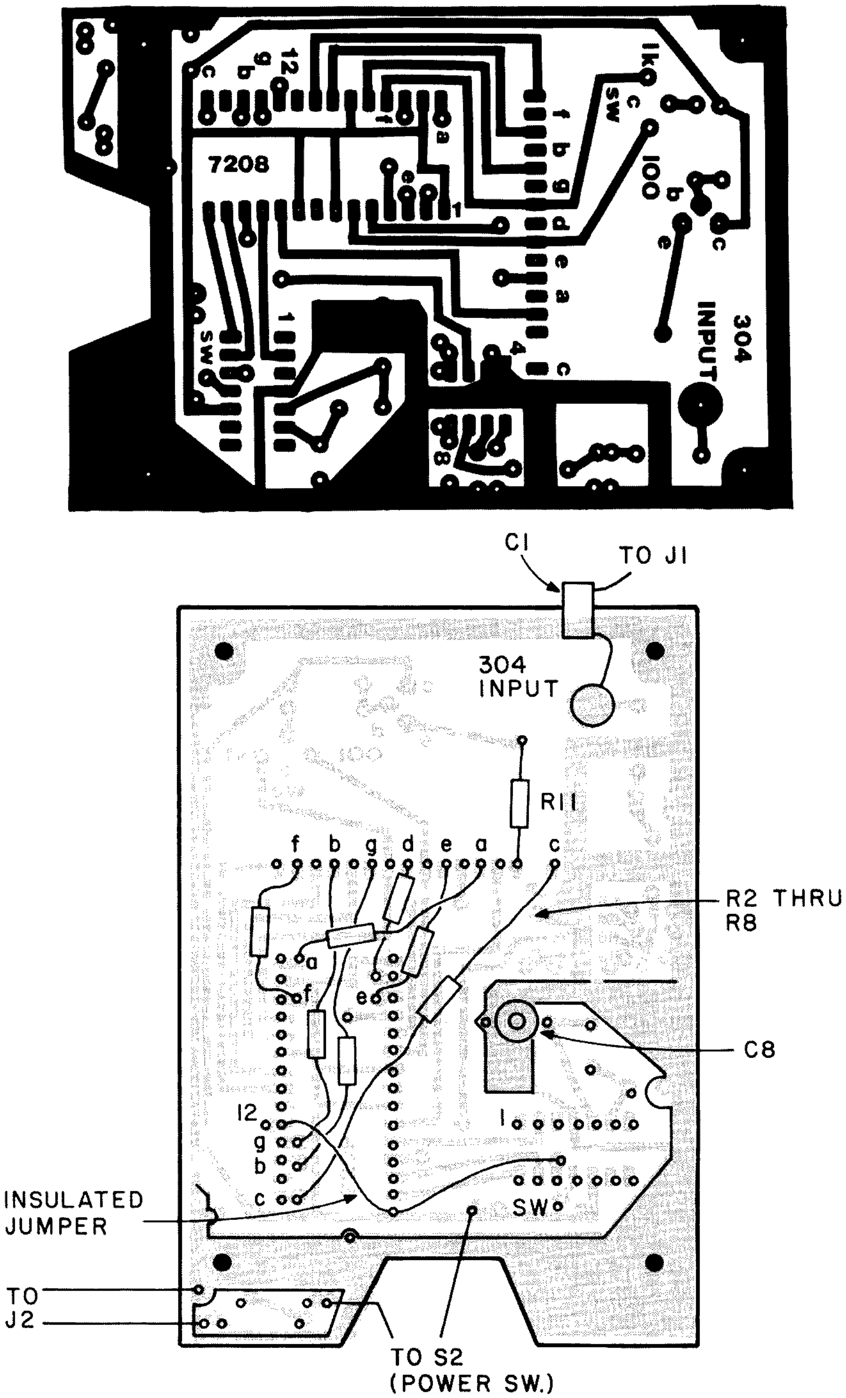


Fig. 3. Foil side of the board. Take your time and install those resistors correctly!

play-reset cycles occur is determined by the third IC.

The third IC generates the key signals necessary for IC2 to count the input signal properly. Fig. 1 shows a block diagram of this chip. A 5.24-MHz crystal connected to IC3 is the source of the proper frequency. It drives a Pierce-type oscillator inside the chip, which has the advantage of very high stability. (The circuit isn't much like the old 6AG7 tube Pierce oscillators of days gone by, but it accomplishes the same result.) The output drives a divider chain composed mostly of binary devices, and then the output drives a series of gates generating the precisely-timed gate, latch, and reset pulses needed by IC2. Also, an input connected to the divider chain controls its length—or number of stages—and selects a 1-second gate time or a 100-ms gate time. An output from IC3's divider chain also carries the multiplex signal for IC2. This signal determines when a digit will be scanned by IC2's multiplexer, and is just as important as the other signals.

Construction Guide

The first step is to round up the parts. If you are lucky, you can probably scrounge most of them from your junk box, but more likely you will have to buy at least the ICs. All of them have been available to the industry for nearly three years, and they are starting to pop up in the ads.

The LED display is commonly used in low-cost calculators, and can be almost any such unit; the pinouts have been pretty much standardized by various manufacturers. We have used National NSB-188, Litronix DL-94 displays, and others with success. The HP unit specified is recommended because of its superior appearance, but its $12 price tag may drive you to scrounging a junk calculator instead. Order any parts you need, plus the crystal. If my own experience is any indicator, you should order the crystal first. They are custom made, and take time to get.

The next step is to obtain or make the PC board. Luckily, this one is a single-sided type, and can be made at home using the G-C "Lift It" kit, or the newer printed circuit transfer films such as PCP type A, which is carried by Tri-Tek, Inc. (See distributor list for address.) It might be wise to silver-plate the finished board to improve high frequency performance, but that is up to you. While the improvement will be slight, the appearance will be considerably better. Drill all holes with a number 64 drill, and then drill out the four corner holes with a 1/8" drill. Now let's start the wiring.

You should install the jumpers and IC sockets before doing anything else. Refer to Fig. 2, which shows

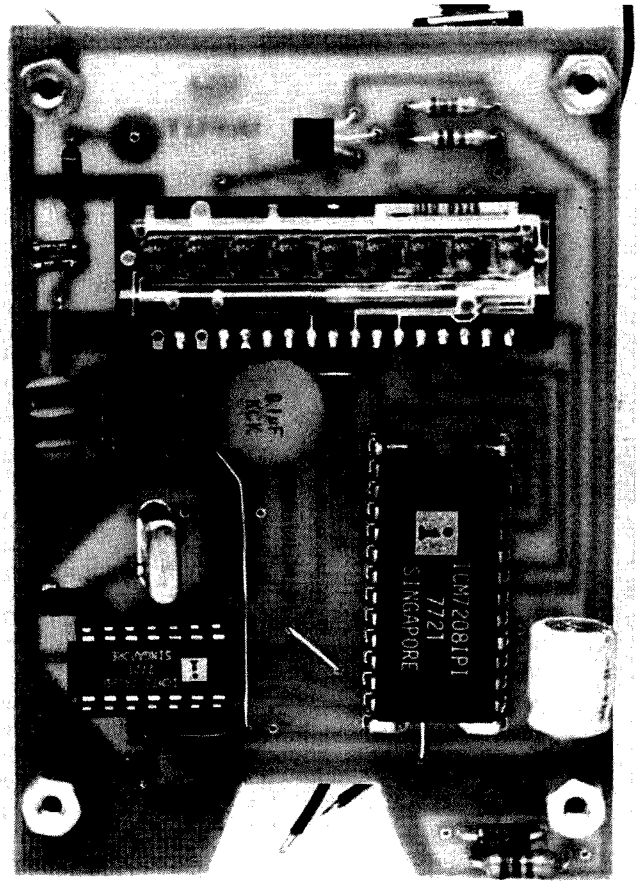

Fig. 4. Completed component side of the circuit board. Your finished board will look like this.

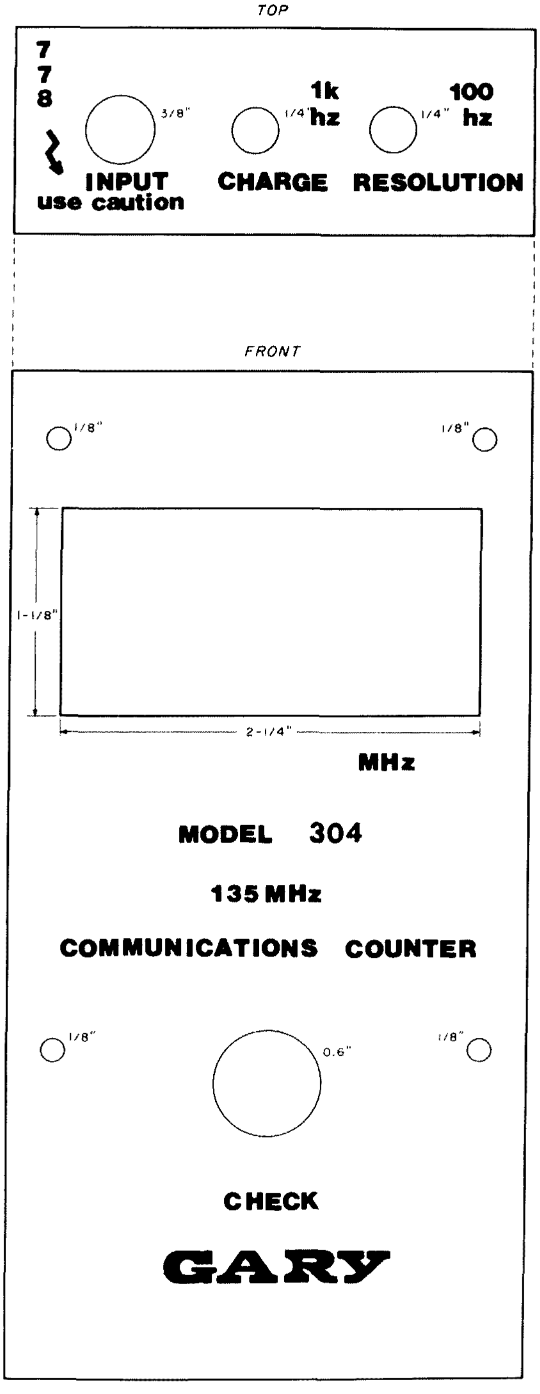

Fig. 5. Cabinet drilling template.

the component side of the board. Cut up three 1" pieces of no. 28 solid wire or resistor leads. Then cut two 2" pieces of wire. Install one 2" wire between the two holes near the right center of the board, as shown in Fig. 2. Install the other 2" jumper between the two holes near the left center of the board. Install a 1" jumper near the bottom of the board at the cutout. Move up to the center of the board, and install the remaining two 1" jumpers. Be sure to get the jumper nearest the left center of the board in the proper holes. An 8-pin IC installs next to it. When done, check to be sure all connections are soldered. Also, trim away the PC board at the bottom to form the trapezoid-shaped cutout, if you haven't already done so.

Next, install the 8-pin low-profile IC socket in the top left corner, next to that small jumper. Move down from it and install a 14-pin low-profile socket near the bottom edge. Finally, install the 28-pin socket next to the right edge of the board. I recommend the use of low profile sockets because they make later installation in the cabinet easier. Molex® pins will suffice, however. Check for solder bridges, fix, and flip the board over. Cut a 1¾" piece of insulated hookup wire, strip, and solder one end to pin 12 on the 14-pin socket, and the other end to pin 19 on the 28-pin socket. This wire shows up on Fig. 3. (Note that there is a "1" to identify pin 1 on each socket.)

The next step is to install the eight segment resistors on the foil side of the board. About ¼" of each resistor lead appears on the other side of the board for mounting the display, so don't trim the leads off from the row of wires in the center of the board. Start with the A segment resistor, R2. Lay the resistor against the board between the A on the socket (28-pin) and the A pad in the center of the board. Pass the resistor end through the A pad, so that the lead comes through the hole in the center of the board. Remember that this is for the display, so don't trim it. Solder to the pad. Bend the resistor body so that the other lead won't touch any other foil but the A pad on the 28-pin socket.

This process is identical for the other resistors, and

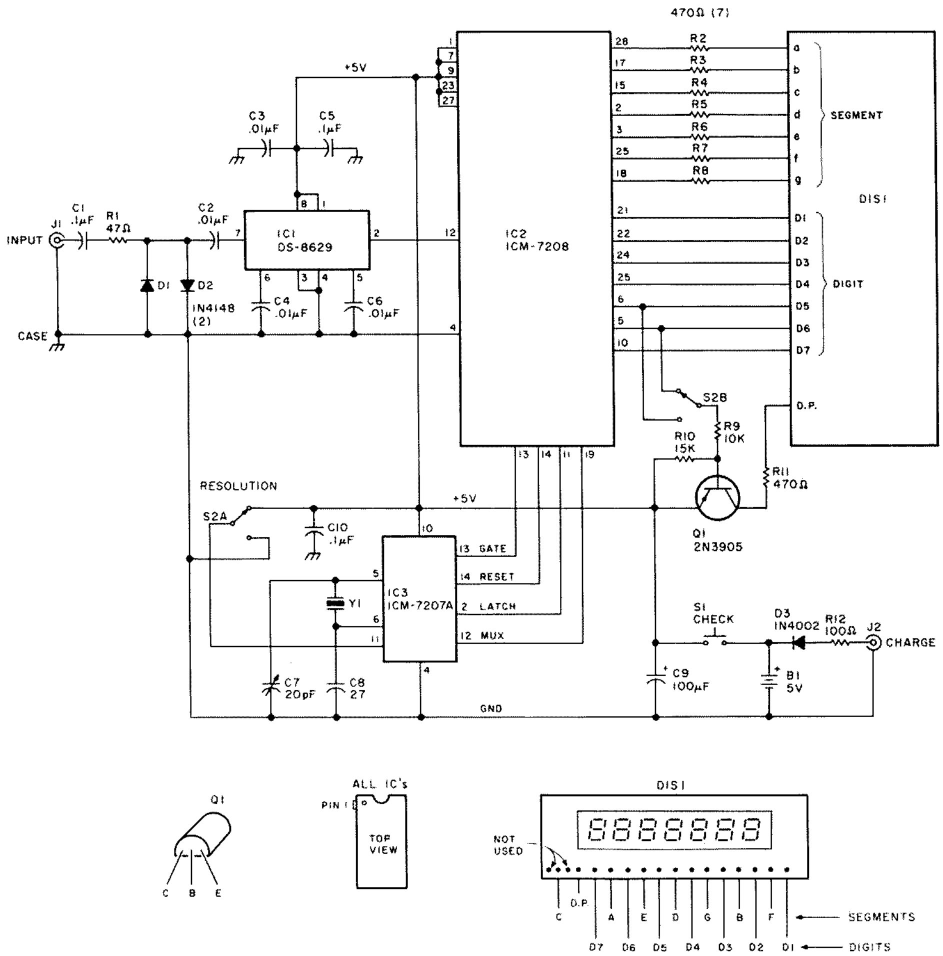

Fig. 6. Schematic diagram of the complete model 304 counter. All parts except the batteries and jacks and switch mount directly on a PC board.

is shown in Fig. 3. Repeat with installation of the D segment resistor. Position it over the A resistor you just installed, and bend the leads so they go from the D in the center of the board to pin 2 on the big IC socket. Note that there isn't a D next to pin 2 on the 28-pin socket. (There wasn't room for it.) Continue by installing the E segment resistor in the same manner, leaving at least ¼" of lead sticking through the center of the board to mount the display. Continue with the F, G, B, and one end of the C resistors. Attach a piece of bare wire to the other end of the C resistor, slip a piece of insulating tubing over it, and solder the wire to the C pad on the big IC socket. Pick up another 470-Ohm resistor and bend the leads so that one end goes to the pad just below "Input" on the board, and to the display. Cut the end flush with the board where the lead comes through near "Input," but not the one coming through the center of the board. That concludes the resistor installation for the display.

Continue by cutting up seven 1" wires for use as jumpers. These jumpers tie the digit leads from IC2 to the cathodes on the display. Heavy wire, just large enough to fit the display holes, might work better here, but the wire size you use is up to you. Bend one end of each wire into a small right angle, so that the wire looks like the letter L. Pass a wire through the foil side of the board, and place the short arm against the foil pad. Solder carefully. Put a wire in each pad that doesn't have a resistor. Use patience and care to prevent the wires from touching the adjacent resistored pads. This concludes the hardest part of the project.

Turn the board over to the component side and very carefully clip the 15 wires down to about ¼" above the board. Place the display over the wires, being sure to leave the hole on the the far *left* side of the display open. All holes on the *right* side must be used. Do not leave a hole open here or the counter won't read right. Press the display down flush against the board, and solder quickly. Use a minimum of heat to avoid loosening the wires soldered to the counter PC board. Clip off the excess wire.

The rest of the wiring needs no comment; refer to Fig. 4 for details. Install resistors R9 and R10 at the top of the board and R1 along the left side. Move to the bottom right and install R12. Now you have installed all resistors.

The semiconductors go in next. Install Q1 at the top center of the board, as shown in Fig. 4. For your convenience, the E, B, and C were marked on the reverse side of the board. Move over to the top left side of the board and install D1/D2 in the spaces near R1. Note that the bands on these diodes point in opposite directions. Move to the bottom right corner of the board, and install D3. That completes the semiconductor installation. The IC installation will follow later.

Now let's install the capacitors on the front of the board. Refer to Fig. 4, then turn to the top left side of the board. Install C2-C3-C4-C6 as close as possible to the board. Jump over the 8-pin socket and install C5 as close as possible to the board. Bend it flush with the board before soldering. Move down the left side next to the 14-pin socket and install C8 near it. Then jump over the socket and install C10 as shown. Bend it flush with the board before soldering. Skip over to the bottom right side of the board and install C9. Be sure the negative terminal faces the outside edge of the board. That completes capacitor installation on the front of the board.

While you are working with the front, dig out Y1 and install it next to C8. Also, bend the crystal over against the board edge before soldering. The photo shows it standing up, but this is not normal practice.

Flip the board over to the foil side so that you can install the remaining ca-

pacitors. Install C1, standing on end, at the input pad. Leave the other end free. Install C7 in the spot near the center of the board. Note that on most trimmers there are three leads. The two closest together go to the heavy ground foil on this counter, while the third goes to the crystal and IC3. That completes capacitor installation.

Next, the switch and mounting hardware are installed. Attach six 3" wires to the terminals of S2. Then wire up this switch as shown in the schematic and Fig. 4, cutting the wires to size as you go along. Install four spacers in the corners with 4-40 hardware and lockwashers. Note that the spacers are on the front side.

That just about wraps things up on the module. Finish by installing the ICs. Be careful about pin 1 orientation. Remember, pin 1 is identified on the PC board if you get confused. Then cut two 1" pieces of hookup wire, strip both ends, and install at the bottom of the board near the cutout. See Fig. 3. Also, cut a 5" piece of the same wire and attach near the end in the bottom left corner of the board. That completes the module assembly. It can be tested by applying 5-volts dc to the wire off the bottom center of the board.

Now you get to work the case. Fig. 5 shows a drilling template for the front of the box. Drill out the box and nibble the display hole. Clean up the box, label it with press-on transfers, and spray it with clear acrylic spray to preserve the finish.

Complete the assembly by installing the module in the box and wiring it up. First, install J1 and J2 in the top of the box. Then slip the module into the box and secure it to the front with screws and lockwashers. Mount S2 on the top of the box, too. Snap in S1 and wire it up. Install the battery pack and wire it up to the other side of S2 and ground. Finish up the job by wiring up J2 and C1 to J1. Don't close up the box until you finish calibration. Charge up the batteries and you are all set!

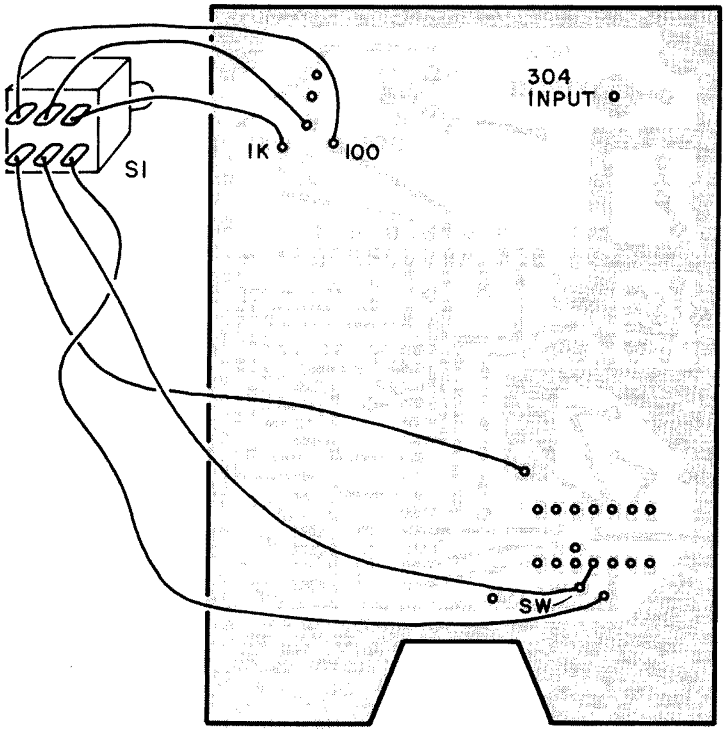

Fig. 7. Rear view of PC board showing switch wiring.

Calibration and Operation

There are several ways to calibrate your counter, with the simplest being to measure a known frequency. This is how I calibrated the model 304 counter. Connect a signal of 50 mV or so at 10 MHz from a fre-

Supplier List

Note on the "Factory" column: These people should be contacted *only* for a local distributor; only JAN Crystals will sell small quantities of parts to individual users.

quency standard to J1. Your standard should be accurate to at least ± 0.001%; ±0.0005% or better would be highly desirable. Press the check button and set the resolution switch to 100 Hz. You will get a reading close to 10 MHz. Adjust trimmer C7 until you get a reading of exactly 10.000 MHz. That completes calibration with a standard. If you don't have access to a frequency standard, a transmitter will do as well. You should have a high-quality counter to measure the transmitter. A CB set will do. Attach a piece of coathanger wire about 12″ long to J1. Then key the transmitter after you set the resolution switch to the 100-Hz position. Key the transmitter in brief steps and do not modulate it. A walkie-talkie is ideal for this since little power is necessary. Adjust C7 until the counter reads the exact transmitter frequency when the counter is held near the antenna. That completes calibration of the counter. Close up the counter case and secure it with screws.

Operation is a snap with this counter. Simply connect low-level signals to be measured to J1 and press S1. You then read the frequency off the display. The resolution switch, S2, is designed to offer you two time bases, and, thus, two different gate times. Use the 0.1-second position where you want a speedy display of frequency, and use the 1-second position where you want greater accuracy. This will allow you to read up to the last 1 kHz position on the display with S2 set to 0.1 second, and read to the last 100 Hz position with S2 set to 1 second. As you can see, each has advantages.

A few tips on using this counter: You might want to fabricate a 12″ whip antenna out of a male BNC connector and a piece of coathanger wire. Epoxy the wire inside the plug. With this setup, you should be able to measure a 100-mW CB walkie-talkie at least 15 feet away. If you performance-select IC1, this counter will cover the 2 meter ham band. Finally, whenever you measure a transmitter or signal generator, be sure to operate it in the unmodulated mode, or SSB units in the CW mode. This will give you maximum accuracy in your measurements. ■

Model 304 Counter Specifications

1. Accuracy: Adjustable to up to ±0.0002% or better, short term. Also ±1 count error on all measurements.
2. Frequency Range: From below 1 MHz to over 135 MHz.
3. Gate Times: Switched 1 second or 0.1 second. Display correspondingly updated 2 seconds or 0.2 seconds respectively.
4. Input: About 500 Ohms at low signal levels (below 0.5 volt).
5. Power requirements: 5 V dc at 130 mA, no signal. Power supplied by nicad batteries.
6. Resolution: 100 Hz and 1 kHz of the measured frequency.
7. Sensitivity: Typical rms sine wave sensitivity for stable count is 55 mV at 1 MHz, 4 mV at 27 MHz, 5 mV at 50 MHz and 12 mV at 135 MHz.
8. Special Features: Hand-held portable unit. Diode-protected input, easy construction, long battery life, etc.
9. Display: 0.105″ LED calculator-type with 7 digits.

PC Boards

The PC board (stock #STGM-279) for this project is available for $5.60 (drilled) or $4.00 (undrilled) from O. C. Stafford Electronic Development, 427 South Benbow Rd., Greensboro NC 27401. Add $1.00 for shipping.

Parts List

B1—4 "AA" Nicad batteries in square holder
C1—0.1-uF, 200-volt Mylar capacitor
C2, C3, C4, C6—0.01-uF, 50-volt disc capacitors
C5, C10—0.1-uF, 25-volt disc capacitors
C7—6-to-20-pF trimmer
C8—27-pF mica capacitor
C9—100-uF, 6.3-volt electrolytic
D1, D2—1N4148 diodes
D3—1N4002 rectifier diode
IC1—National DS-8629N VHF prescaler
IC2—Intersil ICM-7208IPI counter chip*
IC3—Intersil ICM-7207AIPD timebase controller chip*
J1—BNC connector, UG-1094, Amphenol 31-221
J2—RCA jack
Q1—2N3905 PNP silicon transistor

Resistors: All resistors ¼-Watt film except for R12.

R1—47-Ohm resistor
R2 through R8, R11—470-Ohm resistors
R9—10k resistor
R10—15k resistor
R12—100-Ohm, ½-Watt resistor
S1—SPST Push-button switch
S2—DPDT miniature toggle switch
DIS-1—Hewlett-Packard 5082-7441 9-digit LED display, "Industry Standard" calculator LED display, Poly Paks 92CU2954, or similar.
Y1—5.24288 MHz crystal in HC-18/U holder with wire leads. Loading capacitance is 12 pF, accuracy is ±0.005% at room temperature.
Misc.—9-volt ac/dc battery charger with RCA plug, PC board, Bezel, 3/8″ spacers (4 each), LMB CR-531 case, 4-40 screws, wire, etc.

*Available from Poly Paks as a set. Stock #92CU4079.

A Versatile, Variable Active Filter

—dc switching and 8-pole response make this one a winner on RTTY or CW

Eric J. Grabowski WA8HEB
30312 Arnold Road
Willowick OH 44094

Recently, my interest in RTTY operation was rekindled. The thought of using the existing tube-type terminal unit, however, was not a pleasant one. A rework of the terminal unit seemed appropriate.

A good place to start was replacing the bulky LC filters with active filters. Although many active filter circuits have been described in previous articles, none was exactly what I needed. Consequently, the circuit presented here was developed. The application is not limited to RTTY; with some value changes it can be used for CW reception or other uses where it is desired to pass a single frequency while rejecting all others.

Design Goals

After some initial brainstorming, the following list of objectives was prepared:

1. Ultimate selectivity should be less than 100 Hertz, but some intermediate choices should be available.
2. Minimize power consumption. Single supply operation. Operation consistent over a wide range of supply voltage.
3. Some type of dc-switching technique should be used for selectivity selection to simplify wiring and provide for future control by microprocessor.
4. Capability to bypass the filter altogether.

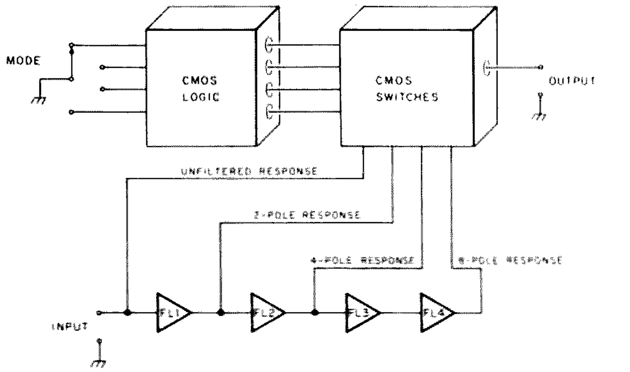

Fig. 1. Block diagram illustrating the concept of dc switching. Wires to the remote mounted switch carry dc levels only. Stray currents induced into these wires will not degrade the filter performance.

Center Frequency	R1—R4	R5—R8	R9—R12	Comment
2975 Hz	220k	430k	6.8k	RTTY Space (850 Hz shift)
2295 Hz	270k	560k	9.1k	RTTY Space (170 Hz shift)
2125 Hz	300k	620k	10k	RTTY Mark
750 Hz	820k	1.8 Meg	27k	CW

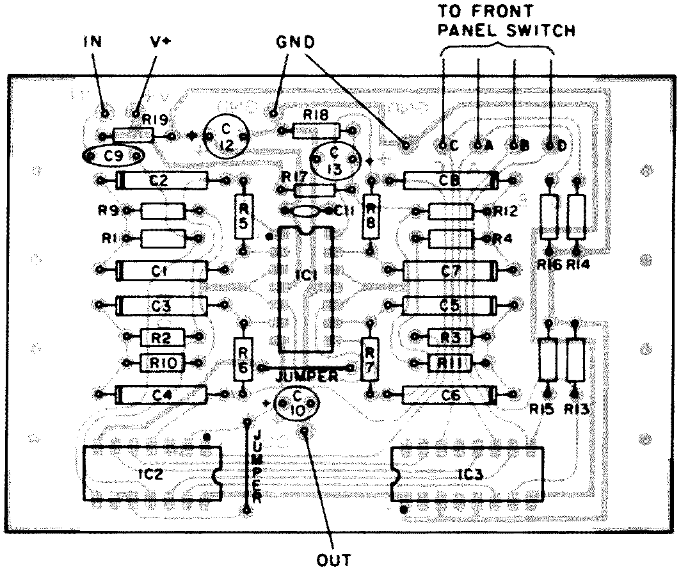

Fig. 3. Component placement drawing. A dot is placed near pin 1 of all integrated circuits for identification.

Filter Circuit

The LM324 quad operational amplifier was selected for the filter circuit. Each of the op amps is configured as a two-pole active filter and cascaded in a daisy chain fashion. Each stage has a Q of about 4, unity ac gain, and a center frequency determined by the R and C values chosen. The outputs of all op amps except the third are applied to the switching circuitry. The decision not to use the third output was arrived at experimentally, and experience has proved this to be a wise choice.

Table 1 identifies the values of resistors used for the RTTY mark and space frequencies. Values are also shown for a CW filter centered at about 750 Hertz. (C1 – C8 = 0.001uF)

For best results, the frequency-determining capacitors should be a high-stability type. Cornell-Dubilier series WMF is a good choice, and they are readily available.

If you want to use the filter on some other frequency, the R and C values will have to be calculated from formulas. Since there are more standard resistor values than capacitor values to choose from, it is usually more convenient to arbitrarily select a capacitor value and then use the nearest standard value resistors.

Dc Switching Circuit

Two complementary MOS integrated circuits comprise the dc switching circuit. A CD4049 hex inverter is used to drive the control inputs of the CD4016 quad analog switch.

A pull-up resistor normally holds each hex inverter input at the positive supply voltage. This forces the inverter output and the associated control input to ground potential. As long as the control input is grounded, the switch appears open. A four-position rotary switch is used to select which switch is closed by grounding the appropriate pull-up resistor.

Since there are only four switches in the IC package, and the unfiltered input uses one of them, one of the filter outputs had to be sacrificed. The output of the third filter seemed to be the least useful; consequently, it was deleted

Construction

The circuit was built on a printed circuit board 3-5/8 by 2-1/2 inches from the artwork shown. For those of you unable to roll your own, arrangements have

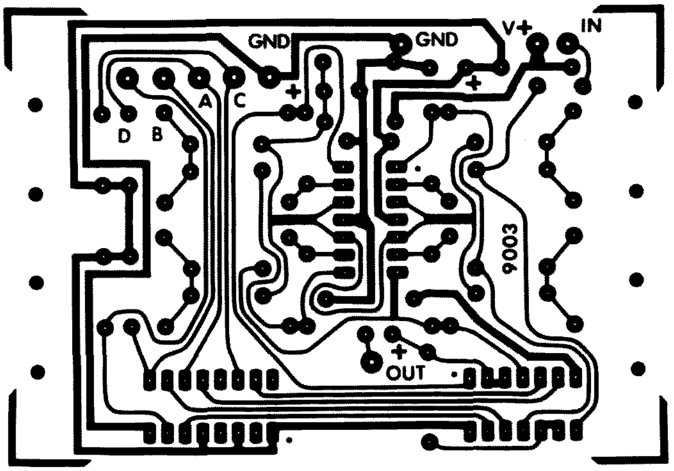

Fig. 4. Actual size artwork of the foil side of the printed circuit board.

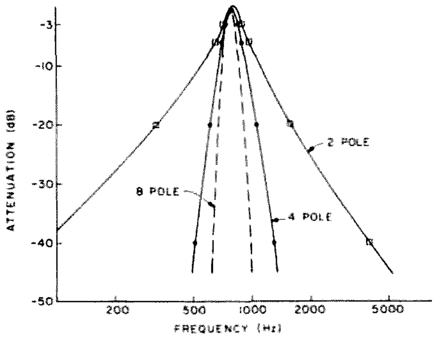

Fig 5. Graph of the response at the various outputs of the active filter. This filter has a center frequency of 800 Hertz and was used as a CW filter.

been made with Firstron Electronics, P.O. Box 151, Streetsboro OH 44240 to supply etched and drilled boards. The cost is $4.00.

Assembly should proceed quickly by following the component location drawing. The usual precautions should be observed when handling the CMOS integrated circuits to prevent damage by static charges. Capacitors shown with polarity are either dipped tantalum or vertical electrolytic types.

When the assembly phase is over, double-check the polarity of polarized capacitors and make sure there are no solder bridges across adjacent foils.

Operation

The dc power supply voltage is not critical. Any voltage between 3 and 15 volts will suffice. With power applied, check the voltage on pin 3 of the LM324. It should be very close to half of the supply voltage. If it is not, the output waveform will be clipped, causing distortion.

Both the input and output of the filter are ac-coupled, so there is no need to worry about disturbing the bias voltages of the preceeding and succeeding stages of the equipment the filter is used with. In order to maintain a linear response though, the level of the input signal must be less than the dc supply voltage. For example, if a 12-volt supply is used, the peak-to-peak input voltage must be less than 12 volts.

For RTTY operation, two circuit boards are required. One for the mark frequency and another for the space frequency. If desired, a ganged rotary switch can be used to select the bandwidths of both channels simultaneously.

Conclusion

The graph illustrates the

Variable Tuning for WEFAX Receivers

—why be rockbound?

In recent years, literally thousands of radio amateurs have discovered the thrill of recovering weather facsimile (WEFAX) images from orbiting satellites. Their efforts and accomplishments have been well-documented in numerous articles—some are listed below as references nos. 1-9—and in at least one excellent book.[10]

Until recently, the majority of weather satellites transmitted VHF-FM images in the 137-MHz region, and enterprising hams have employed their characteristic ingenuity to recover these signals at minimum expense. Receivers which have been successfully modified for WEFAX reception include various Motorola and GE high-band commercial receiver strips, police scanners from Bearcat, Regency, Realistic, and others, monitor receivers such as those sold by Vanguard, Heathkit, Hamtronics, VHF Engineering, and others, and a limitless variety of 2 meter FM receivers.

One characteristic which all of the above receivers share is the lack of tuning flexibility. These are fixed-tuned, crystal-controlled (or "channelized") receivers which, when crystalled and tweaked for WEFAX reception, allow no fine-tuning adjustments. In satellite work, however, manual tuning often spells the difference between marginal and exceptional images (see the accompanying photographs). The purpose of this article, then, is to outline a method of adding frequency tuning to VHF-FM receivers used for weather satellite work.

A weather satellite image received with the incoming signal at the edge of the receiver's passband (some 15 kHz off the frequency).

Why a Tunable Receiver?

Consider an NOAA (National Oceanic and Atmospheric Administration) satellite orbiting the Earth at 900 miles and transmitting weather pictures at 137.5 MHz. As the satellite appears on the horizon, races overhead, and then drops off beyond the opposite horizon, its frequency, as received on the ground, is forever changing. This characteristic Doppler shift, which is well known to anyone who's ever listened to the 2-meter downlink signal from OSCAR VII (Mode B), may amount to several kHz during an overhead pass.

One way to keep the satellite's signal within the receiver's passband is to widen the receiver's i-f bandwidth by the amount of anticipated Doppler shift. But the signal-to-noise ratio (SNR) of the recovered signal is in part a function of the i-f bandwidth. That is, widening the passband response of the receiver admits additional noise, which degrades signal quality.

A costly, though effective, alternative is to keep the receiver narrow, but add an automatic frequency control (afc) loop. The receiver will then lock on to the incoming signal and track it across the spectrum—that is, assuming the receiver is able to acquire the signal in the first place. One disadvantage to afc is that if the receiver loses the signal momentarily due to fading, interference, or whatever, it may be unable to reacquire the signal quickly enough. While searching for a signal to lock on, the system may lose a substantial portion of the transmission.

If an operator is present during reception, manual tuning overcomes the above problem. An operator's search-and-acquire time is minimal (just notice how quickly the pileup materializes when a rare DX station shows up on frequency!), and the operator need only tune to keep the discriminator meter centered once the satellite is acquired.

Consider now the case of receiving signals from

the new generation of geostationary weather satellites.[11,12] Here the satellites are in an eastward orbit above the equator, completing one orbit every 24 hours. Thus, to an observer on the ground, the satellite appears to hover motionless in space. This orbit not only minimizes tracking difficulties, but also eliminates relative motion between the satellite and the observer, thus eliminating the Doppler shift problem.[13]

On-frequency reception of the new geostationary satellites (the United States' GOES E and GOES W, Japan's GMS, and the European Space Agency's METEOSAT) presents other difficulties, however. These satellites transmit WEFAX in the microwave spectrum, at 1,691 MHz. Since image format and modulation characteristics are similar to the transmissions from the earlier, polar-orbiting VHF satellites, reception of these new birds is generally accomplished by placing a heterodyne downconverter in front of an existing VHF satellite receiver.[14,15] And it is in the downconversion process that frequency problems crop up.

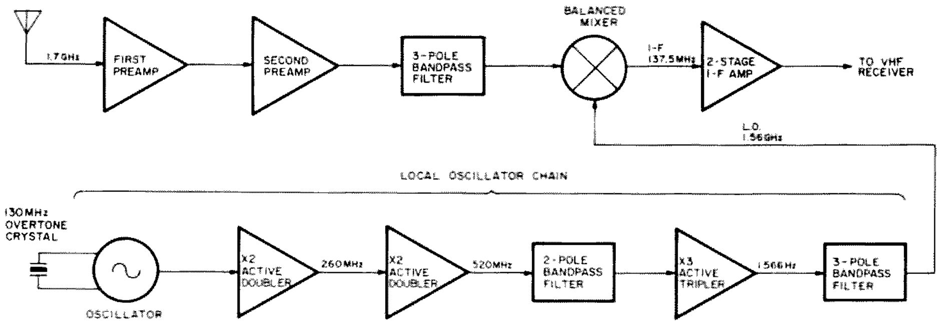

Fig. 1. Block diagram of the Microcomm Model RX-1691 integral WEFAX downconverter. The oscillator/multiplier string is typical of modern microwave receivers. For more information on this downconverter, send an SASE to Microcomm, 14908 Sandy Lane, San Jose CA 95124.

Converter Calibration

A crystal-controlled converter for reception of the microwave WEFAX transmissions might employ a local oscillator in the 1.5-GHz region, derived by multiplying up a stable crystal oscillator in the 130-MHz region (see Fig. 1).[17] A high quality overtone crystal will exhibit a room-temperature tolerance on the order of ±0.001%, which is about five times better than the average ham-rig crystal. This sounds like high precision, but when applied to the 1.5-GHz LO injection frequency, represents a calibration ambiguity of 15 kHz! Since the typical bandwidth of a VHF-FM receiver used as a weather satellite i-f would be on the order of 30 kHz, you can see that even a relatively well-calibrated crystal can easily result in the received signal being on the very edge of the receiver's passband.

Unless the converter's crystal oscillator is installed in a thermostatically-controlled oven, however, the problem doesn't stop there. Over the temperature range of −10° C to +60° C, the thermal tolerance of even a high-grade crystal will be on the order of ±0.002%. Applied to the 1.5-GHz LO frequency required to downconvert microwave WEFAX to VHF, the frequency drift over temperature may be as much as 30 kHz, placing the received signal completely out of the receiver's passband.

Obviously, keeping the receiver "on frequency" with respect to the satellite is going to require some kind of tuning, either to the downconverter's LO or the VHF receiver. I maintain that the appropriate place to introduce tuning is in the VHF receiver. To understand why, it's first necessary to know a little about phase noise.

Phase Noise

An unavoidable characteristic of any crystal oscillator, no matter how well engineered or fabricated, is that it will always exhibit some degree of instability. This is evidenced by incidental

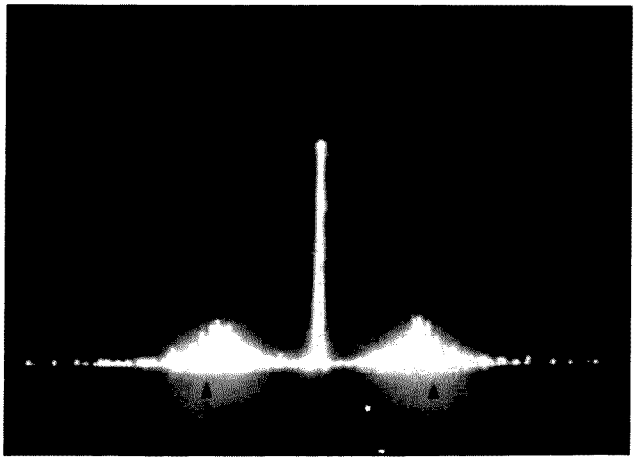

Fig. 2. A spectrum analyzer photo of a microwave local oscillator exhibiting excessive phase noise sidebands. This incidental FM results from excessive pulling of the crystal's frequency of oscillation, as discussed in the text.

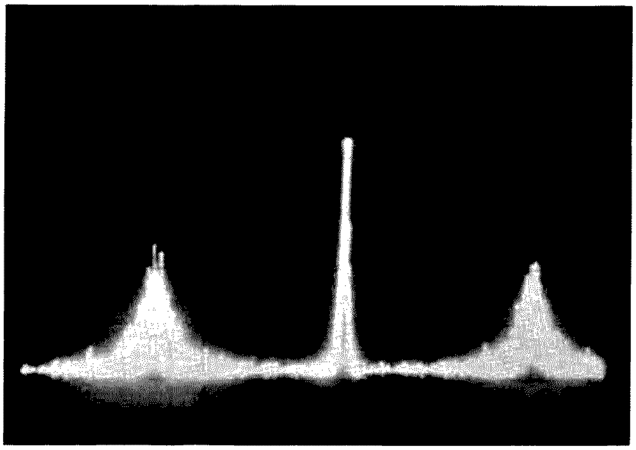

Fig. 3. This is the same LO chain shown in Fig. 2, after having been multiplied in an active doubler stage. Note that both sideband amplitude and deviation are increased, as discussed in the text.

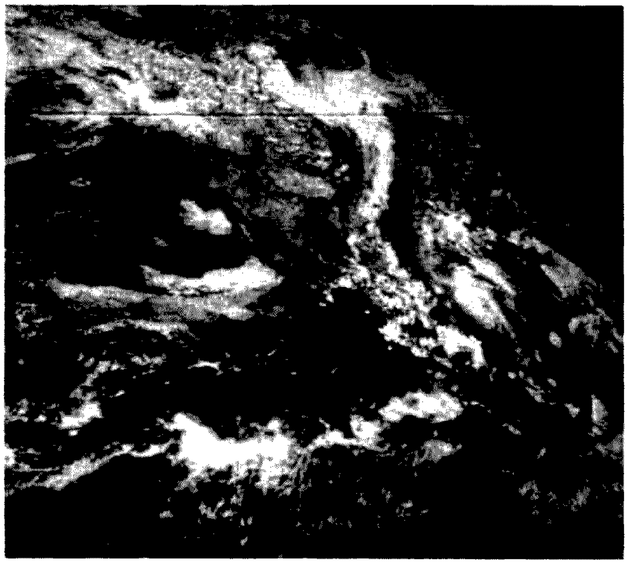

A weather satellite image received with the signal centered in the receiver's passband. All other conditions were identical to those prevailing in the photo where the signal was some 15 kHz off frequency.

FM sidebands visible above and below the primary output frequency, when viewed on a spectrum analyzer (see Fig. 2). In achieving reception which is reasonably free from spurious responses, it is desirable to keep these sidebands (also known as phase noise) to a minimum.

Unfortunately, any time an oscillator's output is multiplied to a higher frequency (such as occurs in the microwave downconverter of Fig. 1), both the amplitude and the bandwidth of phase noise will tend to increase. As illustrated by Fig. 3, phase noise bandwidth increases because, as a signal is multiplied in frequency, the spacing between sidebands is multiplied by the same amount. The increase in phase noise amplitude with multiplication relates to multipliers being nonlinear (generally class C) devices. Think of a multiplier as an amplifier being driven into saturation. The primary signal will be gain-compressed to a greater degree than its sidebands (which, after all, started out at a lower level). Thus, the sidebands emerge from the multiplier nearer in amplitude to their carrier than they were going in.

Since both phase noise and its increase with multiplication are unavoidable, it is apparent that one objective of receiver design should be to minimize incidental FM on local oscillators to the greatest possible extent.

Which Oscillator to Tune?

Any crystal-controlled oscillator can be made to vary somewhat in frequency by placing a small reactance (either capacitive or inductive) either in series with or in parallel with the crystal. The circuit configuration used, amount of tuning achieved, and reactance values chosen are a function of several variables which are, as the textbooks say, beyond the scope of this course. The technique of varying or "warping" the crystal's resonant frequency by the addition of an external reactance, however, is used in most commercial variable crystal oscillators (vxo's) and CB "sliders." The only problem which this technique presents is that "rubbering" a crystal's operating frequency *always* degrades its stability somewhat, and this instability shows up as incidental FM, or phase noise.

Fig. 4. is a simplified block diagram of a microwave downconverter (such as that shown in Fig. 1), operating into a typical VHF-FM receiver. It illustrates the frequency schemes used in the various conversions. You will notice that there are three separate crystal-controlled oscillators involved. Vxoing any one of the three will result in varying the frequency response of the receiver, but which oscillator should be tuned?

Since tuning any oscillator introduces instability, and since instability compounds when frequency is multiplied, it should be evident that we can rule out vxoing the microwave local oscillator chain. This is unfortunate, because the high-order multiplication scheme used would have made it very easy to achieve a considerable amount of frequency flexibility, were phase noise not a factor. That is, the x12 multiplication of the 130-MHz crystal oscillator would have made it possible to achieve ±24 kHz of tuning range just by pulling the crystal up or down 2 kHz. Lest you be tempted to pull the 130-MHz crystal, even this small amount, look again at Fig. 2, which is a spectrum-analyzer photo of the instability which will result.

In the interest of minimizing phase noise sidebands, it always is best to let oscillators driving multiplier chains oscillate where they want to, and do your tuning downstream. Since the output of the 10-MHz oscillator is not multiplied at all, one might be tempted to make it variable, in order to tune the receiver shown in Fig. 4. However, notice that the last conversion stage occurs *after* the 10.7-MHz bandpass filter which sets

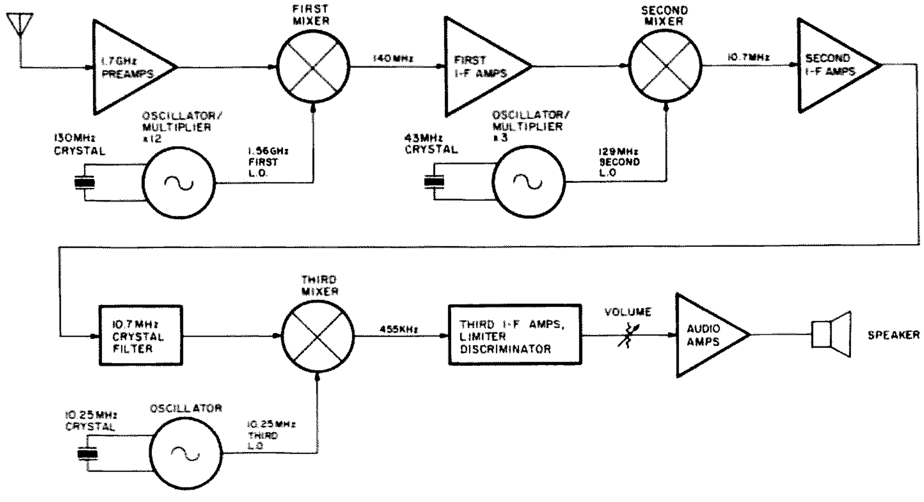

Fig. 4. A simplified block diagram of the microwave receiving system.

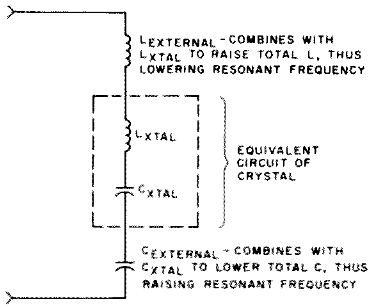

Fig. 5. Varying the operating frequency of a series-mode crystal.

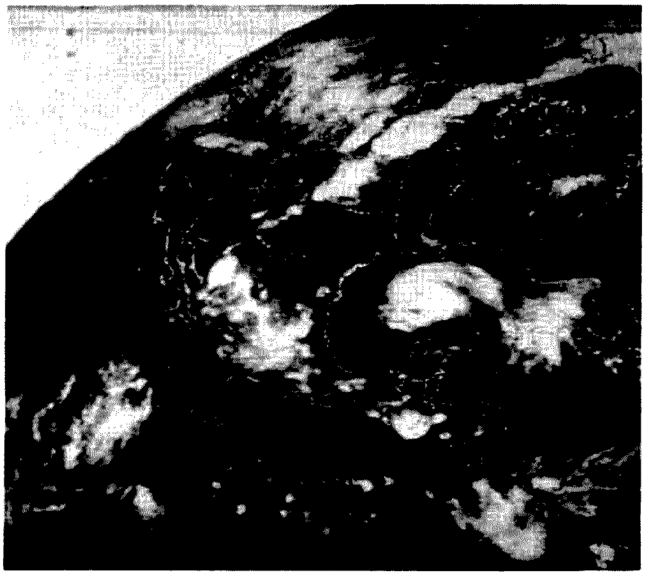

This is a weather satellite image taken with the signal centered in the receiver's passband. Notice the slight blur at the top, caused by tuning the receiver during reception.

the receiver's overall response. Since it does little good to do your tuning downstream from the major selectivity portion of the receiver, this leaves only the 42-MHz crystal in the second conversion as a likely candidate for achieving frequency agility.

It is true that the output of the 42-MHz crystal is multiplied to 126 MHz, and true that that multiplication will tend to aggravate the phase noise problem, but a times-three multiplication is less horrendous than a times-twelve jump, as far as instability is concerned. My experience indicates that it's possible to pull the frequency of oscillation of the 42-MHz crystal as much as ±10 kHz (yielding ±30 kHz of overall tuning range) with no ill effects.

Vxo Circuit Description

I said before that reactances can be added in series or in parallel with a crystal, and that they can be capacitive or inductive to achieve tuning. In the case of a crystal operating in its series-resonant mode, the addition of series-inductance will tend to lower the operating frequency, while series-capacitance will tend to raise it. This is illustrated in Fig. 5. Series-inductance will combine with the equivalent inductance of the crystal itself, lowering the resonant frequency. On the other hand, a capacitor in series with the crystal's equivalent capacitance will *decrease* the overall capacitance, raising the resonant frequency. Where both series inductance and capacitance are used, one effect or the other will predominate, depending on which reactance is of the greater magnitude. If the added inductive and capacitive reactances are equal, they will cancel each other (resonate), and the crystal will oscillate on its original frequency.

Fig. 6 is a schematic diagram of the oscillator section of a Vanguard receiver, which is typical of many of the receivers mentioned in the introduction. The crystals are third-overtone units in the vicinity of 42 MHz, operating in their series mode. Notice the 5-to-30-pF trimmer capacitor, shunted by a 10-pF fixed capacitor, in series with each crystal. These capacitors are used for "netting" or zeroing the receive frequency, and provide a total tuning range of about 2 kHz, upward. To make the receiver come out on frequency, the manufacturer specifies crystals cut for 1 kHz lower than the expected frequency.

Since the 2-kHz total tuning range (±1 kHz) is hardly sufficient to compensate for Doppler shift or thermal drift, it is necessary to significantly increase the tuning range of this circuit. In my WEFAX receiver, I wanted to be able to tune 137.5 MHz ±30 kHz (a total tuning range of 60 kHz). Since the output of the 42-MHz oscillator is tripled to 126 MHz, it was necessary to make the oscillator tune a total of 20 kHz. I found, however, that no matter how small I made the series capacitance, the circuit dropped out of oscillation before it reached 20 kHz of frequency change. Similarly, a series inductor raised the frequency of oscillation, but the circuit died before a 20-kHz change had been achieved.

I was able, however, to make the oscillator move either up or down about 10 kHz by applying about 300 Ohms of inductive or capacitive reactance in series with the crystal. It thus became clear that my vxo circuit was going to have to incorporate both inductance and capacitance to achieve the desired tuning range.

The values which I ultimately selected are shown in Fig. 7. This circuit gave me the desired 60 kHz of total receiver tuning range, but for reasons which I do not fully under-

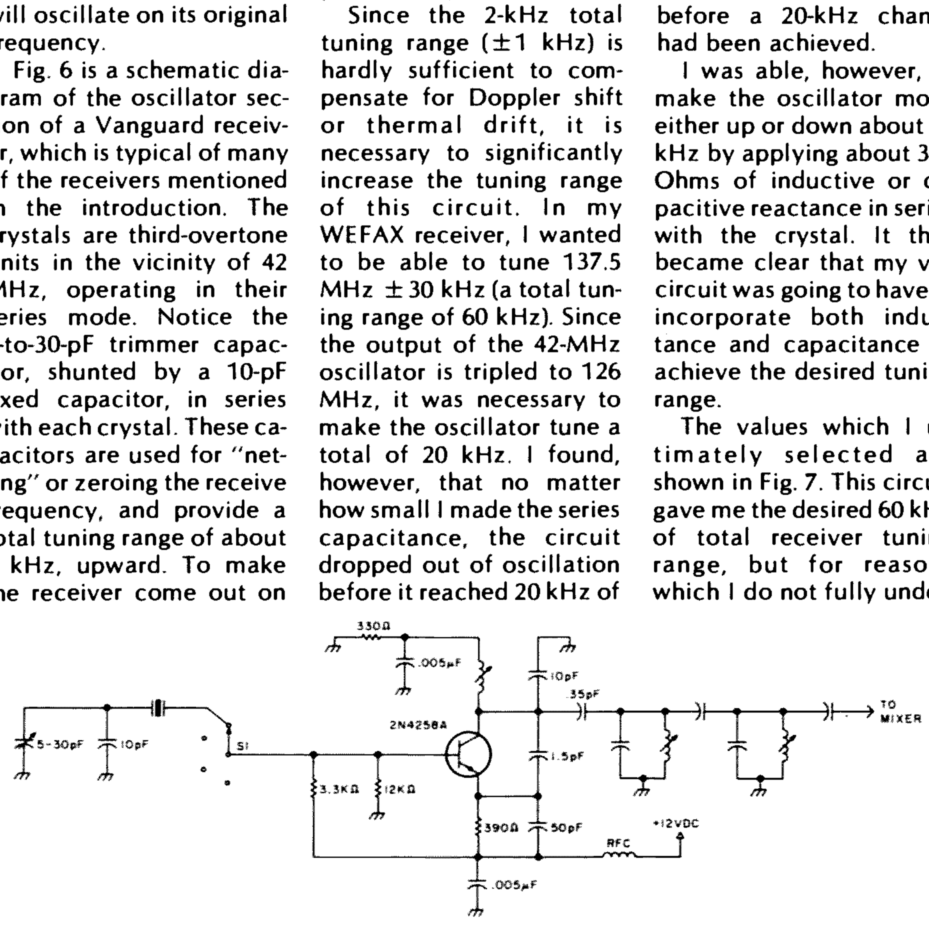

Fig. 6. VHF local oscillator section of the Vanguard FMR-250-11 and FMR-150A FM receivers.

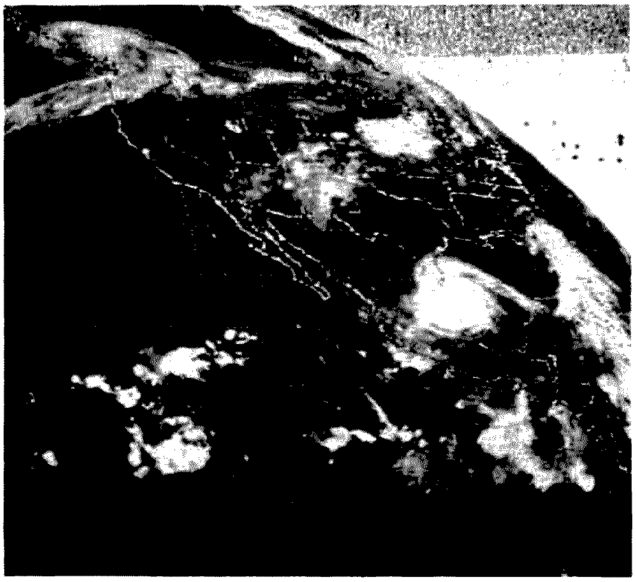

The blur at the top of this picture is a dramatic indication of the effects of tuning. At the start of the transmissions, the receiver was not tuned on the incoming signal. The noise disappears abruptly when the receiver is tuned. This is especially evident in the grey-to-white transition at the upper right.

stand, the tuning range of the crystal was "skewed" downward somewhat. (I suspect this may have been due in part to the crystal's holder capacitance, which I overlooked in my simplistic analysis in Fig. 6.) By purchasing a crystal cut to receive 25 kHz high in the band, this circuit gave me accurate center-frequency calibration, and plus-and-minus 30-kHz tuning.

Since this vxo circuit worked for a Vanguard receiver, I later tried it in a Drake 2 meter transceiver. With a single crystal for 146.55-MHz reception, I am now able to tune the three popular simplex frequencies of 146.49, .52, and .55.

Modification Procedures

The following procedure applies specifically to the Vanguard Model FMR-250-11 receiver. Of all low-cost receivers, this is perhaps the one most widely used for weather satellite work. The procedure will no doubt be similar for other receivers, although the layout will differ. Those readers modifying Vanguard receivers will be aided by the accompanying photographs.

(1) Remove crystal selector switch S1. (This assumes that single-channel plus-and-minus-tuning performance will be acceptable.)

(2) Remove all twelve "netting" capacitors (5-to-30-pF trimmers) and all twelve 10-pF ceramic disc capacitors located adjacent to the crystal sockets.

(3) Cut away the front of the printed circuit board behind S1 to accommodate the tuning capacitor. Note that two power traces at the very front of the circuit board are eliminated in the process.

(4) Using insulated stranded wire, reconnect the power by jumpering around the traces just cut. Leave the wires long enough to be routed around the tuning capacitor, well behind the front panel.

(5) Install the 3-to-30-pF tuning capacitor in the hole formerly occupied by S1.

(6) Wire from the base of the oscillator transistor directly to one of the remaining crystal sockets. Install the two miniature rf chokes between the other pin of the crystal socket and the stator of the tuning capacitor. (See Fig. 7.)

(7) Order a 42.275-MHz third-overtone crystal in an HC-25 package, specifying series resonance and ±.003% tolerance. Plug in the crystal, and enjoy 137.5 MHz (±30 kHz) tuning!

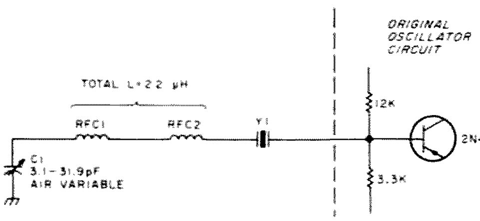

Fig. 7. Vxo circuit for the Vanguard VHF-FM receivers. An added component: Y_1 = 42.275-MHz series-resonant, .003% tolerance, third-overtone crystal, with HC-25 holder (Sentry scanner crystal, cut for 137.525 MHz reception). C1 = E. F. Johnson 1-60-130 air-variable capacitor, 3.1 to 31.9 pF. Rfc_1 = 1.2-uH miniature inductor; rfc_2 = 1.0-uH miniature inductor.

Acknowledgment

Amateurs helping me to evaluate the requirement for tuning flexibility on weather satellite receivers included Ralph Taggart WB8DQT, Dale Hauck W6YFT, John Prigg WA7JIO, and Bob Schloeman WA7MOV. Each of us approached the problem in a different way.

Ralph designed his own VHF-FM receiver from the ground up, with a design which included frequency tuning. Although his circuit employs a tuning varactor diode, it's not too different from mine. He is currently producing the receiver commercially, and from all indications, it should significantly benefit weather satellite enthusiasts.[16]

Dale first tried tuning the microwave LO chain, suffering the very phase noise problems I mentioned earlier. He has since ordered one of Ralph's tunable receivers.

John ordered a synthesizer to go with his existing VHF receiver. The synthesizer gives him fixed-tuned coverage in 5-kHz steps, which is adequate for keeping the received signal rather close to the center of the receiver's passband.

Bob has been using ice cubes, blankets, and lots of luck to try to keep the temperature constant on his microwave downconverter! Though this is certainly the least costly solution of the temperature stability problem, he admits that it does have its weaknesses. By the time this appears in print, the chances are that he will have modified his Vanguard receiver for variable tuning. ■

Ham Radio Marriage Manual

—a YL and her understanding spouse

My reason for writing this article is the tone of surprise or, in some cases, absolute amazement in the voices of my contacts when they learn that I am married to a non-ham.

Not only is the OM not a ham, he doesn't seem to have any desire to be. Since a ham ticket has to be earned at the expense of the individual who wants it, I can not and will not try to push him. He returns this respect by not trying to force on me the—to me, questionable—joys of fishing. The result is that we view each other's hobbies with a kind of head-shaking fascination.

Upon learning that Roger is not a ham, my contacts always ask the obvious question: "How in the world did *you* ever get interested in radio?" The answer usually goes something like this.

There has been a streak of ham in me for years—more years, in fact, than I care to count. It tickles me to remember back to my first year in high school, when my mother and the guidance counselor had to threaten me to get me to take my first speech course. I have silently thanked both of them many, many times since. That first involvement with speech led to what developed into a real love—communicating with people. By the time I finished high school, I was hooked, and it came as no great surprise to my parents that I chose to major in Radio and Television Communication Arts. It was my intention, at that time, to make broadcasting history and revolutionize the communications industry.

Before I finished college, however, and certainly before I had time to gift the broadcast industry with my presence, I married my high school sweetheart. In the years that followed, we traveled around the country at the request of Uncle Sam. Roger was in the Army at the time, and when Uncle Sam invited, it was not an invitation that one could refuse. Of course, our beautiful daughter, who is now nine years old, came along. I never lost my love of people and the enjoyment of exchanging ideas and thoughts.

In 1971, I met Marie WB5OKV, who later became my "Elmira." She was not a ham, but her OM, at the time, was. A few years after we became friends, she began studying for her license. By this time, we were close friends, and I wanted to help her if I could. About the only way I could help was to read her the questions from the license manual. I had no idea what I was reading, but after a while managed to be able to gather whether or not she was right. Most of the time, she would know if she was right or not when I would say, "It says here . . ." At any rate, she told me it was a help to her—maybe she was just being nice.

At this point, I still had not been bitten by the bug. Naturally, after getting her ticket, that's all she talked about. She suggested that I might enjoy ham radio and offered to help me study. At first, of course, I thought I'd never be able to understand all that theory and the code, but after a few months, it finally dawned on me that an amateur radio license was my passage to anywhere I wanted to go. With the cost of living index going up faster than my weight (a phenomenon in itself) and no end to inflation in sight, the only way I could ever see all the places I wanted was through the eyes of the people living there.

So I took Marie up on her offer of help, borrowed her study material, and set out upon what would become a long journey.

I told Roger what I wanted to do, and he said he thought it was a fine idea. The code was the worst thing I had ever tried in my whole life, and theory was about as clear as mud. After a while I became very discouraged, which I have learned since is quite natural. All of you who have ever been in that position will remember. First, you think to yourself, it's not that important, anyway. After all, you've gotten this far in life without it. Right? Then we all realize that we do want it, and the deep-down want-to takes over again and we decide that we will get it no matter how long it takes.

After weeks of study, worry, code practice, sweat, and tears, I took the Novice test, administered

by none other than my Elmira, of course. I felt that I had passed, but was nonetheless amazed and overjoyed a few weeks later when the license came in the mail. Marie understood my excitement, and Roger was happy that I was happy.

After that, I studied with a new dedication for that coveted General ticket. During this time, Roger was patient and tried to be cooperative, but he simply didn't understand how important it had become to me. Marie gave me great moral support, listened to my code, and went over theory points with me whenever I asked her to.

In spite of where my mind was, the usual domestic chores had to be kept up with. So, in order to keep pace with both, I would prop the license manual in the window above the sink while doing dishes, and I listened to a tape recording of me asking theory questions while I ironed. There was a list of formulas on the wall above the washing machine, and Roger's patience was really put to the test the first morning he looked in the bathroom mirror and found himself looking at a block diagram of a receiver.

Finally, the big day in February of 1977 was drawing near. I was going to go to San Antonio for the test since the FCC did not come to Laredo. Plans were made for Marie to help watch my daughter while I made the overnight trip. Test time was 8 am, and I knew better than to think I could get up at 3 am, drive 150 miles, and still have an even chance of passing. So I went the evening before and spent a restless, almost sleepless, night. Every time I closed my eyes, I saw swr rushing at me, and when I tried to run, I kept falling over the formula for inductive reactance. Ultimately, I was taken prisoner by an army of capacitors in series.

The next morning, bleary-eyed and battle-weary, I went to the test. The next couple of hours are a blur in my memory, but I left the examination room clutching a form, signed by the examiner, saying that I had passed the required elements for a General license. Believe me, the tires of my car did not touch pavement all the way back to Laredo!

When I pulled up in Marie's driveway, she was seated in front of her radio. (Her shack was in the garage.) Her blank stare of questioning anticipation was transformed into a smile that went from ear to ear when I gave the thumbs-up signal. I still wonder what her neighbors thought as we yelled at the top of our lungs and jumped around like kids on Christmas morning.

Roger was pleased for me and a few weeks later made me a gift of a 2 meter rig for my car. By this time, he had realized that I was serious and was not surprised that for the next many weeks my every spare moment was spent in Marie's shack listening to and, at her gracious invitation, talking to, her friends on the air. These people became my friends, too, and helped me locate a used Swan 500C that was in good shape at a reasonable price.

Of course, even a reasonable price presented a problem for me. Since the household budget was strained to the breaking point, the $300 I needed sounded like the national debt. The only answer was a part-time job. That was no easy task, either, since I had not worked in years. I was able to find one, however, and being aware of my dilemma, the ham from whom I bought Charlie (the name I gave the rig) offered to let me use it while I paid him for it. Heaven doesn't have a corner on the angel market!

We put up my 40/80 meter doublet well in advance of Charlie's arrival, and I spent the rest of the waiting period fixing up the closet of the guest room, which was to be my ham shack. I had decided that the garage was too hot in the summer and too cold in the winter. Besides that, the closet location would allow me to close the door and keep the rig out of sight of small children who might come to visit.

On the evening of October 3, 1977, Marie and I met Charlie at the bus station and rushed home to get him on the air. Ever since then, amateur radio has been a big part of my life and has brought me many, many hours of pleasure.

Thanks to amateur radio, I have met and made friends with some fantastic people. I've spent hour upon hour listening to other people, sometimes not even breaking in. One can learn a lot just by listening (and about theory, too). Even though I may not have anything to contribute to that particular QSO, I still find it interesting to hear others exchange ideas. I have felt the thrill of talking to people in some of those places I may never see and have known the warmth of helping people find out about loved ones.

Do you have any idea how large a child's eyes can get when he talks to Santa Claus on the radio? (Thanks, J.R.) Some of the people I've met on the air I have had the pleasure of eyeballing and some I have not, and there are others whom I have met that I will never see again because they have become silent keys. I will always cherish their memory.

To me, there is a very real sense of accomplishment in being a ham. Everyone needs to feel the satisfaction that comes from achieving, regardless of age. For me, amateur radio has offered me an avenue of accomplishment, achievement, and pure enjoyment that I have not found anywhere else. I have only regret—and that is that I did not find it sooner.

When I came home after finally passing my Advanced test (suffice it to say that I did not pass it the first time I took it), Roger asked me if I was finished yet. He isn't usually given to such foolish questions!

The bottom line to all this is that if you want a ham ticket, hang in there. For some, the code and theory come more easily than for others. But there is one thing true of every ham in the world—none of them was born with a knowledge of electronic theory, and I assure you that not one of them ever said his first word in CW. We all had to learn it. When I first began studying, I thought ac was the brand name for a spark plug, dc was where the President lived, and CQ was duty that the OM used to pull in the Army!

Don't be dissuaded if you're living in a home without a ham. When you do get your ticket, you will be able to count yourself special because you had more obstacles than most. In any case, don't be scared off by thinking amateur radio is no place for a woman. There are hundreds of us girls on the air. Of course, there are a few guys around who still think that amateur radio is a man's world, but they are few and far between. Ninety-nine point nine percent of the time you'll be welcomed with open arms, as I was. ■

The Space-Saving Square Vee Antenna

—a directional radiator for cramped quarters

Photo A. The 10-meter square vee supporting a nine-year-old helper.

Want an electronically rotatable array, but can't afford the vertical height required for a sloper system[1] or a perverted double vee?[2] Don't have an extra acre or two for a good radial system on your phased verticals? Maybe the DJB Square Vee is for you.

Here's an antenna only a quarter-wavelength high, supported by a single mast, that doesn't depend on a good ground system for efficient radiation. It is electronically rotatable, doesn't require an antenna tuner, doesn't require retuning as the pattern is rotated, and has both high- and low-angle lobes useful for both local and DX work. This is an antenna that could be tacked to the side of an apartment house or, on the high frequencies, easily could be made collapsible for portable or field day operation. Interested? Read on!

Design

The heart of the system is the 3/8-wavelength dipole.[3] A diagram of this dipole, which is 25% shorter than a normal half-wave antenna, is shown in Fig. 1.

The dipole is formed from two $3\lambda/8$ sections of 300-Ohm twinlead. The first section is connected to the second with a 1.5-inch-long piece of twinlead, twisted as shown. The ends of the dipole are at a voltage maximum and must be separated by cutting the ½-inch space shown in Fig. 1. The feedline, a $\lambda/4$ coaxial matching section discussed later, is attached directly to the antenna feedpoint.

The $3\lambda/8$ dipole has not been used widely in the past by amateurs. In part,

this is due to its odd radiation resistance (about 200 Ohms) and to its physical complexity. The square vee takes advantage of both of these apparent drawbacks.

In the square vee, two 3λ/8 dipoles, each bent in the shape of a vee, are mounted vertically with the feedpoints spaced a quarter-wavelength apart. For high frequencies, the antenna can be mounted on a wooden cross, as shown in the schematic of Fig. 2. At lower frequencies, a mast can be used for vertical support with guy wires pulling the feedpoints apart.[2]

The two dipoles are connected in parallel at the phasing control box, which is located in the station operating room. This device is used to adjust the relative rf phase between the dipoles by changing the length of their feedlines. The pattern control box, therefore, allows the pattern of the antenna to be rotated in the same manner as an array of phased verticals.[4,5]

Construction

An example of a ten-meter square vee supported by a wooden cross is shown in Photo A. Each crosspiece is cut slightly longer than a quarter wavelength. The two pieces are joined at the center, and the feedpoints of the two dipoles are connected near the ends of the horizontal crosspiece, as shown in Fig. 2.

Of course, it doesn't really matter whether you use a cross-type support or a simple mast with guy wires. Remember, though, for *all* types of vertical directional arrays, use a nonconducting support such as a wooden mast. A metal mast in the plane of the radiating elements can strongly influence the electrical behavior of the antenna, and may result in disappointing performance. The square vee has a real advantage over the sloper array or the perverted vee in this regard, as it requires only a quarter-wavelength mast rather than a half wavelength or so. On 40 meters, this means the difference between a 34-foot mast, required for the square vee, and the 50- or 60-foot masts required for the other systems.

Using 300-Ohm twinlead makes construction of the 3λ/8 dipole simple. Two sections of 300-Ohm twinlead are cut to 3λ/8. The wires, but not the insulation, are cut at the centers to form the interconnections, as shown in Fig 1. A 1.5-inch piece of twinlead is used to connect the first section to the second. Be certain to separate the wires at the ends of the dipole, and leave about half an inch of space between the ends of the wires (see Fig. 1).

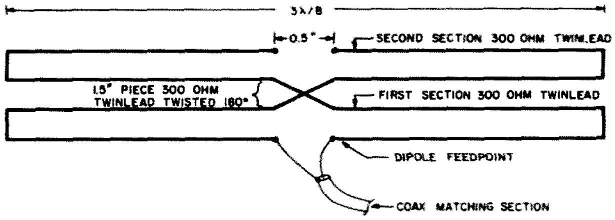

Fig. 1. Schematic drawing of the 3/8-wavelength dipole.

For each dipole, the first section of twinlead is mounted on one side of the horizontal crosspiece, and the second section is mounted on the other side. The 1.5-inch connection at the center (see Fig. 1) feeds through the horizontal support as shown in Photo B. This method of mounting keeps the wires of the dipole properly spaced. The ends of the twinlead can then be attached to the top and bottom of the vertical mast. I used small wire brads tacked through the center of the twinlead near the end. Before the ends are permanently attached, however, it is best to secure them temporarily with tape and check the antenna tuning.

Tuning

For maximum performance, it's very important that the two dipoles be electrically equivalent. Beg, borrow, steal, or perhaps even buy a grid-dip meter or similar instrument and trim the lengths of the dipoles to resonance at the desired frequency. I found that the length had to be slightly shorter than three-fourths of the length predicted by the traditional formula $L(\lambda/2) = 468/f$ (MHz), where $L(\lambda/2)$ is the length of a half wave in feet. Two factors probably accounted for this. First,

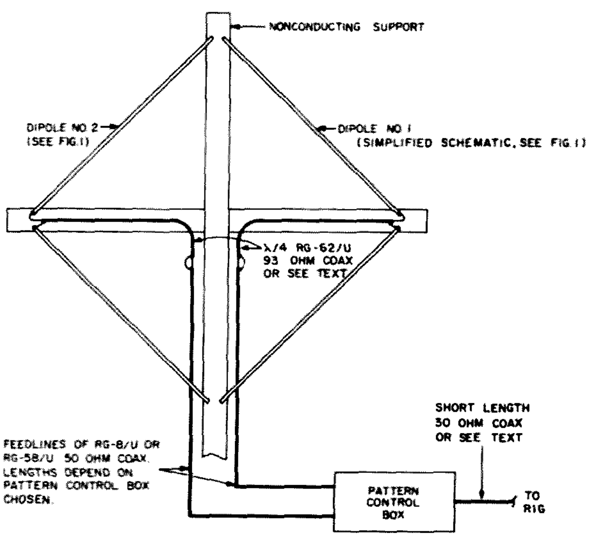

Fig. 2. The square vee antenna supported by a mast and crosspiece. The pattern control box is located inside the operating room near the station.

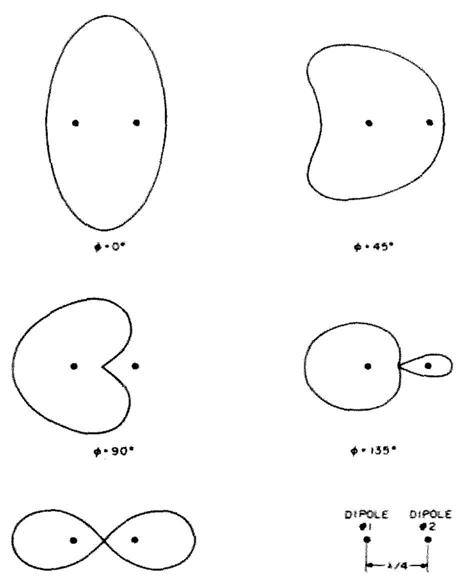

Fig. 3. Antenna radiation patterns in the horizontal plane for two vertical dipoles spaced a quarter wavelength apart.

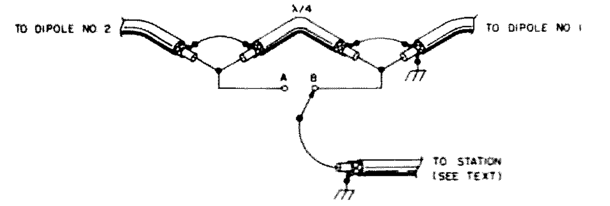

Fig. 4(a). Circuit of the pattern control box for phasing steps of 180°.

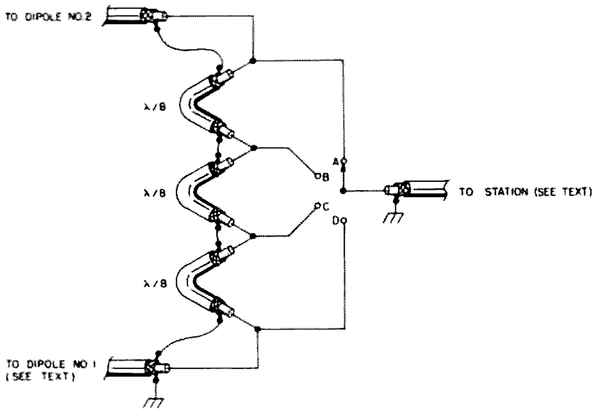

Fig. 4(b). Circuit of the pattern control box for phasing steps of 90°.

the formula doesn't include the one-inch interconnection between the two twinlead portions of the dipole, Fig. 1, and, second, the formula is good for a linear dipole and not a dipole in the shape of a vee. You probably won't go too far wrong if you cut the dipole length 1% shorter than that given by the standard formula; that is, use $L(3\lambda/8) = 347.5/f$ (MHz).

Antenna Matching

The radiation resistance of a linear 3/8λ dipole, measured high above a perfect ground, is about 225 Ohms.[3] In the configuration shown here, I found the radiation resistance to be closer to 175 Ohms. The radiation resistance of the antenna was lowered both by its vee shape and by its proximity to surrounding objects. It's very important that the swr on each dipole feedline be as close to unity as possible. If it's not, the load on the transmitter will change as the pattern is rotated, and the transmitter will have to be retuned for every direction. What's more, a mismatch here will probably require a matching network between the transmitter and the antenna for proper operation.

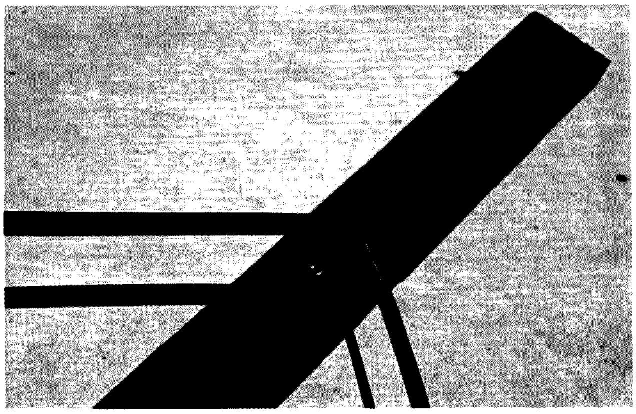

Photo B. Closeup of the dipole feedpoint near the end of the crosspiece. The coaxial line feeds through the wooden crosspiece to connect to the dipole.

A quarter-wave matching section of 93-Ohm coax, such as RG-62/U, makes a good match between the 175-Ohm antenna resistance and 50-Ohm coax feedline. We calculate this from the formula $Z_1 = Z_o^2/Z_r = (93)^2/175 = 49.4$ Ohms,[6] where Z_o is the impedance of the quarter-wave matching section, Z_r is the radiation resistance of the antenna, and Z_1 is the impedance at the feedpoint of the quarter-wave matching line.

Instead of the quarter-wave coaxial matching network shown in Fig. 2, a 4:1 balun transformer (Amidon Associates kit) could also be used.[7] The balanced, high impedance side of the balun would be connected to the antenna feedpoint, and the low impedance side to the 50-Ohm coax feedline. This should work especially well in installations where the radiation resistance of the dipoles appears closer to 200 Ohms than to 175 Ohms.

Phase Control

The 50-Ohm feedlines, RG-8/U or RG-58/U, run down the vertical mast into the operating room, and connect to the pattern control box. The pattern control box selects the relative rf phasing between the two dipoles and allows the directivity of the antenna to be changed. Fig. 3 shows the horizontal antenna patterns that can be expected from two dipoles a quarter wavelength apart, as θ, the rf phase angle between them, is changed. Of course, the shape of these patterns depends upon the incident angle of the incoming radiation, and the expected performance is modified further by the vee shape of the individual dipoles.

	Switch Position	Phase Shift
Equal Length Feedlines	A	+90°
	B	−90°
Feedline #1 90° Longer Than Feedline #2	A	180°
	B	0°

Table 1. Phase shift between dipoles #1 and #2 as a function of switch position for the pattern control box of Fig. 4(a).

Fig. 4(a) shows an elementary switching network that can be used to select between the 0° and 180° patterns, or between the +90° and −90° patterns. (The −90° pattern is the reverse of the +90° pattern.) For the 0° and 180° patterns, the feedline of dipole #1 must be a quarter wavelength, or 90°, longer than that of dipole #2. For the ±90° patterns, the feedlines must be equal length. Table 1 shows phase shift versus switch position for the difficult feedline lengths.

In calculating the electrical length of the feedlines, be sure to measure the physical length very carefully, and include the effect of the velocity factor for the coax you use. The velocity factor for solid dielectric 50-Ohm line is 0.66, and the velocity factor for foam dielectric line is 0.80.

The circuit diagram for a more versatile switching network is shown in Fig. 4(b). This network allows the antenna phasing to be switched in 90° increments, and requires that the feedline for dipole #1 be one eighth of a wavelength, or 45°, longer than the feedline of dipole #2. The phase shift (as a function of switch position) for this circuit is given in Table 2.

If desired, a more complex network employing an

eight-position switch could be used to select antenna patterns at 45° intervals. This would require that the feedline of dipole #1 be 22.5° longer than that of dipole #2, and would require one sixteenth of a wavelength of coax (22.5°) between each switch position.

Station Matching

If the dipoles have been carefully matched to the line, the termination impedance at the end of each feedline will be very close to 50 Ohms. When the two dipoles are connected in parallel at the pattern control box, the feedpoint impedance at that point will be 25 Ohms. There probably are a number of ways to match this 25-Ohm resistive load to your transmitter. If the output circuit is capable of matching a 25-Ohm resistive load, you can couple it directly to the pattern control box through a *short* (compared to a quarter wavelength) piece of 50-Ohm coax. Or, you can connect the pattern control box and the transmitter with a half-wavelength of 50-Ohm coax. The latter solution is better at the high frequencies; even though the swr on the line is about two, its short length prevents significant losses.

The technique I used was to connect a quarter wavelength of 73-Ohm RG-59/U from the pattern control box to the transmitter through a balun step-down network. The quarter-wavelength of 73-Ohm line transforms the 25-Ohm feedpoint at the pattern control box into a 213-Ohm load. We see this from the equation used previously, $Z_1 = Z_0^2/Z_r = (73)^2/25 = 213$ Ohms. At the transmitter end of the quarter wavelength, I used a 4:1 balun with the low impedance side connected to the transmitter to transform this in- to a 53-Ohm resistive load. This is a little bit more trouble, but provides an excellent match to pi networks designed to operate on 50- to 75-Ohm resistive loads.

Performance

I built my first square vee for the 10-meter band and used the pattern switching arrangement shown in Fig. 4(b), i.e., phasing steps of 90°. I mounted it on the roof approximately 20 feet off the ground, underneath a 40-meter inverted vee. The antenna required only minor retuning of the transmitter as the pattern was rotated, and I found that with about 100-Watts output, I could work almost anyone I could hear. A large number of European, East Asian, and Oceanic stations were contacted on both SSB and CW with a call-per-contact ratio for DX of about 80%. In other words, it works.

The big advantage of the antenna, however, lies in its directional performance. A large number of tests were performed on both receiving and transmitting, and it was found that the front-to-side ratio between the 0° and 180° phasing positions was about four S-units. As the patterns are not symmetric, the front-to-side ratio between the 180° and 0° patterns is different—and this was found to be about two S-units. The front-to-back ratio between the +90° and −90°phasing positions also was found to be about two S-units.

As an example of the directional performance, let me describe an actual contact with this antenna. With the 0° phasing pattern, I had maximum gain to the northeast, and was listening to a W8 station at S6. In between pauses, I heard a weak station, at about S3, calling CQ. Rotating the pattern to 180° phasing knocked the W8 down to S2 and brought in the other station at S5. It was an RAØ, and one call to him made the contact. Play with this for a couple of hours and you'll never go back to an omnidirectional antenna.

Switch Position	Phase Shift
A	180°
B	90°
C	0°
D	−90°

Table 2. Phase shift between dipoles #1 and #2 as a function of switch position for the pattern control box of Fig. 4(b).

Summary

Here's an electronically rotatable antenna that's 44% smaller in area than a single quad loop, stands only a quarter-wavelength high, and doesn't require retuning as the pattern is rotated. Of course, this antenna won't outperform a full-sized yagi/tower combination on the high frequencies, or an array of phased verticals with an extensive ground system in an open field on the low frequencies. And, like all electronically rotatable arrays, the shape of the pattern changes with the direction chosen. But at moderate heights, and with no special ground preparation at all, it appears to do a first-class job.■

which might be covered on the exam. I have heard them saying they arose at 5 am to practice their code. This is nonsense.

The best asset to bring to your FCC examination is a relaxed mind. The best way to assure this is to go to bed early the night before and to do nothing of a technical nature upon awakening. No code practice, no last-minute peek into a textbook, no checking out of cram slips. Instead, have a relaxing shower, a good breakfast, a look at the morning newspaper—anything but ham radio. In this way, you arrive at the examination site with a mind that is capable of leisurely comprehending the code that will be sent to you.

The Written Exam

Let's say that you've taken the code examination, you've been told that you passed, and now you can take your written examination. This is all there is between you and your higher class license. What tips can I offer to help you pass this portion of the exam?

Here are a number of things to keep in mind as you prepare for—and take—the written examination. Follow them and your success is virtually guaranteed.

1. Know your stuff. Very few people get through the exam if they don't know the material. You should get the necessary textbooks and study the material. Become as expert as you can with the technical side, operating procedures, and regulations.

2. Get as much practice as possible working on multiple-choice questions. Most textbooks offer sample questions and answers to give you experience in answering FCC-type questions. Study as many of these questions as possible *after* you've studied the material. Don't use the questions as a method of studying; use them to help you check on your understanding of the material studied.

If you've done steps 1 and 2, you're ready for all those that follow.

3. You now arrive at the FCC office. If you follow the advice given above for passing the CW portion of the exam, you'll be refreshed and relaxed. This condition is as important for passing the theory portion as it is for the CW portion. No last-minute cramming, no peeking into the text to look up that formula one more time, no carrying of sheaves of paper to refresh your memory at the very last minute. Shut off the studying before supper the night before. Let your mind relax.

4. Bring a calculator. This saves mental wear and tear and helps ensure correct answers to mathematical problems.

5. When you are entering the examination room, you will be given the printed test, the answer sheet, and a blank piece of paper for calculations and scribbles. As you sit down, take out the two pencils you've brought along, and for the moment put aside the test booklet and answer sheet. Now, while your mind is still relaxed, write on the piece of paper every formula you feel you may have to use. Write down every item that may be a little shaky in your mind. As long as these formulas and items come from your mind, everything is perfectly proper and legal. Why do this? Because your mind is relaxed and it's easier to recall, say, what the formula is for capacitors in parallel than it is to recall the formula when faced with an actual question. That's how the mind works. Ohm's Law can take on some interesting variations in the mind of a ham who is wading feverishly through an exam.

6. Once you've put on paper all your necessary formulas, open up the test booklet and see what the number of the first question is. Why do this, you ask? Don't all tests start with number 1? Not at the FCC, they don't! This test may start with 1, but it may start with 51, or 101. As soon as you see which number it starts with, take the answer sheet and mark the corresponding number with your pencil. This is where you start to answer questions on the sheet. Basic, you say? Obvious, you think? Yes, but we don't know how many aspiring hams (who knew their theory cold) failed the FCC exam because they gave beautiful answers to questions 51 through 100 in the spaces on the answer sheet marked 1 through 50. In short: Answer the question asked in the booklet at the exact spot on the answer sheet where the answer will be graded.

7. You're now ready to attack the first question. Here's the technique to follow: Read the first part of the question, the part before the multiple choices, but *do not* look at the five answers offered. See if you can mentally determine what the correct answer is before looking at the five choices. For example, if the question says, "The 'Q' signal for 'I am being interfered with' is . . . ," your mind should pause and mentally seek the correct answer—QRM. Once thought, write it down on the sheet of scrap paper. If you don't do this, you are now faced with a confusing array of Q signals from which you must make a choice: QRS, QSK, QRQ, QRM, and QNX. In the pressure of an examination, you might make the wrong choice when faced with this selection. So, for each question, don't look at the answers first. Mentally determine what the correct answer should be, write it down on your scrap paper, and then check the answers supplied to see if your answer matches one of the exam's answers.

8. Having picked out the right answer, indicate it on the answer sheet, and be sure that you put the answer in the right spot (a, b, c, d, or e) and at the right answer number. Don't put a "b" answer in the "c" slot, and don't answer number 73 in the space for number 74. Be alert.

9. Continue this process with each question. At some point, you'll come across a question which you can't answer in your mind. Now what do you do? At this point, look at the "a" answer *only*. Does it seem to be the right one? If so, write "a" on the scrap sheet. And then go on to b, c, d, and e, seeing if a "better" answer appears. If it doesn't, write "a" on the answer sheet in the appropriate spot. If another answer appears that seems to be just as correct, you have to make a judgment as to which is more correct. Once you've done this, write the answer in the appropriate spot. Continue on through the exam.

10. Let's say you come across a question that you can't answer. You review the five answers and none seems appropriate. At this point, write the number of the question on your scrap sheet and go on to the next question. Don't fret. Don't worry. The FCC gives you quite a margin for error in the exam. One question doesn't make much difference. The main thing is to keep your mind at ease, relaxed, and happy. Go on to the next question and let your subconscious mind take over. While your conscious mind is scanning the next question, your subconscious mind will be poring over the question you just passed. At some mo-

ment, the answer just might pop out.

11. Continue with this procedure. Answer the questions you're able to answer. Pass the questions you want to do something about later, after noting their numbers on the scrap sheet. If your mind suddenly gives you the answer to a skipped question, stop in your tracks and return to the question. Immediately write down the correct answer in the appropriate spot.

12. When you have gone through the list of questions the first time, return to the ones you could not answer. Read each question carefully and see if you see something which you didn't see the first time. Many times, a second reading of the question gives you a new slant on what is being asked or on what is being offered as an answer. See if you can pick out the correct answer for each skipped question.

13. If you cannot pick out one answer of the five offered, try to *eliminate* the incorrect answers in an effort to reduce your choices to two or three. When you have done this, pick the best-looking answer and write this on the answer sheet. Having made your decision, go on to the next question.

14. When all else fails, *guess*. Leave no question unanswered. You get no credit for an unanswered question. You may be lucky and guess the correct response.

15. After you have answered every question and have written the answers on the sheet, go back and check each answer on the sheet. Be sure it agrees with the answer you feel is correct. If the answer to 63 is "b", be sure "b" is indicated after 63 on the answer sheet. In the pressure of an examination, most people will incorrectly list one or two answers. By reviewing each answer, you can just about guarantee yourself one or two "extra" points which may be critical in passing the exam.

16. To reduce the tension, consider taking the code on your first visit to the FCC office and the written examination on your second visit. In this way, you can concentrate your mental energy on the task at hand: copying the code at the necessary speed or choosing the proper number of correct answers to questions on theory and regulations. (This splitting of parts of the test is more easily accomplished in cities where the examinations are held weekly or monthly.)

There are only three reasons why anyone will fail an FCC examination:

1. *Lack of preparation*. If you haven't studied your material and if you can't copy code at the required speed (or a little higher), don't waste your time taking the exam. Miracles are not commonplace these days.

2. *Poor testmanship*. Unfortunately, a number of people who do know their stuff and who can copy code at the required speed will fail an FCC examination. This article is designed for this group. By following the principles outlined, any upgrading candidate should find his or her chances of success improved immeasurably.

3. *Nerves*. If you prepare sufficiently and do what this article suggests, you may be pleasantly surprised to find that your "nerves" have disappeared.

Good luck on your next exam! ■

The increasing price and rarity of vacuum tubes and other components in your ham rig make it imperative that it run as cool as possible. Have you ever wondered when those poor, hot components in the rig will finally melt into oblivion? The heat generated by the power-handling parts of the transmitter should be directed well away from the rig, preventing a possibly expensive episode in radio self-annihilation. Fortunately, there's an easy way to alleviate the woes of an overheated goodie in your station.

An electromechanical air mover, commonly called a fan, can be employed to keep things cool when thermal overload becomes imminent. In fact, the electronics industry is utilizing these gems in a variety of configurations more and more frequently as component densities escalate and enclosures shrink. One estimate puts the number of miniature air movers at the all-time high of 80-million dollars worth just last year.[1] With all this expensive hot air blowing around, there must be some good reasons for you to consider installing an auxiliary cooling device in your station.

There are indeed several good reasons for helping your rig stay cool: Components and tubes last much longer, frequency stability is improved with less thermal expansion of coils and coil forms, and smoked capacitors and resistors due to simple overheating just don't occur.

The fans I'll be discussing in this article are the so-called tubeaxial fans, normally known as Muffin™ fans (EG & G Rotron trademark). These things usually

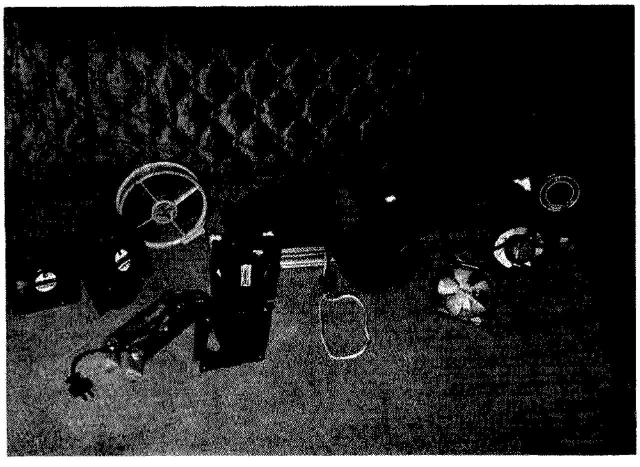

Photo A. A typical collection of fans available at flea markets for under $10. Visible are Pamotors, a Feather, Centaur, Caravel, and Boxer fans.

Photo B. A couple of fine-running Pamotor fans from Germany.

have square or circular housings with an "inside-out" motor—the shaft part of the motor is the fan hub with the moving blades attached. They're by far the most popular and useful fans available to the radio amateur.

Almost all ham rigs today have a well-designed natural air ventilation system called "convection cooling." This simply means that the warm components in the rig heat up the air nearby, causing it to rise and draw cool air in from the bottom of the case. This works great, but the idea (and cooling effect) is tremendously enhanced by placing a fan in the right spot on or by the rig. The result is a much cooler running operation.

Trademark Name	Cfm	Comments	Price
Sentinel	100	Stainless steel ball bearings	$25.00
Centaur CT3A2	100	Sleeve bearings, 15 Watts	16.90
Mark IV Muffin	100	Very popular	12.05
Whisper	65	Super quiet, 6 Watts	12.05
Sprite	35	3½"-square, 11 Watts	14.95
Spartan	110	Military, stainless steel BB	45.50
Feather	270	SS BB	36.85
Saucer	280	SS BB	70.40
Caravel	575	BB	29.70
Tarzan	350	BB	46.65

Table 1. EG & G Rotron fans, with 1970 prices.

Choosing a Fan

I've compiled a list of the most common fans you'll find at a swapfest or surplus store in Table 1. These are the Rotron trademark names, listing the amount of air moved (in cubic feet per minute, or cfm), and some very dated 1970 prices so that you can get an idea of their original market value. Other fine fans are made by Pamotor, of West Germany, and the Boxer fan from IMC Magnetics. Be sure to inspect your purchase for dented or bent blades, and also spin the blades a bit to make sure they turn very freely.

Let me emphasize at the outset that you don't need much in the way of cfm to cool an already well-designed rig. The important operating factor to consider is the noise generated by the mechanical beast. The key to quiet success is a slow motor speed. For example, I put a little 50-cfm Pamotor 4800A (very quiet) on top of a normally frying-hot 17-tube Polycomm 2-meter rig, and the transceiver ran ice-cool thereafter.

So, pick a fan which doesn't take much power (therefore, it will be running slower) and which doesn't have more than about 75 cfm or so of cooling power. However, flea markets and surplus stores often don't have fans which meet such stringent requirements. If you do get a fast, noisy fan, there are easy ways to slow it down, as I'll mention later.

By the way, 220-V fans are ideal for ham applications—they run beautifully on 120 V, retaining 60% of their original air-moving power with only 20% of their original noise, and they're cheaper, too. Surplus companies often offer these at reduced prices because they were not originally specified for the 120-V line. Best buys here are the 220-V Feather, Saucer, and Sentinel, or equivalents.

Mounting a Muffin

The easiest way to determine what part of your rig gets hottest is simply to turn it on, let it warm up, and feel the top of the case for hot spots. Obviously, the area on top of the finals will be warmer than the rest of the radio, so that should be your priority target. If there are other heat-producing components in the rig, you can place the fan so it pulls the most air past the finals and gets the rest of the rig with somewhat reduced air-flow. A larger-diameter fan, properly slowed and quieted, is better for application in all-tube transmitters, while smaller fans do nicely in "all solid-state except the finals" rigs.

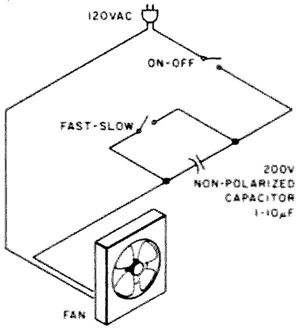

Fig. 1. Schematic of method to slow down a fan with a series non-polarized capacitor, 1 to 10 uF, at 200 WV minimum.

I don't recommend putting fans on receivers. They aren't necessary in a decent rig because there just isn't enough heat generated by its low-power components to warrant auxiliary cooling. If you want to cut down heat in an old-

Photo C. This Muffin fan sits over the finals and is mechanically damped by four felt feet.

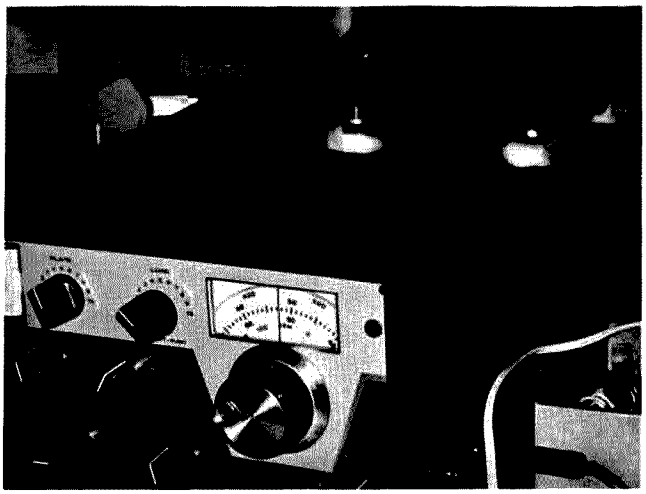

Photo D. A friend's setup with the fan bouncing merrily on four pads of foam rubber.

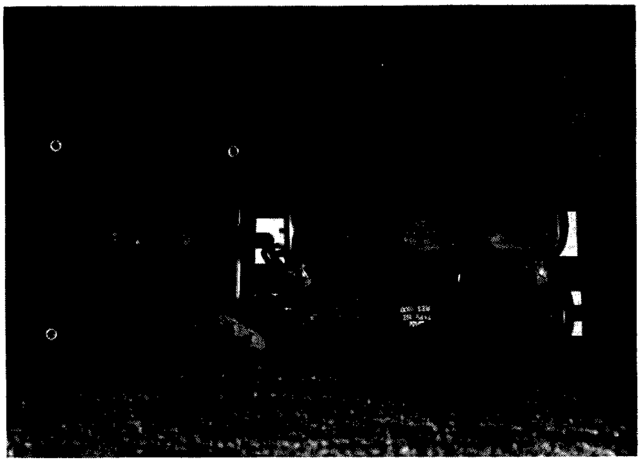

Photo E. The unclassy method of slowing down a fast, noisy fan, with power resistors. These two units need to be mounted in a well-insulated box, or be replaced by a much more elegant capacitor.

er tube-receiver, replace the rectifier tube with its solid-state equivalent (with suitable dropping resistors), and put in an LM-380 audio IC instead of those push-pull 6V6s.

When you mount the fan on your transmitter or transceiver, it's always best to place it on top of the rig so that it aids the natural tendency of hot air to move up and out. Don't try to blow air through the rig—just pull the hot stuff up and away. This makes it imperative that you keep the radio elevated on its mounting feet (don't take them off to save space), and that the area beneath the rig is kept as dust-free as possible. A too-powerful fan will suck dust and debris into your transmitter's innards, and a mild airflow is really all you need to keep the radio cool and clean.

You can kill potential mechanical vibration problems by sticking some foam rubber tape or thick felt under the fan. There's no need for an airtight connection between fan and case; just put something between them as a mechanical damper. The Pamotor I use has four felt pads glued to its underside, one in each corner, which work fine.

Quieting All That Coolness

As I mentioned above, the number one requirement for your fan is that it run quietly. In fact, plenty of air will circulate at the minimum noise level when the fan is running just a little faster than the rpms necessary to keep it going. How do you accomplish this with an ordinary Muffin?

There are two ways. First, you can put a 350-Ohm power resistor in series with the fan, experimenting with the values until it runs the way you like. This, however, generates heat—an advantage only if you have a cold basement shack and need a footwarmer! You should be very careful to thoroughly insulate the resistor from the outside world lest a shock hazard be created. Put it in a bakelite box with vent holes—and no, you don't need another fan to cool the resistor.

The second way is slightly more elegant, generating no heat. Simply put a 1-to-10-uF (again, experimenting with the values) non-polarized capacitor in series with the fan. Those old Pyranol non-polarized metal-cased capacitors clunking around in your junk box will work fine; you need at least a 200-V rating here. Don't use electrolytics—they aren't made for pure ac work. If you like to play with numbers and simple math, it's an easy matter to calculate how much capacitance you'll want. You need to know Ohm's law, the formula for capacitive reactance, how much power your fan draws, and how much voltage you want it to run on. For me, however, it's easier to slap in a few microfarads and see how fast she goes.

Fig. 1 shows a simple schematic of the fan and capacitor; I've added a switch across the capacitor so that you can zoom to full speed when you want to cool yourself off after a hot day's work at the rig. Again, be sure to put the capacitor and switches in a well-insulated box so that there's no chance of a shock. Be careful when you're experimenting with values—there's 120 V floating around on your connections.

Of course, if you have a 220-V fan, chances are it'll run slow and quiet by simply plugging it into 120 V. Just add some felt or foam padding to its mount, plop it on top of the rig, and be amazed how coolly the station runs.

The accompanying photos show evidence of a friend's mania for collecting these wonderful fans. Oddly, he never replaces tubes or other components in his well-used equipment. You'll have the same fantastic results when you simply and easily cool off the overheated parts in your own rig. ■

Are Repeaters Ripping Us Off?

—some thoughts about open access to scarce frequencies

Something has always bothered me about repeaters. It's never been anything like hatred or even a serious gripe. I've only felt a vague uneasiness when reading about them, thinking about them, or, lately, when using one. It's as though something were not quite right, and as hard as I've tried, I've never been able to put my finger on it.

I came up in hamdom from the Novice ranks using junky eighteenth-hand gear, and it was not until recently that all those classy multi-hundred-dollar FM portable transceivers fell within reach. So it still strikes me as odd that people will earnestly ask, "QRZed the frequency?" when no living soul is calling them on *any* frequency. Each new country has its own language, I guess, and I decided my uneasiness was only the acclimatization lag time of a stranger in a strange land.

The tales of repeater wars and users'-rights conflicts in LA amused me. One night while we slept, I supposed, the Good Lord tipped America on its side and all the loose nuts fell into southern California. No, Californians aren't any crankier than the rest of us, just noisier. If they're fighting about someting in LA, they're probably fighting about it—more quietly—everywhere else. My uneasiness remained, getting stronger every time I heard a new repeater take to the air.

Last fall I traveled east with my brand-new synthesized portable, clicking my way across the band on those marvelous magic thumbwheels. Repeaters were everywhere, and I talked on quite a few. There were many more which just didn't seem to hear me, regardless of how close I was. By the additional magic of PL™, they had shut themselves off in a world of their own, occupied by a few dozen calls and no more. My uneasiness got pretty intense listening to those unreachable machines, but I figured it was just sour grapes. My affable, rational side told me it takes all kinds to make a world and that there was plenty of room for everybody.

On a beautiful hill in Virginia, not far from Washington DC, I chose a quiet spot on the band and tried to see if I could latch into an apparent tropospheric duct and make some 2-meter distance. No one had spoken on that frequency since I had turned on the rig (about twenty minutes before), so I did the unthinkable and called "CQ 2 meters." A "good ol' boy" voice came back immediately and told me to kindly get off his private repeater input.

I'm used to 20 meters, perhaps a little more than I should be. When somebody says, "This frequency is in use," I apologize and scram. So, standing on my beautiful Virginia hilltop, I apologized and scrammed. It didn't hit me until late that night, while in the shower with a cold spray on my face, that my hilltop frequency had *not* been in use for at least twenty minutes. "Cool off, Chief," I told myself. "After all, it was his frequency." *His* frequency?

Like hell!

Suddenly, everything which had ever bothered me about repeaters became as clear as cocktail ice. I laid hands on a license manual and thumbed frantically until I found the paragraph in the rules which had eluded my thinking:

> 97.63. Selection and Use of Frequencies. (a) An amateur station may transmit on any frequency within any authorized amateur frequency band.

That seems pretty plain to me. Every ham who sweats his way into pos-

session of a license shares all frequencies permitted his license class. Nobody can stake out a point on the radio dial and defend it against all comers. 'Tain't legal, friends.

One outcome of Repeater Appreciation Day in LA was the demonstration of the fact that a repeater is an extension of the repeater licensee's home station. The only user with any rights is the repeater owner. Everybody else is a guest in the man's shack, and the owner may set any rules for guests which he desires. This seems to include limiting guests to whichever group the owner desires to have use the machine. That seems to make sense. After all, he paid for the repeater, and he keeps it running.

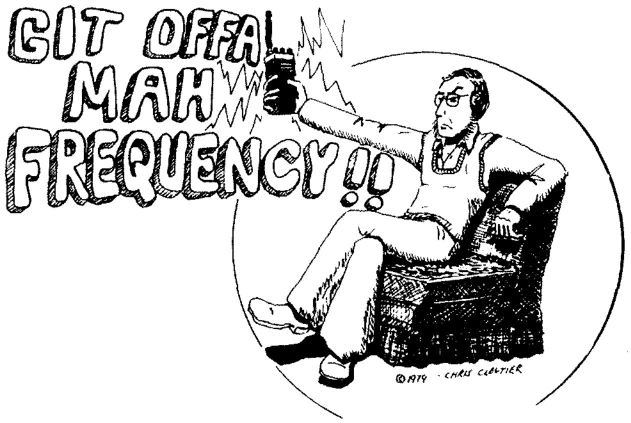
So much for the machine itself. But what about the *frequency*? A great many repeaters in urban areas now operate twenty-four hours a day. That means that, in effect, one man's ham station is sitting on a pair of frequencies for what may turn out to be years, with breaks for maintenance only. If I did that on 20 meters, they'd lock me up and throw away the key.

Of course, a repeater's carrier is not on at all times. But every ten minutes, like clockwork, comes the little announcement of callsign, location, local time, temperature, and God knows what else. In the wee hours of the morning, the repeater may not be keyed up for hours on end. But you can bet that, should a friend and I attempt to work simplex on the repeater's input frequency on any regular basis, a gang of DF-loaded station wagons would descend on us, loop antennas twirling, threatening to beat the both of us to marshmallow cream. The ham bands belong to all hams—says so right on the label.

This problem hasn't arisen until recently because, until recently, repeaters were something of a novelty. They were the new kids on the band, one here, one there, with lots of room in between and no objections from any of them to the ham who just wanted to jump in and say hello. Then the baby-boom babies grew up, bought Icoms, and started planting repeaters across the band like so many Johnny Appleseeds. We now have wall-to-wall repeaters, with more hams than all of them can handle. Hams, I've found, are incredibly courteous. If they find they're interfering with someone, they'll gladly slide up or down the band. But these days you can't take one step on 2 meters without stubbing your toe on somebody-or-other's repeater. Even more commonly, those repeaters are closed to the general hamming public. Do we have a problem? We sure do!

I now see the LA users'-rights crazies in an entirely new light. Out in the State of Excess, with more of everything per square inch than anywhere else, free space on the 2-meter band is probably pretty scarce. I have a hunch that the screamers are motivated by a feeling, just beneath the surface of rational expression, that the people who operate repeaters owe them something for the airspace that the repeaters take up.

In this new world of scarcity, nobody gets anything for nothing. We hams occupy our little sliver of God's good frequency spectrum because we provide free communication in times of national and international need. Have you forgotten that already? You shouldn't, because it's the only card we hold among the high rollers at WARC. A repeater cannot slide around the bands at will, the way that a man with a transceiver can. If a repeater effectively monopolizes a pair of frequencies, where's the justification?



At the present time, there isn't any. A repeater is an extension of a ham's private station, to do with as he pleases. My reading of the rules is pretty plain: A frequency pair is no man's own. If repeaters are to continue to sit on increasingly scarce frequencies, they must do what all the rest of us do for our country and our world—provide a service.

If a visiting ham slides into town and gets lost, he can key up a repeater and ask directions, right? Maybe, maybe not. If some drunk plows into him, he can key his HT and summon an ambulance on a repeater, right? Well, maybe. . .if he has the right PL. Otherwise, he'll just have to listen to the locals jaw about how soon they'll reach the work QTH while the drunk bleeds to death.

Rendering a worthwhile service may be no more complicated than keeping a repeater open to all incoming carriers, regardless of whether the incoming station is a club member, financial contributor, or somebody nobody has ever heard of.

I can already hear the gnashing teeth of repeater operators wondering how they'll support their machines if people aren't required to support them. Well, when I decided I wanted a transceiver, I saved my nickels and dimes until I got one. I did it because I *wanted* to. If a repeater club can't rake in enough voluntary support to keep its repeater running, maybe that repeater should be run in a less expensive location, or with reduced power, or without autopatch. Or maybe not at all. Does anyone else get the impression that there may be a few too many repeaters floating around?

Certainly, I see no justification at all for closed repeaters. They provide a service to only those few who are required to pay financial support, and still deny use of the frequency to licensed hams who do *not* want to use the repeater. This is a double violation of the rules that really ought to be looked at a little more closely. The users of repeaters have no rights to the machine, but they do have a right to an equal crack at the airspace. Or, perhaps, on the other hand, if the repeater keeps all rights to the frequency, then all hams deserve an equal crack at the machine. Does anyone agree? It's something we should talk about before we all become strangers on 2 meters, shouting vainly at repeaters which choose to hear only their favored few.■

My TRS-80 Is Here . . . Now What?

—first steps in programming your computer

Allan S. Joffe W3KBM
1005 Twining Road
Dresher PA 19025

You unpacked the large box, examined the contents, and carefully plugged it all together . . . and it works. By now, you have read the excellent book that comes with the TRS-80 or, if you are lucky enough to have Level II BASIC, then you had two books to read . . . and digest.

The nicest thing for any beginning programmer is no different from the nicest thing for the beginning ham: a starting point to get from the superregenerative receiver to the superheterodyne. Both problems relate in this fashion. A complex radio is really nothing more than a collection of properly associated simple circuits which make up the whole. A whipper-doodingbust-golly-gee computer program is more of the same. The trick is to grab a firm hold of the elements from a simple starting point.

For purposes of illustration, I have chosen to work over a nice program in the TRS-80 level I BASIC book which sets forth a 24-hour clock program.

Taken verbatim from the book:

```
10 CLS
20 PRINT AT 407, " H M S "
30 FOR H = 0 TO 23
40 FOR M = 0 TO 59
50 FOR S = 0 TO 59
60 PRINT AT 470, H; ":" ;M; ":" ;S
70 FOR N= 1 TO 500: NEXT N
80 NEXT S
90 NEXT M
100 NEXT H
```

When entering this program and running it, you see the hours, minutes, and seconds start to count from 0:0:0.

With this much as our starting point, we can operate upon the basic program a bit at a time, so we do not byte off so much that we eschew it.

Like any sensible person, if you bought a timepiece at the local emporium, got it home and found you had no way to set the time, you could rightly work up a bit of indignation. Well, this clock so far is in that fix, but you can program it into practicality with the following few steps. Remember, we are listing new or revised lines to the fundamental program as we go.

```
52 X=X +1
54 IF X = 1 THEN 110
72 CLS
105 GOTO 30
110 INPUT H,M,S
120 GOTO 60
```

Now if you enter the program and run it, a header will appear as before, but this time there will be a "?" showing along with the header. The computer is saying, tell me what time you want me to start counting from. You enter the requested information by typing 3,0,0, which could be three am or three pm, depending on your life-style. Now when you hit ENTER, the clock starts keeping time from the entered data. You have added a knob to "set the hands."

What the whole process really amounts to is educational self-help. Working a bit at a time to alter programs means you will master the skill of programming. After all, you did not buy the machine to use someone's canned programs for the sheer thrill of getting typing practice.

So much for the philosophy. How about another small change? This time, let's humanize the program by changing it from a 24-hour clock to the usual 12-hour variety. This takes one more change to the program. Line 30 now becomes:

```
30 FOR H = 1 TO 12
```

You probably are not too happy with that vertical string of zeroes in the original program or any stray

 Dec 1979

zero on the left side of the screen. We can de-zero the display by changing the contents of two lines in the program, namely lines 20 and 60. They now become:

```
20 PRINT "H M S"
60 PRINT H ; ":" ;M; ":" ; S
```

Now that we have de-zeroed the display, just a word about clock accuracy. The book suggests the number 500 in the timing loop in line 70. With the particular machine I had before me, 300 seemed to give a country-fair minute.

So far, we have a rather conventional clock which, without too much effort, can be turned into a conventional down-counting timer. With these changes, you have a timer that starts from a predetermined starting time of your choice, starts counting at the push of a button, and stops counting when it reaches zero.

These are the program changes to make the timer:

```
30 FOR H = 11 TO 0 STEP -1
40 FOR M = 59 TO 0 STEP -1
50 FOR S = 59 TO 0 STEP -1
105 END
```

The first three lines shown here reverse the order of counting from up, as needed for the regular clock, to down as desired for the advertised down-counter. The final change (line 105) makes the counter stop when the count has wound down to zero.

Small programs like this may not have the oomph of Lunar Lander or Star Trek but they lend themselves to piece-by-piece manipulation on a somewhat intuitive basis. (Reading the books that came with your computer also helps.) This is one way to achieve familiarity with the programming language that you must master if your computer is going to be more than a large, expensive paperweight. ■

Teaching Your Micro to Count

—two methods for adding counter capability to your 6502 machine

Sam Creason K6EW
2940 Arlington Ave.
Fullerton CA 92635

One of the handier pieces of test equipment for digital circuits is a counter. If it's used to troubleshoot or design systems which involve a microprocessor (μP), it need not be expensive, since it need not count at a rate faster than a few MHz. Then, too, if it's used with an already-existing μP system, it is simple to construct, since the μP system can replace some of the hard-wired logic that is normally required.

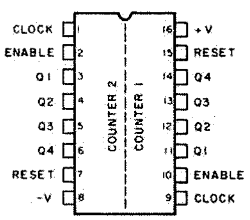


Fig. 1. Pin connections of 4518 dual BCD counter.

In the context of a μP system, we can implement a counter in more than one way. The first is straightforward, involving ICs which do the counting. The second way is also straightforward, but rather unconventional. The implementation consists almost entirely of a program, and we need add little or no hardware at all to our system. By comparing the two implementations, we can learn a little about replacing hardware with software and see what trade-off is involved. Our primary goal, though, is simply to add a useful piece of equipment to our system. As we'll see later, the conventional implementation produces a more versatile counter, so we'll consider it first.

Q_4	Q_3	Q_2	Q_1
0	0	0	0
0	0	0	1
0	0	1	0
0	0	1	1
0	1	0	0
0	1	0	1
0	1	1	0
0	1	1	1
1	0	0	0
1	0	0	1

Fig. 2. Response of counter to square wave.

The Counter IC

The principal component of our first counter is the 4518 dual BCD counter. Its pin connections are shown in Fig. 1. As its name implies, there are two independent BCD counters within the IC. There is no particular significance to the designations "1" and "2" in the figure.

Each counter has a RESET input. Applying a high level to this input forces outputs Q_1, Q_2, Q_3, and Q_4 to 0. Applying a high level to the ENABLE input and a low-to-high transition to the CLOCK input then advances the count from $Q_4Q_3Q_2Q_1$ = 0000 to $Q_4Q_3Q_2Q_1$=0001. As long as we hold the ENABLE input high, each successive low-to-high transition advances the count by one until a count of nine (1001) is reached. The next transition returns the count to 0000. Similarly, if we hold the CLOCK input low and apply a high-to-low transition to the ENABLE input, the count will advance.

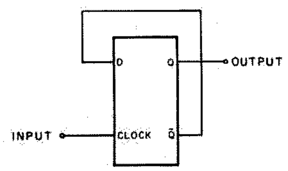

Fig. 3. Conditioning circuit.

If we want to determine the fundamental frequency of a square wave, and we know that it's between one and nine Hz, we can make at least an approximate measurement by applying the square wave to the ENABLE input and carrying out the following sequence of operations:

1. Take CLOCK input high.
2. Reset counter.
3. Take CLOCK input low for one second.
4. Take CLOCK input high.

At the end of this sequence, the count is numerically equal to the frequency of the square wave in Hz, give or take a Hz.

Alternatively, we could accomplish the same thing by applying the square wave to the CLOCK input, taking the ENABLE input low, resetting the counters, and taking the ENABLE input high for one second.

A Multi-Digit Counter

To make useful measurements, we very often need a counter which can count beyond nine. For this, we can use the output of one counter to drive an input of a second counter, and so on. Since the digital display of my system has six digits, I used a total of six counters (three 4518s).

Although the waveform which we want to measure can be applied to either the CLOCK or the ENABLE input of the first counter, we have to be careful about the way in which we interconnect the remaining counters. As successive cycles of the waveform toggle the first counter, the outputs of that counter change as shown in Fig. 2. Each time the count changes from 9 to 0, the next counter should be toggled once. That is, as the count in a particular counter goes from 9 to 0, that counter should generate a carry for the next counter. For this purpose, we can use the Q_4 output of the counter. As the count goes from 9 to 0, that output makes a high-to-low transition. Thus, we need only tie the Q_4 output of the first counter to the ENABLE input of the second counter, and tie the CLOCK input of the second counter permanently low. We can add as many more counters as we like, in a similar way.

Measuring a Frequency—The Timebase

At this point we have a multi-digit counter, but we need a way to enable or disable counters so that we know how much time was spent accumulating a particular count. That is, we need a timebase. A ½-Hz square wave is a reasonable choice, since it's high for one second, low for one second, and so on. If we apply such a square wave to the CLOCK input of the first counter and apply the waveform which we want to measure to the ENABLE input, the first counter will count for one second, stop counting for one second, and so on. Since the first counter won't generate carries when it's not counting, the five remaining counters will count and stop also. To make a measurement, we let the counters count for one second and then process and display the count during the next second.

If we use a ½-Hz square wave as a timebase, the count which is accumulated during one counting period is numerically equal to the frequency in Hz of the unknown waveform. Since our counter has six digits, 999,999 Hz is the highest frequency which it can measure under these conditions. We can extend that range by a factor of ten if we use a 5-Hz square wave as a timebase, since such a square wave is low for only a tenth of a second at a time. During that time, a 9.99999-MHz waveform will produce a count of 999999, which our display can accommodate. In this case, the count is numerically equal to the frequency in Hz/10.

Since the CMOS counters which we'll use can't be toggled faster than about 2-3 MHz (when a 5-volt power supply is used), we have no immediate need for a timebase which is higher in frequency than 5 Hz.

At this point, then, we have in hand the necessary ingredients to make measurements of frequency. Before we turn our attention to the hardware itself, however, let's consider one additional topic.

Measuring a Period

We've seen that measuring a relatively high-frequency waveform isn't all that difficult, but what if the unknown waveform has a frequency of, say, 10 Hz? If we use a ½-Hz square wave as the timebase, then 10 counts will be accumulated at a time, and our measurement will be accurate to only one part in ten. For many purposes, that's adequate. However, if we want to count long enough to take full advantage of our counter, we'll have to use a 1/20000-Hz square wave as the timebase. Of course, that means that the counter will count for about five and one-half hours at a time!

There is a better way, and it involves using the unknown waveform as the timebase while the counter counts cycles of a waveform for which the frequency is known. For example, if the known frequency is 1 MHz, and a count of, say, 97,350 accumulates during one "on period" while using the unknown waveform as the timebase, then the "on period" is 97,350 micro-

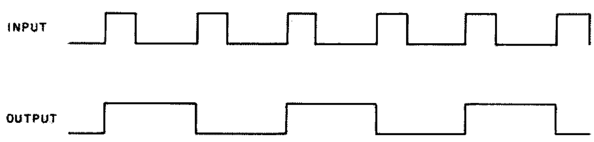

Fig. 4. Effect of conditioning circuit.

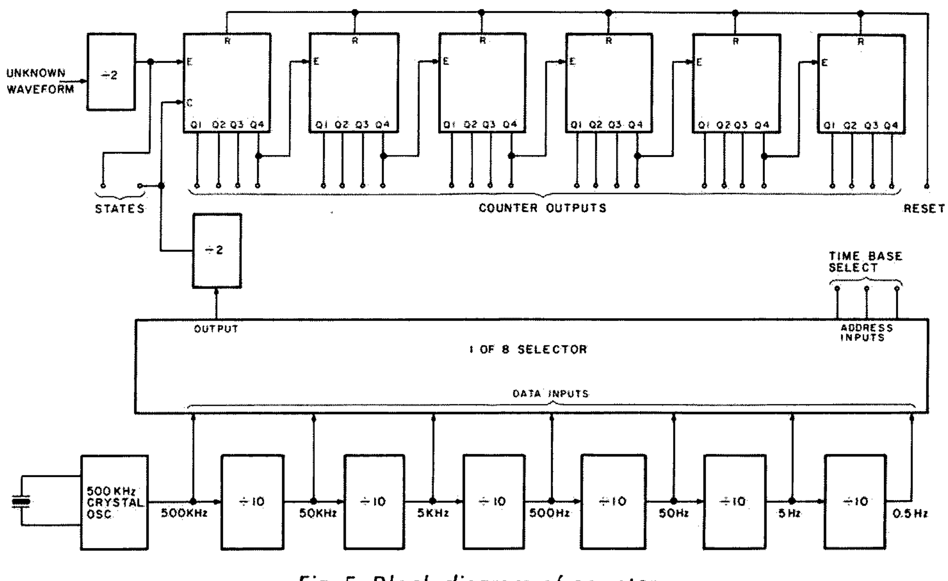

Fig. 5. Block diagram of counter.

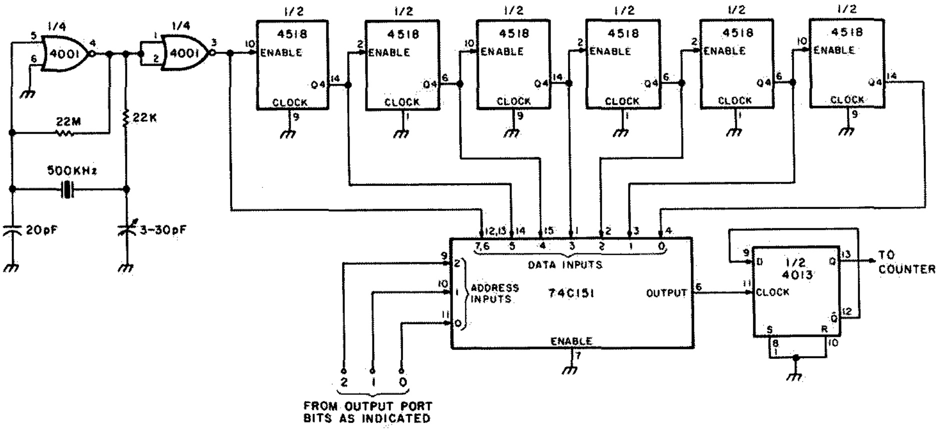

Fig. 6. Timebase for counter. Note: Ground reset terminals of 4518s (pins 7 and 15).

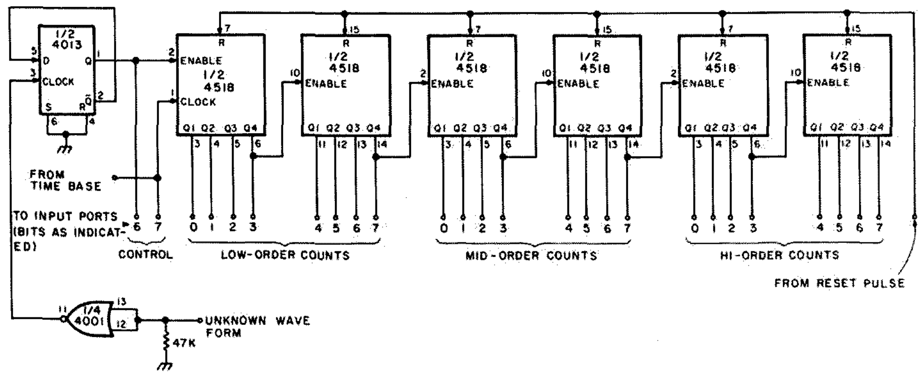

Fig. 7. The counters. Note: Unless otherwise specified, ground clock terminals of 4518s (pins 1 and 9).

seconds. (The duration of one cycle of a 1-MHz waveform is one microsecond.) Since 97,350 microseconds is 0.097350 seconds, the unknown waveform must have been high for 0.097350 seconds. Assuming that it's low for the same amount of time that it's high, then the period of one cycle of the waveform is two times 0.097350, or 0.19470 seconds. Thus, its frequency is 1/0.1947, or 5.1361 Hz. By using the modified technique, we've made a measurement which is quite accurate, and done so in less than a second.

Two problems remain, however. First, this technique measures the time during which the unknown waveform is high. However, not all waveforms are high for the same amount of time that they're low. That is, not all waveforms have a 50% duty cycle. The problem is that unless we know the percent duty cycle of such a waveform, we can't make an accurate measurement of its period. A solution to the problem is to apply the unknown waveform to the circuit which is shown in Fig. 3.

The unknown waveform is applied to the CLOCK input of a type D flip-flop. Thus, each time the waveform undergoes a low-to-high transition, it triggers the flip-flop. This transfers to the $\overline{Q}$ output whatever level is present at the D input when the transition occurs. Thus, since the $\overline{Q}$ output is applied to the D input, the Q output will change state in response to each transition. This behavior is summarized in Fig. 4.

What's important for our purpose is that we have a waveform which is high for one period of the unknown waveform, low for the same amount of time, and so on. That is, the derived waveform has a 50% duty cycle and we can measure its period easily.

The second problem which remains is one that we won't consider further at this time. It's simply that once we've measured the period of a waveform, we must compute the reciprocal of that number in order to determine the frequency of the waveform. Those with a floating-point package in the software of their system will have no problem doing this.

Finally, we should note that the circuit in Fig. 3 produces only one high-to-low transition at its output for every two low-to-high transitions at its input. In effect, it divides the unknown frequency by two. Thus, if we make the circuit a permanent part of our counter, we must take this into account. An easy way to do this is to halve the frequency of the conventional timebase so that the timebase is high for two (or 0.2) seconds and low for the same amount of time.

A Block Diagram

At this point, we can rough out a block diagram of at least part of our counter, as shown in Fig. 5.

The unknown waveform is applied to a divide-by-two circuit which, in turn, drives the first of six BCD counters (each is half of a 4018). A 500-kHz crystal oscillator generates the timebase. It drives the first of six BCD counters (each is half of a 4018). Since each counter counts to nine and generates a carry, we can view each as a divide-by-ten circuit as well as a counter.

The lowest available frequency which is available from the timebase is 0.5 Hz. A little arithmetic will show that, in this case, that value will produce a count which is numerically equal to half the frequency in Hz of the waveform—but we'll soon remedy that. A one-of-eight selector passes the selected timebase on to the input of a divide-by-two circuit. In turn, that circuit drives the CLOCK input of the first counter, and our problem is remedied.

We could use a 250-kHz crystal and dispense with the divide-by-two circuit, but 500-kHz crystals are less expensive, and the flip-flop IC which we'll use (4013) contains two flip-flops.

The Interface

To interface the counter to a µP system, we need four input ports and an output port. In addition, we need a pulse which is similar to a

WRITE pulse, to reset the counters. Such a pulse can be generated by using one line of a second output port. Writing 0-1-0 onto the line produces a positive-going pulse.

Three of the input ports are used to read the contents of the counters. The fourth is used to monitor the states of the CLOCK and ENABLE inputs of the first counter. Depending on which counting technique is used (frequency or period), the state of one or the other of the inputs indicates whether or not the counters are counting.

The output port is used to apply a number to the address inputs of the one-of-eight selector, to choose the timebase.

The Timebase

The circuit of the timebase is shown in Fig. 6.

Two gates from a 4001 quad two-input NOR IC, a 500-kHz crystal, and a few passive components make up the timebase generator. The output of the oscillator drives a chain of three 4518 dual BCD counter ICs. The outputs of the six counters are applied to the DATA inputs of a 74C151 one-of-eight selector. Depending on the number which is applied to the ADDRESS inputs of the 74C151, a particular timebase is passed on to the counters via a divide-by-two circuit.

The Counter

The circuit of the counters is shown in Fig. 7. The unknown waveform is applied to the input of a 4001 NOR gate which acts as a buffer. (Good practice dictates that lines which originate off the board should not be connected directly to the CLOCK input of a flip-flop, in the interest of immunity to noise.) The NOR gate drives half of a 4013 type-D flip-flop IC which is configured as a divide-by-two circuit. The output of that circuit drives the ENABLE input of the first of a chain of three 4518 dual BCD counters.

Using the Counter With the BMPS

The counter was originally designed for use with a beginner's microprocessor system based on the 6502 μP. That system is described in detail elsewhere.[1] Those who have built such a system may use the counter by adding the interface which is shown in Fig. 8. (Of course, the interface is not needed if the builder has expanded the basic BMPS to provide additional I/O parts.) Those who will use the counter with other than the basic BMPS should ignore the next two paragraphs.

A circuit which provides the necessary control signals is shown in Fig. 8(a). It consists of a 4514 decoder, a 4011 quad two-input NAND gate, and a 4081 quad two-input AND gate. Address lines A_0, A_1, A_2, A_{14}, and A_{15} are applied to the inputs of the 4514. Four READ signals are generated by ANDing the R/W line with outputs of the 4514. Two pulses are generated by NANDing the ϕ_2 line with other outputs of the 4514. One of these is a WRITE pulse of the sort which we've used before. The remaining pulse is complemented and used to reset the counters. When we want to reset the counters, we use a STA, STX, or STY instruction in the program. No port exists which will accept the operand of the instruction, but the pulse is generated. The address of each READ and WRITE signal is as shown in Fig. 8(a).

A circuit which provides the I/O ports is shown in Fig. 8(b). A latch (4042) and solid-state switches (4016) are used as described in Reference 1.

Construction

The foil side of the PC board and the component layout are shown in Figs. 9 and 10, respectively. Those who will not use the counter with the basic BMPS may prefer a more compact layout which does not include the unnecessary portion of the I/O circuit.

The timebase should be checked out first. If the oscillator does not start reliably when power is applied, the values of one or more passive components should be varied slightly. With the oscillator working, we then check the 74C151 selector. Writing a number from 000 through 111 to its address inputs should tie the output of the selector to the designated one of its seven inputs. We then add the 4518s to complete the timebase. When that's done, writing a 000 to the address inputs should produce a 0.25-Hz square wave at the output of the 4013. That frequency is low enough to be observed with a logic probe.

When the timebase is working properly, we can use it to check the counter ICs. To do this, we temporarily remove the 4013 from its socket. We then

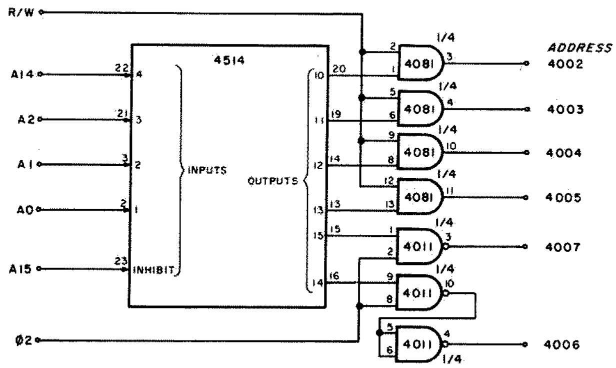

Fig. 8(a). Partial schematic of interface to BMPS.

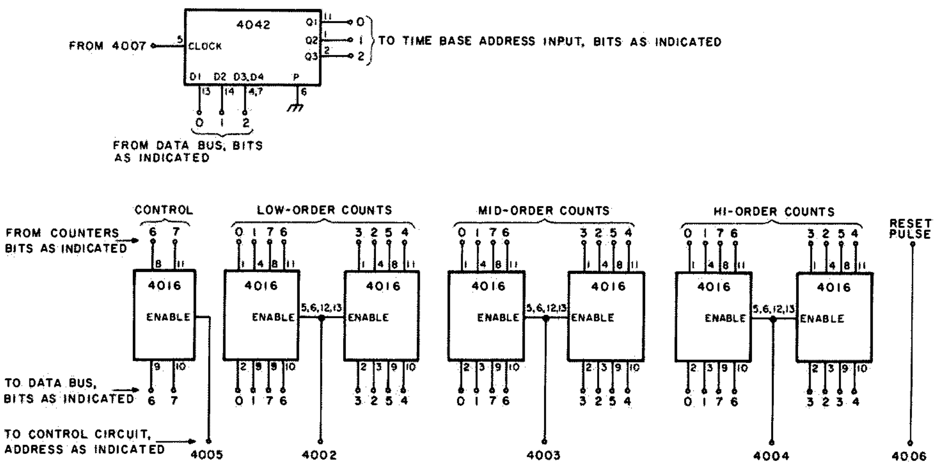

Fig. 8(b). Partial schematic of interface to BMPS.

connect the output of the timebase to the ENABLE input of the first counter and ground the CLOCK input of that same counter. The net result is that the timebase toggles the chain of six counters. Those using

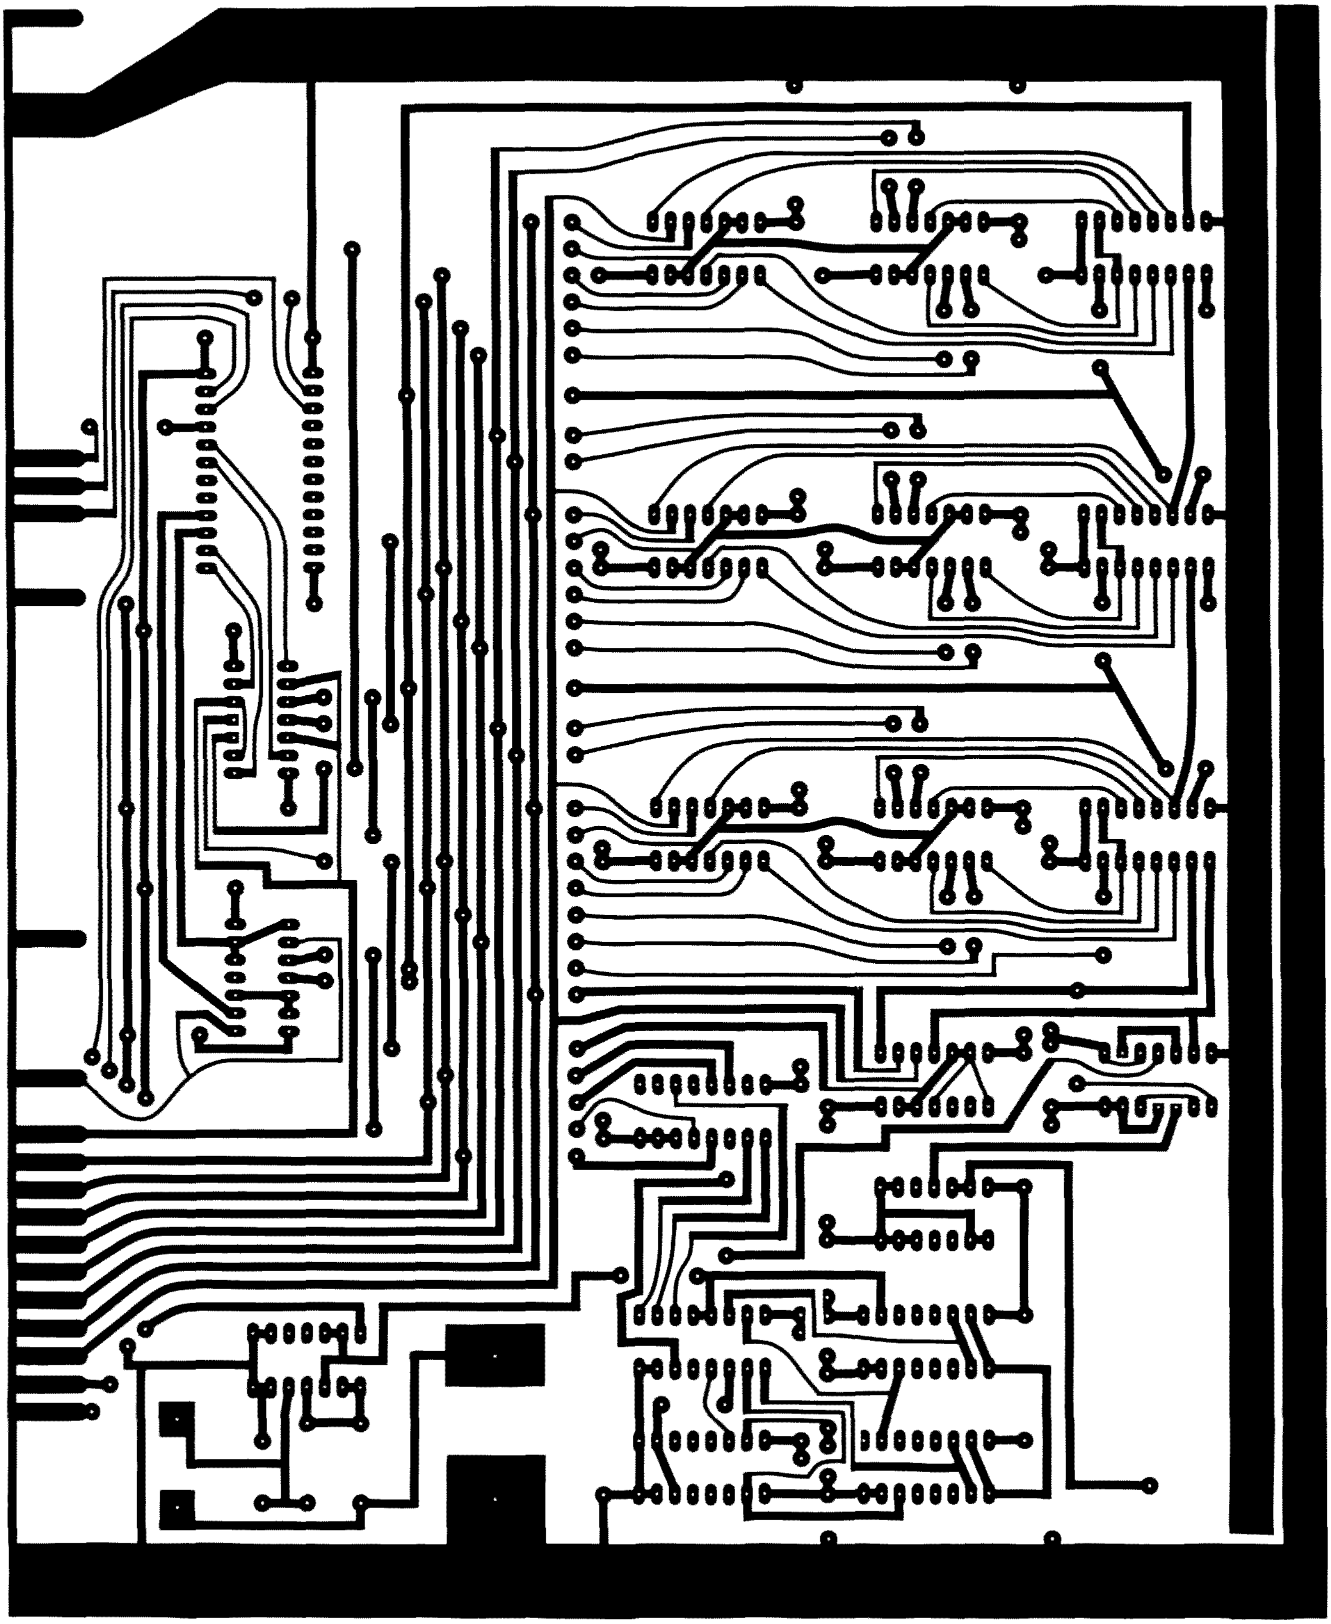

Fig. 9. Foil side of printed circuit board for counter. Install crystal socket on this side. Install a 0.1 μF disc ceramic capacitor across power pins of each 45189 and 4013.

the basic BMPS should load the program which is shown in Fig. 11 and monitor output port 8200. In this way, the outputs of any one of the pairs of counters can be observed. Others can check the outputs of the counters with a logic probe. Finally, we restore the 4013 and disconnect all temporary connections.

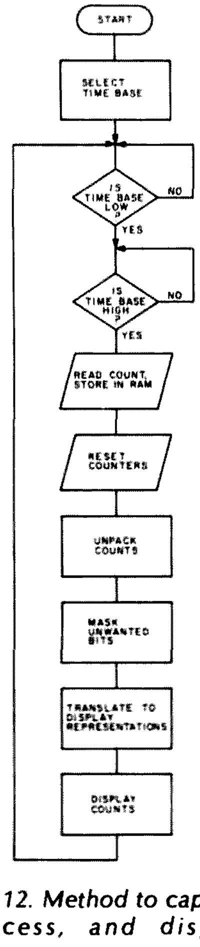

Fig. 12. Method to capture, process, and display counts.

A Counter Program

At this point, the hardware is complete and checked out. We can select the frequency of the timebase, read the outputs of the counters, and reset the counters. We'll now examine a program which will perform these functions in the proper sequence to produce a useful counter. A block diagram is shown in Fig. 12.

The first step is selection of a timebase. Nothing of significance happens then until the output of the timebase is first low (counters counting) and then high (counters not counting). We then read and reset the counters. Once this happens, we have in memory three eight-bit numbers which represent the counts that were accumulated by the six counters. Each eight-bit number consists of a pair of BCD numbers "side by side." Accordingly, the next order of business is to "unpack" the numbers so that each BCD number is in the four lower-order bits of its own individual location in memory. We then reset to 0 the four higher-order bits (unused) of each word, translate the BCD numbers into the correct representations for the digital display, and display the results. The entire process is then repeated.

A program which will do what we've been talking about is shown in Fig. 13. It's written for the BMPS, but since I/O address assignments are given, modifying it for any 6502 system should be no problem.

The operator must load into location FFFF the number which represents the desired timebase. (Only the three lower-order bits are used.) The instructions which lie between FF80 and FF8F read the number in location FFFF, store it in the 4042 latch (thus selecting the timebase) and delay further execution of the program until the timebase has gone low and then high.

When the timebase has gone high, a count has been accumulated and the counters have stopped counting. Accordingly, the instructions which lie between FF90 and FF9C read the counters, store the results in locations 0002, 0001 and 0000, and reset the counters in anticipation of the next count. At this point, the counts are stored as shown in Fig. 14(a), and they must be transformed for display as shown in Fig. 14(b).

The first step in the process is to unpack the BCD digits. The instructions which lie between FFA0 and FFB5 accomplish this. The XR and YR are each set to 0. A 0000-based, YR-indexed LDA and a 0003-based, XR-indexed STA are then performed. The contents of the ACR are shifted right four places, the XR is incremented, and a 0003-based, XR-indexed STA is performed. At this point, the least-significant count (in the form of a BCD number between 0 and 9) occupies the four less-significant bits of location 0003. The next more-significant count occupies a similar position in location 0004. Of course, the next more-significant count also occupies the four more higher bits of location 0003 as well, but this is of no consequence. After three traverses of the loop, the counts occupy the locations which are shown in Fig. 14(c).

The instructions which lie between FFB9 and FFCE accomplish what remains: to display the counts. The XR is set to 5 in order to process six counts. An 0003-based, XR-indexed LDA is accomplished, and 0F is ANDed with the contents of the ACR. This sets the four more-significant bits of the number to 0, so that only the desired count remains. The next instruction, TAY, transfers the count to the YR. An FFD0-based, YR-indexed LDA is performed. Since the seven-segment representations of the numbers from 0-9 are stored starting at location FFD0, this places the representation of the count in the ACR.

The final step is to store the representation in the appropriate display element. Since the addresses of the display elements don't fall in the same order as the addresses of the source locations, we use a somewhat roundabout method to accomplish this. An FFDA-based, XR-indexed LDY is performed. This places in the YR the least-significant hexadecimal digit of the address of the appropriate display element. Performing an 8000-based, YR-indexed STA then accomplishes what we desire.

Fig. 13. Program to implement counter. Note: In FFF0, X = 3, 4, 5, 6, 7, or 8, depending on which register is to be examined. In FFFF, X = 1, 2, 3, 4, 5, 6, or 7, depending on which timebase is to be used.

Fig. 14(b). Destination of counts.

Traversing the loop six times stores all six counts.

The remaining instructions (CLC, BCC) cause the program to branch to location FF86, and the process starts again. To change the timebase requires a reset.

The NOP instructions which are located in FF9D-FF9F and FFB6-FFB8 serve no useful purpose and may be omitted. (Change the operand of the BRANCH instruction at FFCD, if done.) However, if either set is replaced with JMP FFF0, the short program which starts at FFF0 will store a selected pair of counts into the output port which is located at 8200. This is convenient when checking out the program.

Finally, if measurements of period rather than frequency are to be made, ASL instructions should be inserted between LOOK1 LDA 4005 and BMI LOOK1, and between LOOK2 LDA 4005 and BPL LOOK2, so that the proper bit is examined. Then, too, BMI LOOK1 should be changed to BPL LOOK1, changed to BMI LOOK2, to take into account the difference in the way the bits must be interpreted.

Fig. 16. Program to implement a counter in software. Note: In FFB2, X = 0, 1, or 2, depending on which register is to be examined.

Doing It the Easy Way

The counter which we've just discussed is a useful and versatile addition to almost any system. However, if we can tolerate a limitation in speed, then we can have a counter just by using the system itself, provided it has a timer and a digital display. We can write a program to simulate the action of a counter. The basic principle involves using the timer as a timebase and counting the number of high-to-low (or low-to-high) transitions which the unknown waveform makes while the timer is "on." What's involved in the context of the BMPS is shown in Fig. 15. Using the technique with other systems should be straightforward.

The first step is to set the 6502 μP to the decimal mode. This means that in any operation which in-

volves an ADC or SBC instruction, the μP treats the eight-bit numbers which are involved as pairs of BCD digits. The next step is to clear the carry bit and three locations (registers) in the RAM. We designate the locations as LO, MID, and HI to indicate which pair of counts each holds.

We begin counting by starting the timer. We then check to see if the unknown waveform is low. If so, we add 1 to LO, 0 to MID, and 0 to HI. (Adding 0 to a number adds the carry, if any, from the next less-significant count.) If the output of the timer is still high by this time, we wait until the unknown waveform goes high and then low, and again modify the registers as appropriate. The process is repeated again and again until the output of the timer goes low. At that time, we process the counts in exactly the same way as if they had come from the counter board.

Only a few connections to the BMPS are necessary in order to implement the counter. The WRITE pulse for the output port at location 8100 is used to start the timer, while the most-significant bit of the input port at location A000 is used to monitor the output of the timer. The unknown waveform is tied to the most-significant bit of the input port at location 9000.

A program which will provide the function of a counter is shown in Fig. 16. Little comment is necessary, since it closely follows the flowchart.

The instructions which lie between FF80 and FFB1 in this program perform essentially the same function as the instructions which lie between FF86 and FF9C in the previous program. In each case, the counts are stored in locations 0000, 0001, and 0002. Thus, the portion of the previous program which processes and displays the counts clearly should be usable with this program, although I've not tried it. The instructions which lie between FFB2 and FFB9 in the present program provide a simple way to examine the contents of any of the registers. All that's necessary is to monitor the output port at location 8200.

Once we've implemented the counter in this way, all we need do further is to adjust the period of the timer until it's some convenient value, such as 1 second.

The price we pay for doing it the easy way—substituting software for hardware—is a loss of speed. In this case, the time between low-to-high transitions of the unknown waveform must be longer than the time which is required for the μP to traverse the inner loop of the program. This means that the frequency of the unknown waveform must be less than a few kilohertz.

A Preamplifier

Either counter is directly usable as is on CMOS-compatible signals. Those who will use the counter on other types of signals should add a signal-conditioning preamplifier of the sort shown in Reference 2 (substitute a 4049 CMOS hex inverter for the 7404, for example). There is room at the upper left corner of the PC board to do this. ■

Operation Santa!

—spread holiday cheer with this super club project

Photos by K8ZIS and W8WN

Photo A. Even without the red suit and long, white beard, Dave W8IFK looks and sounds like Santa.

"Santa's on television and wants to talk to you!"

How could that be? Well, once again old Santa made an appearance for the kids at McLaren Hospital in Flint, Michigan, to try to cheer up those who would be confined to the hospital over the holidays. Nothing unusual about that? This electronic Santa came to them via radio, color television, and (it is reported, perhaps with some imagination) via a multiple relay of stations all the way from the North Pole.

Santa has been coming to hospitals for many, many years, and amateurs have been able to let the kids in other hospitals talk to Santa "way off at the North Pole" via amateur radio for more years than most of us can remember. But a year ago, McLaren Hospital, in Flint, apparently was one of the first hospitals in the nation to go one step further. It initiated the practice of having Santa also appear on the in-house color TV system so that the kids (and anyone else in the hospital who wished to tune in) could not only hear the old gent, but also could see him in living color as he replied to their questions and requests.

"Operation Santa" for 1978 began as WD8KQI (Dr. Dan Bonbrisco, D.O.) and a couple of other members of the Genesee County Amateur Radio Emergency Service let the kids at the Flint Osteopathic Hospital talk with Santa via the 147.87/.27 Flint Hainer repeater. Meanwhile, Santa, also known as W8IFK, was across the street at McLaren Hospital trying to talk with the kids and get into his Santa suit at the same time.

After everyone in the pediatric ward at FOH had talked with the resident of the North Pole, the telephone operator at McLaren announced over the PA system that Santa would be on a certain TV channel in a few minutes to talk to the children there. Color bars were punched up, amateurs and hospital technicians made sure the TV sets in the pediatric sections were

tuned and working properly, and all the children who could walk or be moved were taken to the sun rooms.

When all was ready, W8UPV put out a call over the Hainer repeater for Santa Claus. He didn't get him, but he did get another amateur "near Greenland" who said he could relay the traffic. Two more relays, including one "from an amateur at a DEW line radar post," got them close to the North Pole, but Santa didn't seem to be available. An autopatch, though, brought an answer from Santa's private secretary, who said that Santa was in his workshop but would be arriving momentarily. Meanwhile, slides of various operators at their shacks, the OSCAR satellites, etc., were being shown on the TV screen.

The screen suddenly went to color bars again (to allow the camera to be pivoted 180° in a very crowded photographic studio there in the hospital), and then came alive and focused on a large chair in front of a deep blue background just as a jolly, white-haired fellow, carrying a TR-22 and an extra mike, came in and sat down. Santa had arrived, and he said he wanted to talk with boys and girls in the hospital there in Flint, Michigan!

After a few minutes of getting himself composed, while describing the work he had been doing in the workshop, Santa asked to talk to the first little boy. But before the first one had even said anything over the mike of the HT down in the sun room, Santa had already called him by name and said he was sorry he had to be in the hospital; he even named the exact illness the boy had!

This was very mystifying—how could Santa know who was going to talk first? The same thing happened with all the other children—Santa knew names, illnesses, ages, and sometimes other facts about each one of them. One little boy became very excited. It seems that he had talked with "Santa" in one of the stores a couple of weeks earlier and had given him his name. "He remembered me!" the boy shouted, causing a great deal of merriment among the hams and nurses.

Since the children were busy watching the child who was talking and watching the TV screen to see Santa as he replied, most did not notice the other amateurs in the back of the room getting advance information on the next child and relaying it via .52 simplex to the photographic studio upstairs. Neither could they see the large chalkboard, just behind the TV camera, where names, ages, and illnesses were being written down (next to a permanent list of Santa's reindeer team, without which old Santa seemed to experience his one memory lapse).

Did you ever wonder just how Santa can listen to the requests kids make and give an answer that satisfies them without putting too much pressure on parents? This is a talent in itself. The requests run from the simplest, a doll, to the more expensive and elaborate, such as a real racing car or a diamond ring. Santa would laugh and compliment the child on his wanting reasonable things (if that were the case), or on how big his ideas were (for some of the more unreasonable ones). He would admonish them to be good, tell them that he would see what he could do, and that he thought he could find something that they would like (while never saying that he would give them what they actually asked for).

Many children, of course, just wanted to get out of the hospital in time for Christmas. For these, Santa had especially kind words, also reminding them to follow the doctor's instructions. One teenage boy was especially depressed—he had just broken both legs while skiing. While his injuries were not really serious, it was a bleak holiday season for that young fellow.

After talking with all the children in each of the sun rooms, the operators visited the rooms of the children who could not join the group. Invariably, they came upon nurses who were watching the TV screen but could not leave to see what was actually happening. Often they surprised the nurses with the opportunity to talk with Santa (much to the delight of Santa!), and he would then proceed to identify them and talk with them, also to the delight of the

Photo B. "Santa" (W8IFK) talks to the kids via his TR-22 and the in-house color TV system while WA8IUS mans the camera. Note the second mike cord going under Santa's beard.

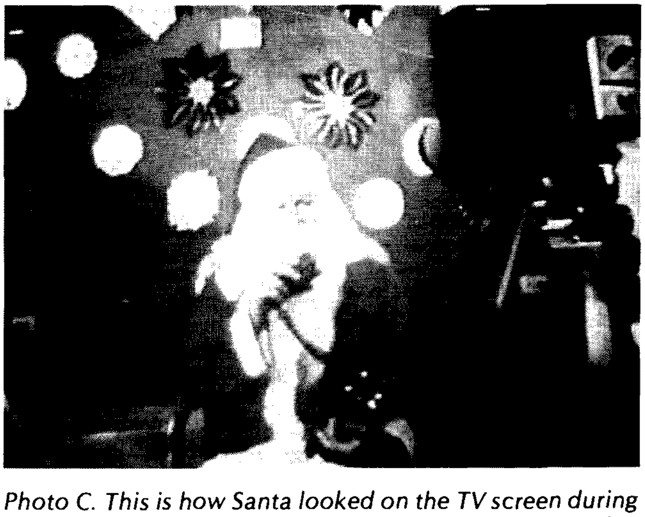

Photo C. This is how Santa looked on the TV screen during a newscast which gave a little extra PR for amateur radio.

children, doctors, nurses and all who were watching.

After talking with all the children (and some of the nurses) in McLaren, as the TV operation was being closed down, Santa talked with the grandchildren of several amateurs who had been monitoring. A news photographer from one of the local TV stations had arrived and filmed the scene in one of the sun rooms, so "Santa" had to get set again while a little newsreel footage was filmed.

"Operation Santa" had been done several times in Flint in the past, but in 1977, K8ZIS, medical photographer at McLaren Hospital, suggested that it be put on the newly-installed in-house TV system. Apparently, two other hospitals in other parts of the country also had the same idea at about the same time, and this has provided much pleasure for the children in those hospitals. But not only for the children—it has been noted that the adult patients, nurses, and doctors seem to enjoy watching the show as much as the kids themselves. It was not unusual to find sun rooms and wards all over the hospital crowded with patients, nurses, and interns watching their local "Operation Santa" on their own TV channel.

The Genesee County ARES provides emergency communications for the seven area hospitals as well as for a number of other groups. "Operation Santa" is hardly an emergency, but it is one of those little public service events that brings pleasure to someone else while improving our public relations. With the closed-circuit TV system, amateur radio is even more visible than ever.

Photo D. Santa's "memory" of the names of children was updated on this off-camera blackboard.

Operators who took part in the 1978 "Operation Santa" in Flint were W8IFK (who makes a magnificent Santa, even without the bright red suit), K8ZIS (medical photographer at McLaren who originated the TV idea locally), W8UPV, WD8JCN, WD8KQI WA8IUS, K8XN, W8YCN, WD8LMP, WD8CCG, and WA8ZQM. The operation was sponsored by the Genesee County Amateur Radio Emergency Service, Inc., the Hainer Repeater Association, and McLaren Hospital.■

Tools and Techniques for Wire-Wrapping

—an excerpt from 73's new book

Editor's note: This article is an excerpt from 73's new book, *Tools and Techniques for Electronics*, by A. A. Wicks W6SWZ. The book is a comprehensive guide to construction practices, from soldering to PC boards to metalworking. It's available from 73's Radio Bookshop, Peterborough NH 03458. The price is $4.95 (plus $1.00 tor shipping and handling).

As experimenters and hobbyists become more and more involved in integrated circuitry and equipment that utilizes these and other miniature devices, a technique that has been used in industry for many years becomes attractive to use. Although originally developed in the early 1950s, a solderless interconnection technique known as wire-wrapping did not immediately gain popularity within industry until automatic and semiautomatic wire-wrapping equipment, for the most part using programmed tape equipment, provided a low-cost, rapid method of making thousands of these solderless connections on the "back panel" of component boards.

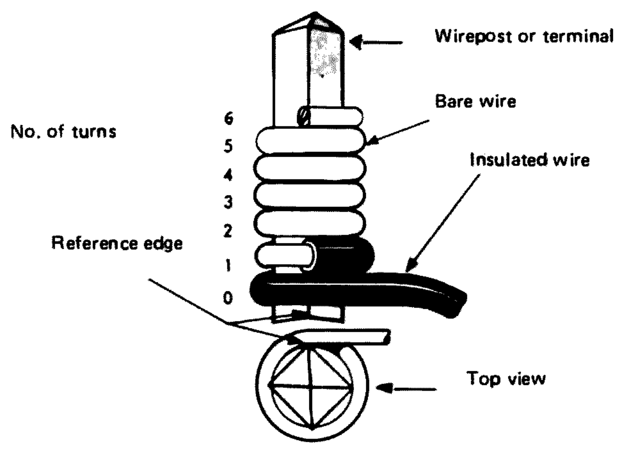

Fig. 1. Wire-wrapped terminal and references.

A wire-wrapped connection is shown in Fig. 1. It is exactly that—a wire, "wrapped" around a terminal post several turns, which provides an absolute metal-to-metal, gastight connection. At first, these connections were made by using a hand-operated tool. Then, speed was gained by driving this tool with an electric motor in the form of a "gun" in which the tool was inserted and locked. This technique continued to be used industrially, even with the advent of programmed machinery which, point-by-point, moved the electric tool over a back panel, at which point a human operator inserted a pre-cut and pre-stripped length of wire in the tool, lowered it over the wire terminal post, made the wrap, then allowed the tool to move to its next location. This technique continues to be used today, but in more sophisticated applications of mass production, the whole operation is programmed and automatic.

While this was going on, the engineering laboratories were involved in prototype production, but, as is obvious, prototypes do not warrant the expense of specialized programmed equipment worth tens of thousands of dollars.

Therefore, back in the lab, engineers and technicians continue to use hand wire-wrapping tools, both manual and electric. And it is to this level, the prototype level, that we, as experimenters and hobby work-

ers, direct our interest.

The techniques of wire-wrapping are especially desirable in place of printed circuit boards (frequently called "cards"), when only one unit is to be produced. Printed circuit layout and preparation for one assembly, although creative fun and very effective, is more work than enjoyment in many instances, especially for the person anxious to have a circuit completed and ready for operation quickly. (A combination of printed circuit and wire-wrapping will be discussed later in this section.)

The information provided here is directed for the most part to those who have never performed wire-wrapping. A person already involved in this type of construction is usually extremely enthusiastic about its time-saving and "second-chance" possibilities (a printed circuit is *very* difficult to change, once etched). Before proceeding, we should mention some of the terms of wire-wrapping and what they mean, so that you may discuss the equipment and tools with your supplier.

First of all, there are two styles of wire-wrapping in use, as far as serially-connected terminals are concerned. One "daisy chain" is shown in Fig. 2(a). "Level-ordered" is shown in Fig. 2(b). Daisy-chain wiring is not recommended, as a moment of study will show that if you wish to change the wiring on two terminal posts (or wire-wrapping terminals) that have been daisy-chained, you may have to remove six wires (the maximum number of wire levels being three), whereas with level-ordered wiring, four would be maximum.

Wires placed on posts by level order are identified as levels 1, 2 and 3, with level 1 being the wire nearest the component board (Fig. 3).

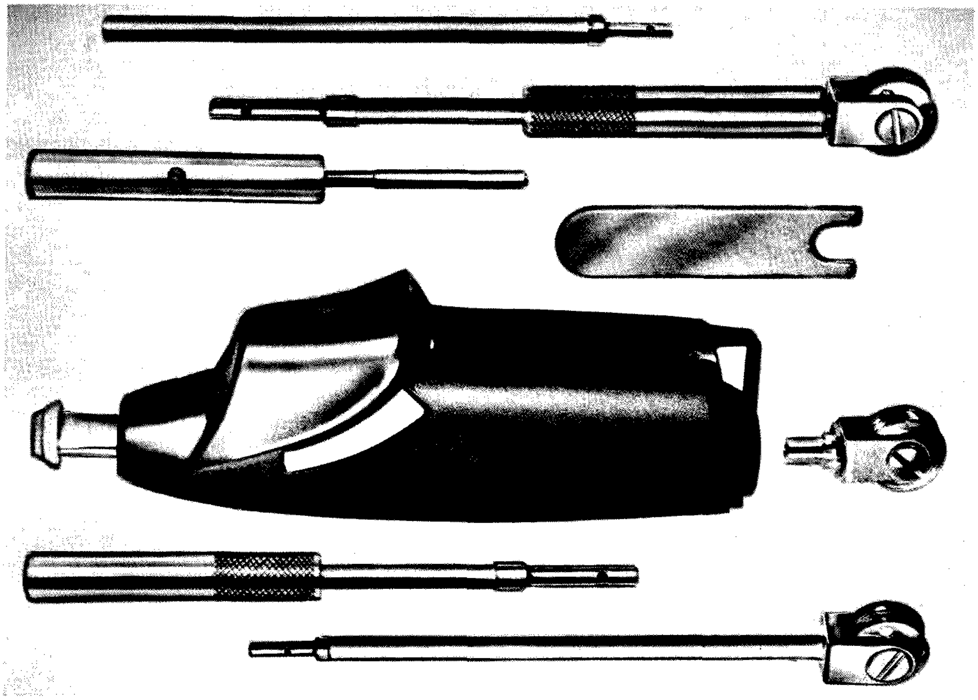

Photo A. Low-cost manual and electric wire-wrapping tools.

Ordering of Wiring

Although not absolutely essential, especially on a smaller project, it may be desirable to *"order"* your wiring prior to commencing the actual job. That is, you must consider that certain wires will go on level 1, certain others on level 2, and so on. The only real reason for this, of course, is for later corrections, modifications, and additions. With all three levels full, and density wiring, it is of immense help to *know* that the wire you wish to remove is on "terminal post 6, IC23, level 2," for instance. This information can be part of your "wire list" prepared directly from the circuit diagram. If you have a good wire list, you can rapidly wire a back panel using wire-wrapping techniques, without reference to the schematic. In fact, electronics laboratories have persons skilled in wire-wrapping, but unskilled in electronics, doing this constantly.

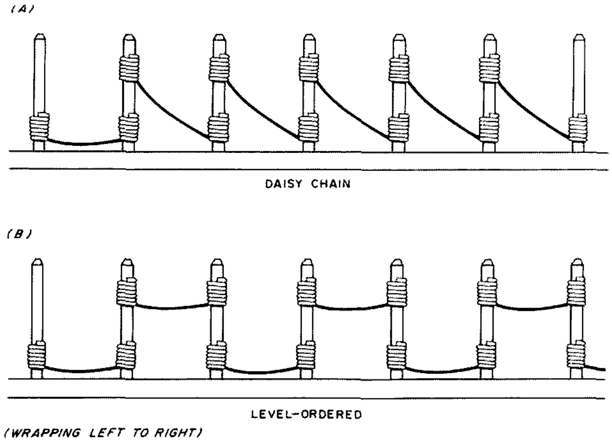

Fig. 2. Daisy-chain and level-ordered wiring.

Wire-listing

Whether or not you level order your wires, do plan on wire-listing your connections as mentioned above when wiring complex circuitry. Make up a wire-list table, as shown in Fig. 4, and, working from the schematic, such as that shown in the figure, draw a line through the schematic as you enter the information on the wire list.

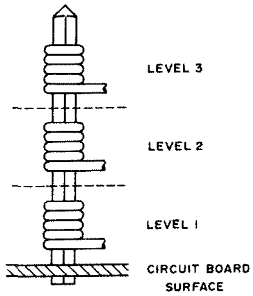

Fig. 3. Level orders of wire-wrapping.

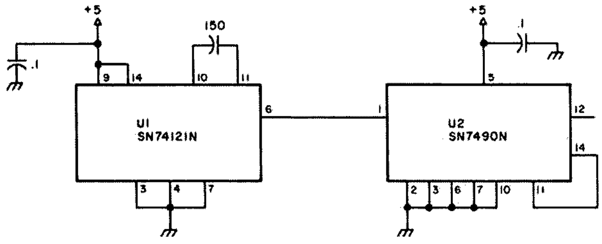
Check this over, and your chances of wiring error are minimal. If you *do* mis-wire, locating your error is done quickly.



Component Reference	From	To	Remarks
U1	U1-9	+5	Vss
	U1-9	U1-14	
	U1-9	.1	.1 uF to gnd
	U1-10	150 pF	150 pF to U1-11

	U1-4	G	Chain
	U1-7	G	Chain
	U1-6	U2-1	
U2	U2-5	+5	
	U2-5	.1	.1 uF to gnd
		etc.	

Fig. 4. Typical wire-list table.

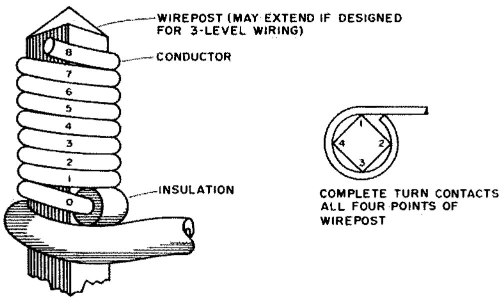

Fig. 5. Turns application to wirepost.

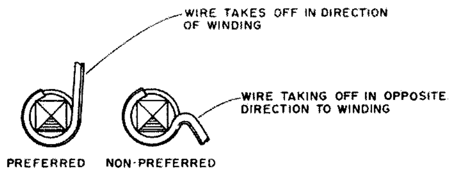

Fig. 6. Preferred way for wire to leave post.

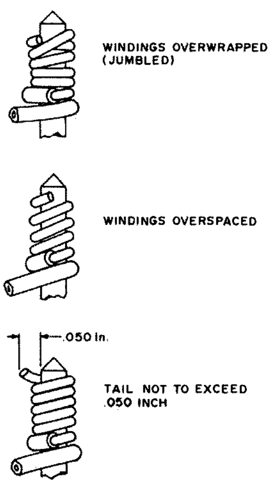

Fig. 7. Three types of unsatisfactory wraps.

Wire Application

Using conventional wire-wrapping tools, whether electric or manual, is the same, as far as the wiring on the post is concerned. We say "conventional," because later on we are going to describe some newer tools that have been produced with you, the at-home constructor, in mind.

Wires wrapped on a post should look like the greatly enlarged sketch in Fig. 5. The number of wire turns should be six of bare wire (plus two turns, minus one turn as a variable), in addition to one-half to three-quarters of a turn of insulated wire. This also is shown in the above figure, and applies to wire sizes of no. 26 AWG (0.0159-in.) or smaller. The purpose in allowing some insulation to wrap around the post is for strength and to avoid short circuits (as could happen if several wires bared of insulation extended from the posts).

A completed turn is considered as having been made when the wire has made contact with all four corners of the terminal post (Fig. 5).

Even though only one wrap is needed on a terminal, always put the first wrap at level 1. If you find it necessary to unwrap a wire from a post, never attempt to reuse it, but remove the other end also, and discard the wire. Once applied and removed, wire is structurally damaged so that it is totally unreliable for reuse. Caution should also be used in attempting to reuse terminal posts too many times. After ten or so wraps and unwraps, inspect the post closely, with a magnifier if possible, for damage such as loss of plating, corrosion, nicks, and structural weakness. This is more important if a powered wrapping tool has been used, as manual use is not so likely to apply as many stresses.

Route your wires rather openly from terminal to terminal. It is not unusual to loop the wires in an upward direction and dress them carefully later. Do not draw them tightly around other posts or parts, and never kink or sharply bend the wires. As long as electrical factors such as rf, hum, choke effect, etc., are not a consideration, multiple loops are acceptable in order to take up slack if the lead is too long. Always inspect the wires as the work progresses for any bare spots that may have been made in the insulation of the wire between wiring points. Never repair; always replace, if any are found.

Whenever possible, have the wire wrapped on the post in an orientation that allows the wire to leave the post without any tendency to unwind, as in Fig. 6. This means that you should always look ahead to see where the next post is that is to be connected.

With most tools, you cannot make other than perfect wraps. However, a non-perfect wrap, should it occur, is one that has the wires "jumble-wound" (a wire on top of itself in a spiral) or a wire that has too much space between each turn (should not be more than one-half the wire diameter). Last—but certainly very important because of short-circuit potential—do not permit the end of the wire resulting from the last turn to project out from the post more than .05 inch (1.3 mm). Spacing between two of these wire ends should be a minimum of 1/32 inch (.08 cm). See Fig. 7.

All of the preceding makes wire-wrapping sound difficult and complex—which is far from being true—but these hints are merely ways to do the job well. Now let us consider some of the tools that make the job easy.

A wire-wrapping tool used in a power-operated device is known as a bit, just as for a drill. Bits are provided to accommodate various sizes of bare

wire, e.g., no. 22-24, 24-26. A sleeve, customarily used, is insulated and protects adjacent terminals. The bit rotates within the sleeve. Photo A shows several wire-wrapping tools.

A tool for manual operation is known generically as a wire-wrapping tool—sometimes as a hand-wrapping tool. A number of trade names are in use. We also have "unwrapping" tools, discussed later.

The basic tool is composed of a handle, as a screwdriver has, and a narrow cylinder about two inches long. The operating end is approximately .070 inch (1.8 mm) in diameter to permit easy working between terminal posts. These tools are usually made of metal, although one manufacturer produces a low-cost tool made with fiberglass filled nylon. A tool manufactured by Vector Electronic Company, Sylmar, California, uses a hardened beryllium copper bit, and can easily wrap multilevels. This particular tool will accept no. 26 through 30 gauge wire, and has the unique capability of accepting bare wire through the top end for continuous wiring.

The bit end of the tool accepts the bared end of insulated wire or the end of uninsulated wire. The principle of inserting the wire and wrapping is similar. The enlarged view of the bit end shown in Fig. 8, through the courtesy of Vector Electronic Company, Inc., is used here for illustration.

The wire to be inserted should be held in one hand with your thumbnail 1.3 inches (3.3 cm) from the end of the wire. The side of the bit that has the wire tunnel may be identified by the probe hole on the side of the tool tip.

Holding the tool horizontally, or with the tip elevated slightly, insert the wire end into the tunnel. If the position of the wire probe hole has been noted, there should be no problem. But if you have inadvertently inserted the wire into the wirepost hole, the wire will not enter as far as your thumbnail holding the wire. Therefore, remove the wire and try again. Once it is inserted correctly, remove the wire about half of its length, bend it slightly and reinsert it. This will hold it securely. Now, releasing the wire, bend it at 90° at the tip.

Place the tool down over the wire-wrap post, and route the other end of the wire toward the next terminal post to be wrapped. Hold the loose end of the wire to the board with a firm but soft tool (an alignment tool is good for this, or a small screwdriver with a piece of heatshrink tubing on the end), make one clockwise turn using no downward pressure. Continue, using slight downward pressure, for the full number of turns. If the amount of insulation removed is correct for the number of turns, the tool should release itself. But if you continue to turn and exert downward pressure, jumblewrap (or overwrap) will result.

Wires may be stripped as you wire, using standard wire-stripping tools (they must be for the small wire sizes used, of course), or you may strip ahead of time. Considering the relatively minor cost involved, this rather irksome task may be avoided by purchasing your wire pre-cut and pre-stripped. The Cambridge Thermionic Corporation (Cambion®), for instance, supplies kits of 25 pieces each of 1.5-, 2.5-, 5.0-, and 7.0-inch (3.81-, 6.35-, 12.7-, and 17.78-cm) no. 30 AWG kynar-insulated wire. Each length is stripped one inch (2.54 cm) on each end.

Unwrapping may be done by carefully gripping the wire with needlenose pliers and unwinding the spiral. But this is tedious and time-consuming if many unwindings are to be made. An unwrapping tool, manually operated, is very low in cost and should be on hand.

In order to unwind a wrap, all that is necessary is to place the tool over the post, press it down slightly, and turn it counterclockwise. As previously mentioned and again emphasized—discard the wire.

One rather innovative approach to prototype wire-wrapping has been made by Vector. The tool used for this purpose is the Model P180, and has been designated "Slit-n-Wrap." A Motor-driven model, the P160-4T, is also available, but utilizes the hand tool as a driving bit, thus permitting you to upgrade your initial purchase if you desire.

The wire normally used for this tool is no. 28 AWG, nylon-polyurethane insulated, but it is also possible to wrap using standard no. 28 or no. 30 gauge pre-stripped and pre-cut wire. The wire may be obtained in clear, red, green, or blue, and is run from a spool attached to the top of the tool.

The system has been designed so that six turns provide extremely low resistance connections, each contact being approximately 0.003 Ohms. The secret to the success of this tool is in the removal of insulation from the wire as it passes over a narrow sharp edge in the bit. As the tool is rotated, the wire rolls along a path from this sharp edge to the wire post, which further opens the slit in the

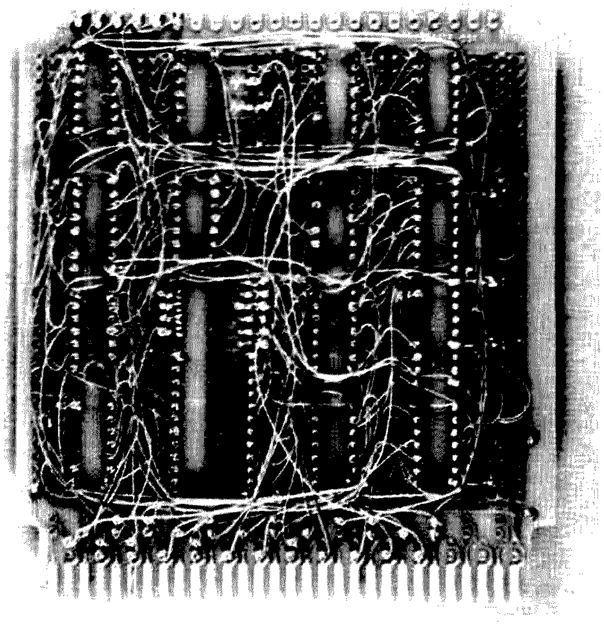

Photo B. Typical wire-wrapped circuit board. This board is of "universal type" with printed circuitry on opposite side.

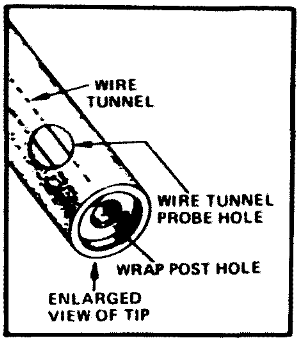

Fig. 8. Wire-wrap (Vector).

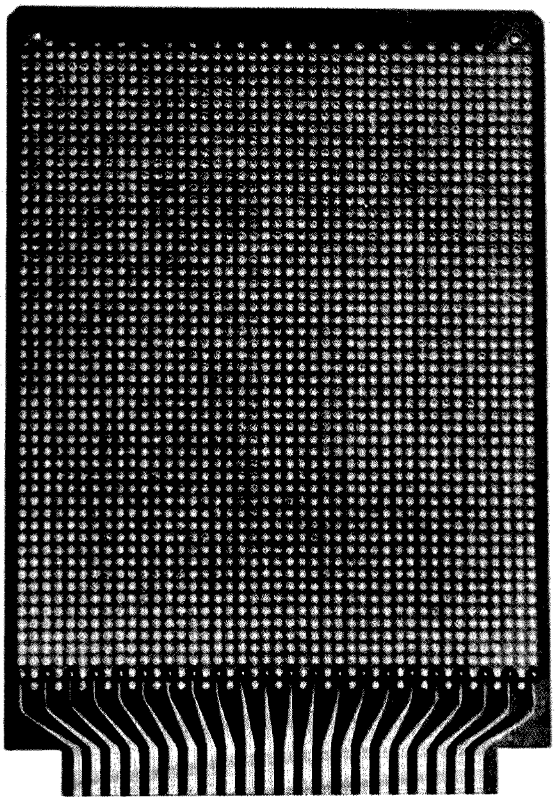

Photo C. Universal perforated board with end connectors (PLUGBOARD by Vector).

Fault	Probable Cause
Spiral or spread out wraps	Lifting tool during wrapping
Overlapping (jumble) turns	Excessive downward pressure during wrap
End tall too long	Removing tool before sufficient rotations have been made
Insufficient turns	Insulation not stripped back far enough. Wire not inserted fully into bit
Excessive turns	Too much insulation stripped

Table 1. Wire-wrapping problem guide.

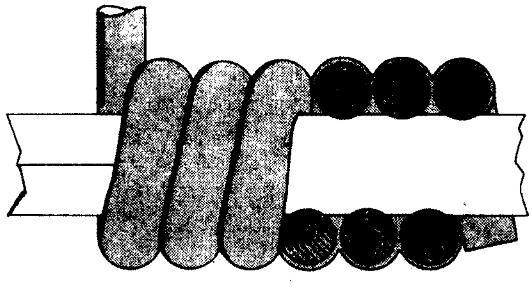

Fig. 9. Cross-section of "Slit-n-Wrap" connection (Vector).

insulation at the point where the bare copper contacts the post. The wrapping action indents the wire and the post, to produce gastight joints (seven turns will produce 28 contacts). Insulation removal only occurs when wrapping takes place, not when wire is removed from the tool.

Fig. 9 shows a cross-section of how the wire wraps on the post. Any insulation that is displaced reforms in the space between the wire turns. Wire is held close to the board (when starting or moving to the next terminal) using a dull wire-holder. No looping is necessary, and this type of wiring is amenable to daisy chaining. Wire is not cut until the end of a run or until a circuit path is reached.

Circuit Boards for Wire-wrapping

You may design and make your own PCB that will permit you to use wire-wrapping techniques. You may purchase "universal" PCBs (Photo B) that allow complete flexibility of design using wire-wrapping. And you may purchase component boards containing prepunched holes for mounting parts to be connected by wire-wrapping.

The technique of wire-wrapping is the same in each case. However, with a board etched for a specific project there is little or no flexibility, which is intended.

Universal-type wrappable boards have an overall grid of 0.042-inch-diameter (1.1-mm) holes on 0.1-inch (2.5-mm) centers, and use tinned interleaved buses. Any one or more Dual In-line Package (DIP) sockets may be installed anywhere on the boards. If parts such as resistors and capacitors are placed on the board, they should be installed using component carriers in order to take full advantage of wire-wrapping shortcuts (or, the circuit paths may suffice). A component carrier looks like an IC with the "lid" off, has wire-wrap terminals in this case, and on the open top surface has solder terminals to accept resistors, etc.

Sockets are also available for SCRs, transistors (all cases), and other components.

At least one manufacturer produces these boards with card connector terminations on one edge. This makes each board a separate entity within a system, with only the edge connector receptacle wiring between boards needed to complete the system.

End connector boards, by the way, frequently develop open circuits between the card and the connector. This can usually be corrected by removing the card and then reinserting it. If this doesn't work, the edge connections should be cleaned with alcohol, or even with a soft pencil eraser.

Component boards, made up of either epoxy paper or epoxy glass, use no copper etching paths except possibly as an edge connection. Typical of these boards is the one shown in Photo C, again manufactured by Vector under the name "PLUGBOARD." As in the case of etched boards, this carrier has 0.042-inch holes on 0.1-inch centers. A great deal of flexibility can be used in making prototypes with these boards, as parts of any reasonable physical size may be placed on them. They also have the advantage of being less costly than etched boards.

Wrapped-wire-type square pins are obtainable to insert into the holes on component boards or to use as parts holders or connecting points.

Wire-wrapping Problem Guide

Causes and cures for wire-wrapping problems have been mentioned throughout the preceding paragraphs. These have been summarized in Table 1. If you encounter difficulties in your initial wire-wrapping endeavors, check the table to analyze your problem. ■

Working with Transistors

—useful knowledge begins where gobbledygook ends

Author's Note: This article was about to be sent in to *73* when an excellent article, "*73* Reveals Bias," by Carl C. Drumeller W5JJ, appeared in the September, 1978, issue of *73*, p. 136.

He used a method very similar to mine to determine transistor component values. There are differences in our approaches, though, and this article also covers material which he did not present. So, after talking with *73*, it was decided to go ahead with this one, too.

I recommend that you compare the two approaches to the problem and particularly note the different choices we each made in circuitry as well as the similar pragmatic answers.

Some years ago, I was able to take the Navy's "two-pound" course in basic electronics. It starts with "this is an electron," and ends up with "this is a computer."

There was a full section on transistor theory and application. This was good, as I didn't know anything about transistors.

By some fluke, I completed that part of the course with a high score. I also came away with one other important piece of information: I still didn't know anything about transistors.

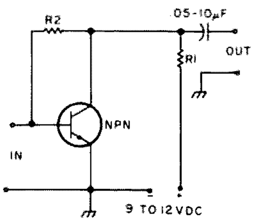

Fig. 1. Basic transistor voltage amplifier.

This was not the fault of the course or my lack of application. The information was centered on having total control of specifications and technical information on the devices being used.

Out in the real world, the slide-rule approach simply would not work at all. I never could get all the info needed to work the formulas, and I still did not have a firm grasp of what I was trying to do.

Contrast the almost religious devotion to the slide-rule approach to transistors with the usual way one learned about tubes, as I was introduced: Here is a tube (a type 30). It has a filament, a grid, and a plate. You connect three volts and a rheostat to the filament, like this, and the B battery to the plate circuit and one side of the filament, like this. Now, here's how you hook it up to make a radio (a one-tube regenerative set). Don't hook up the B battery backwards and don't connect the B battery to both sides of the filament or you'll burn it out.

That and a book of old tube circuits was about it as far as the theory was concerned. Then I was in business. The time required from start to finished product was the better part of an afternoon. If there was such a thing as the electron theory, parameters, and other assorted drivel, it was not mentioned and was not missed for some years.

A slight amount of reflection should yield the following: The 30 took two voltages. A transistor only takes one. Therefore, a transistor should be easier to work with than a tube. Why isn't it?

Basically the problem is gobbledygook—too many words got in the way. The transistor had to be sold as something new and different and an entire mythology was created to obscure everything about the transistor. You can hardly make head or tail of the little beasties. The nice thing to remember about transistor mythology is that most of it is bunk. What's needed is some how-do-you-use-it information and this is much easier to get than is commonly thought.

First of all, we need some parameters. What's a parameter? That's a catch-all phrase to cover all of the operating conditions of your pampered little transistor.

Tubes have parameters, too, only they don't know it. They have a maximum voltage for the filament, one for the plate, voltage limits between other elements, a maximum current, maximum signal input, etc. With tubes, it's no big deal, but with a transistor, everything gets a fancy title. Let's try and isolate what we need from the rest.

Transistors can work with one voltage. This is the supply voltage. It has a maximum value which the device can take. As with any device, but particularly with a transistor, you don't even want to come close to this. Figure a design maximum of 12 to 18 volts for most uses. The maximum rating is usually more. They also have a maximum current rating just like a tube does, but instead of the plate glowing cherry red and giving you a chance to shut it off, transistors go pffft the first time. Dead transistors are nature's way of telling you not to do that again.

While there are a myriad of transistor parameters available, the only other one that you need to know right now is the maximum voltage which can be applied between various elements. The next biggest cause of a terminal pffft, after too much collector current, is too high of a signal being applied to the base or emitter junctions. Too much signal will blow them. In time, you may want more parameters to play with, but those are enough for the cut-and-try experimenter.

There are reams of equations for determining all the resistance values in a simple transistor amplifier circuit. Since you probably won't have the information you need for them, there has to be another way. At least this is what I thought after sitting and staring at my collection of unknown transistors. I had come through the course in fine shape but I sat there without the faintest idea of what to do. A few basics came to me. I had little information, my transistors were unknown, and what was the worst thing that could happen? I could blow out a nickel transistor. That's not too bad for some experience. But, as I worked on just how to do it, some of the course material trickled through to the top.

It is these cut-and-try basics which I will try to present as an organized approach to starting to experiment with transistors.

Transistors are of two main types, PNP and NPN. This refers to the polarity of the internal material. This is theory, but there are theoretical and pragmatic considerations which are important about this.

In many of the older types you might work with, the NPN version of an identical PNP type might have a higher frequency range than the PNP transistor. This might be important in some circuits. Also, the polarity of the device determines how the polarity of the supply hooks up. The NPN is the one which hooks up with the same polarity that you are used to with tubes.

The B+ goes to the collector (plate) and the minus goes to the emitter (cathode). This makes it easy to get it right. Also, a pragmatic effect which I noticed was that, in many cases, the identical circuit was far more stable using an NPN rather than a PNP. There is one mechanical disadvantage to working with NPN power transistors; this is heat sinking. Here the voltage polarity works against you. It's nice to be able to work with the same voltage polarity as with tubes, but you pay for it when compared to the PNP.

With a PNP, the collector gets the minus voltage. With most power types, the collector is also connected directly to the case. With a PNP transistor, you can then mount the transistor directly on the chassis and also make the chassis be ground for your supply. A heat sink may or may not be needed, too, but it also can be grounded to the chassis directly.

With an NPN, you can't just do this. The usual method is either to use a transistor mounting kit with a mica washer and insulated hardware so that the transistor can still be mounted to the chassis, or to insulate the heat sink from the chassis.

I never was too happy with the washer method, and prefer the separate heat sink, but there is still a disadvantage to this: There then becomes a voltage difference between the chassis and the heat sink or transistor which might be a safety hazard. The best bet here is to shield the heat sink so that direct contact with it is avoided. You can connect the transistor directly to the chassis if you make your plus voltage the one which is grounded and leave the minus floating. If there is an internal supply for the unit, this is not hard to do. However, it is confusing, to say the least, and if there is other equipment connected to the unit, you may have conflict between various ground connections and power supplies.

For most breadboard use, I just used the transistor mounted on a big heat sink by itself. Connections were made by sloppy clip lead, anyway, so the problem of mounting the transistor in equipment never came up. It worked for test purposes. If I wanted to produce a finished circuit, I would go for the insulated heat sink and shield it mechanically so that there would be no shock hazard.

There may be times when a special purpose needs a PNP transistor, but for starting out and most uses, divide your transistors first by NPN and PNP. Then put the PNP transistors away where you will not be tempted to use them. The remaining NPN types can be roughly divided into three important main categories. These categories reflect both a basic application and a rough measurement of their power-handling abilities. The three categories are: small signal—up to 10 mA of current, general purpose—10 to 100 mA, and power types—100 mA and up.

This disregards the distinction between audio, rf, switching, or other special-purpose types. It does, though, give a rough guide for immediate application and to introduce a way of thinking. Your two basic immediate needs are to see that the device does not have its ratings exceeded, and to see that it is not overdriven.

To start with a mostly-unknown transistor, assume that it is a small-signal type. By the way, many large-signal or higher-power devices can also be used for small-signal use, and do a very good job. The basic transistor amplifier circuit is usually

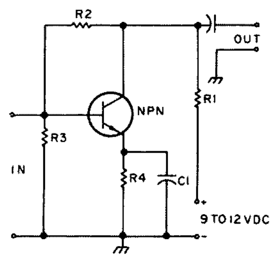

Fig. 2. Complete textbook circuit.

a small-signal application, both in audio and rf. It makes an ideal place to start.

Some equipment will be needed for experimentation. Besides the usual transistor hardware and parts, you will want an oscilloscope, a VOM, a resistance substitution box or handful of potentiometers or resistors, and a signal source.

Start with a microphone. It's safe. An FM tuner or audio signal generator would also be nice for further testing. An adjustable amplitude is highly desirable. The simple one-stage small-signal transistor voltage amplifier is a fiend to design by formula but it is quite easy to do pragmatically. This is where some of what the course taught me really helped. The basic circuit is shown in Fig. 1. R1 and R2 are the two key resistance values in the circuit. They will have to be arrived at experimentally but it is quite easy to do once you get the hang of it. The important thing is the safety of the device. Protecting the transistor is what takes up your time at the start and makes it seem a little clumsy to do.

According to theory, a class A transistor amplifier will draw half its allowable current at rest (no signal). The output signal goes above and below the midpoint. This gives us two assumptions. The first is that we are using a small-signal device (even if we are not). This also means that we are limited to 10 mA.

Our first practical calculation is a resistance value which will limit the current to 10 mA in the worst case, that is, if the transistor were a dead short. This gives you a value of R1. This is not critical, so pick the next highest resistance which you have if you can't get the exact value. Remember, this will not be the actual final value, but a working load resistance to start with which will protect the device.

In most cases, the actual value for best results will probably be much higher —similar to a triode tube voltage amplifier which usually has quite a high load resistance. However, start with the value derived in that manner. Hook up your VOM to measure the actual current at the collector. At this point, with one resistor, there should be no current. Without some form of bias to the base, the transistor should be cut off and no current should flow.

Now, take your resistance substitution box and, starting with the highest value at R2, click your way down until the transistor just starts to draw some current. At this point, there should be some indication that the circuit is functioning. Use your mike and a sensitive range on your scope, and watch the waveform. I also used the output from an FM tuner. Even at these low levels, I got an indication of circuit function and could see obvious distortion or clipping. The circuit should work, but not too well. Here is where the fun starts.

Replace the substitution box with a fixed value at R2. Put the substitution box in place of the fixed value at R1. Starting at the original R1 value, increase it and see what effect it has on the signal. You should get more amplification and less distortion up to a point. If you don't, try going a few clicks in the other direction, but watch the meter. When you get better results, replace the box with the appropriate fixed value and go back to R2 with the substitution box and see what effect changing that will have. A simple circuit like this should have quite a range of practical values over which it will work. It should only take a few back and forth trips to make an optimum choice.

At this point, you have a working amplifier. Usually there are a few more resistors which get put in the circuit for stability or other reasons. These get put in last. They are shown in Fig. 2. R3 is not critical. There is a simple formula for doing it by math: R3 is usually about 1/10 the value of R2. R2 and R3 act as a voltage divider and also help to tame the base-emitter circuit by providing a load to help limit current flow in the circuit.

When you have the basic circuit going, just hook up the substitution box and see what effect different values of R3 have to the actual signal. Start high, and as you click down, the signal will begin to be attenuated by the resistance. At that point, or a little lower, is the point at which you want to stop.

R4 is another matter. It is something like a cathode resistor but it doesn't work the same way. It also has a stabilizing effect on the transistor circuit, and helps limit the current of the stage. It also may have the effect of permitting a wider range of input signal without distortion. That doesn't mean you can exceed the element-to-element rating, but, as with tubes, the added bias can place the signal on a more-favorable part of the current curve.

Use your scope and a variable input. The values are quite similar to the tube values, several hundred Ohms, with 1000 and 2200 Ohms used quite commonly. Watch the scope and see at what point your signal starts to distort or clip. Put in the resistor and see what effect the values have on the signal. If there is an improvement, increase the signal to get the distortion again. Try different values and see what that does. You may want to go back and try some new values for R1 and R2 at this point, too. However, R4 will probably be a minor factor in the overall amplifier circuit.

As with vacuum-tube cathode resistors, the emitter resistor is usually bypassed. This is a husky electrolytic often in the same range as those used with a tube. 20 uF on up to a few hundred uF are common values. When the resistor is not bypassed, it also has some degenerative effect. The output will be less, but you will also get the stabilizing effect of an emitter which is not bypassed. You can see the difference on the scope as you try different resistance values or bypassing. Just play around with a few electrolytic values and watch what happens.

The main killer of transistor circuits is heat. They have the habit of drawing more current as they warm, which makes them warmer and they draw even more current, and pffft. If you work well within the ratings, you should have little trouble. Most devices are run too close to what they can handle.

The only other thing is to keep it from becoming externally heated. Don't put the transistors right over the power transformer. Allow room for ventilation. If you avoid extremes of both heat and cold, you should get reliable results with this circuit. The only way to assure operation at temperature extremes is to test

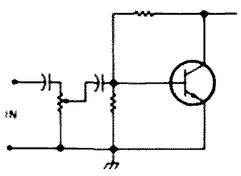

Fig. 3. Transistor volume control.

your circuit at the temperature extremes which you will normally encounter. Use husky transistors and parts and derate them for extremes. With care, this should not be any great problem.

Input and output circuits provide little problem with this stage. Capacitor coupling is easy and common with such a circuit. The value is not critical. 10 uF, or so, is a common value.

The real stinker is the volume control. You can't just hook up an audio-taper pot in place of R3. When you turned it down, it would become a dead short across the emitter-base junction. A circuit such as that shown in Fig. 3 will do the job. A few extra parts are quite cheap at transistor power levels.

You can use one or two stages which are similar for an audio amplifier, depending on how much amplification is needed. The output will be high impedance and will drive a high-impedance pair of headphones with sufficient volume. More stages can lead to troubles such as feedback or motorboating. There are two things at work here. The higher gain of cascade stages is a troublemaker and the additional wiring picks up anything.

Driving a speaker is not hard to do either, if you are not overly squeamish. Much attention is given to proper impedance matching with transistors. If you can just ignore that urge, you should be okay.

Start with the circuit of Fig. 4. The transformer should be a medium-to-low-impedance transformer. It probably should be critical, but I have used anything from a 48-Ohm c-t transistor output type to a replacement tube type. Use the 8-Ohm output and whatever primary you have to start with. Here you just do the same thing that you did with the load resistance procedure. Adjust R1 with one eye on the VOM, and listen to the output.

It would be assumed that you would start with an audio power type, not a small-signal type. Then start drawing some current and listen for what you get. This circuit will not be the most efficient, but you will be surprised just how loud even a small amount of audio can sound.

I found that an amplifier in the range of 200 mW to a Watt, or so, was quite practical with this sort of set up. In fact, I even hooked the speaker coil in alone in place of the transformer. I don't recommend the practice, though. It's too easy for the steady dc current to exceed the rating of the speaker winding, and burn out an expensive speaker. It does improve the frequency response, though. With care, even with a junk-box transformer, there will not be any serious loss for communications use, and even music may be acceptable.

It is always stressed that the transistor is a current-operated device; you always get current ratings but little is said about voltage. Your total output power is the signal voltage times the current through the impedance which you are using. The value can be found by Ohm's Law.

For example, the measured output voltage across the speaker winding divided by the impedance gives you the current (ac). The voltage is again used to calculate your power output. Or, even easier, use $P = E^2/R$.

It usually is thought that you get more output if you can get the transistor to deliver more current to the speaker coil. It's a nice theory, but just drawing more transistor current doesn't automatically deliver more output. As effective output goes up, so does the output current and the output voltage. At no point can the effective output voltage exceed the actual supply voltage to the transistor. It usually will be somewhat less. While your formula sounds great that 12 volts at 2 Amps would give you 24 Watts, at twelve volts, the transistor may not deliver that two Amps.

Enjoy the extra safety margin. You can get enough from just a simple power stage to hurt your ears at close range. Here, too, watch the scope for distortion. Measuring your output voltage values will give you the full story. When you drive the transistor to its supply voltage, you get clipping and distortion.

A common thing with transistor amplifiers is direct coupling between transistors. This is one of the all-time headaches to design and debug. Or repair, if it comes to that. Without going into convulsions on how to do it, there is one basic circuit configuration which is easy to play with, shown in Fig. 5.

Q1 and Q2 can be small-signal types. Q3 is shown as a 2N3055, which is quite common. I have used three 2N3055s and a number of oddball combinations. Try for some sort of method to your choice.

There is one important consideration you should keep in mind when working with power transistors. They are very rugged current-wise when compared with the smaller ones, but many of them can only accept a small input voltage without damage. Many which I worked with would only take about four volts between emitter and base. Many small-signal types would take 35 volts between emitter and base. That's a very strong case for using small-signal types to drive the power stage for you. Also, in many cases, the small-signal type will be more sensitive to weaker input signals.

An FM tuner is a high output signal source. So may be the output from a detector in a receiver. However, in a simple set, the audio stages may have to supply some of the small-signal gain needed for the set. Try some combinations when you work with these circuits so that you get a feel for different operating conditions.

I have worked with many sets which had impressive bench test specs, but on-the-air tests with weak signals showed the importance of real sensitivity to weak signals and the effect small amounts of change in distortion, clarity, and other conditions have. You just do not notice these effects without real on-the-air testing.

R1 is chosen the same way as in the first amplifier: first for the current, and then for the sound. This amplifier is about the simplest "complex" amplifier that you can build. The first two stages are working as voltage amplifiers and the last is the power output stage. This circuit will also work well with just two transistors if less preamplification is needed.

I did not build these circuits into any equipment. I just used these circuits to learn on. However, I found even the simple circuit like Fig. 5 to be quite stable. I had it running on the bench for hours at a time as an amplifier for an FM tuner, and most of the other successful circuits worked

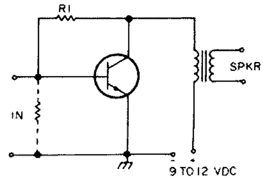

Fig. 4. Basic transistor power amplifier.

well with no problems. Even without all the resistors which a classic circuit is supposed to need for stability, they just sat there and worked for hours on the bench.

I think the key is to pick husky transistors and run them very conservatively. The power amp only draws a few hundred milliamps resting, if that, and the first stages use a tiny amount of current. However, as stated earlier, many of these stages were tried with the PNP transistors which were exact equivalents, and there was trouble. It appeared to be thermal runaway. The stage would start drifting into a higher-current condition and then I would get distortion and other problems.

There did not appear to be an easy fix for this condition. Even though the circuit could be stabilized so that it would not draw dangerous current, it was not tame, which means it's not reliable. And yet the same circuit with NPNs was a joy to work with. Stay away from PNPs. They will lead you into trouble.

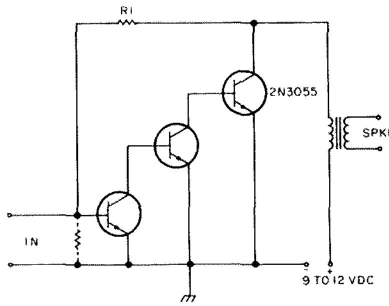

Fig. 5. Simple multi-stage power amp circuit.

There are a number of other simple configurations which can be done with just a few transistors. Any good transistor manual should have a number of basic circuits which can be tried.

There are also combination circuits using both NPN and PNP transistors tied back to back. Stay away from the more complex direct-coupled circuits with lots of components, dual power supplies, and the like. You get into servicing and reliability problems which you really don't need.

I found that none of the other simple combinations which I tried really gave me anything which these simple circuits didn't. There were differences in operation, but they were not significant for any normal use which I wanted to make of the circuit.

By the time you have played for a few weeks or a month with these simple circuits, you should have gotten over the fear of transistors. Then you will have built-in safety procedures to use when you are breadboarding, and it should not be hard to progress to more specialized simple circuits such as i-f amplifiers or rf circuits.

If you play by the important transistor rules and ignore many of the rest at first, you can learn a lot about the exact function of the circuits, how to get them going without formulas, how to deal with parts substitutions, and how to get wide operating tolerances.

You will learn to see what is actually happening inside the circuit as you make changes. The faults you find will also help you to debug other circuits which you may work with. ■

A Digital Clock with Analog Readout

— this is progress?

G. Windolph W9IEA
PO Box 3305
1901 N. 18th St.
Quincy, IL 62301

The clock described here brings you the best of two worlds—the digital and the analog. It combines the reliability of the no-moving-parts, all-electronic clock with the instant readability of a clock with hands.

I built this clock for two main reasons. In the first place, I wanted an all-electronic clock that I could read from a distance of three or four feet in the dark without my glasses. If you happen to be as myopic as I am, you know that the ordinary digital clock might as well be just a night light after you have retired and have put your glasses on the shelf. This clock face can be as large as you wish.

In the second place, I wanted a clock that gives the instant readout of the old-fashioned clock with hands. One swift glance at an old-style clock and you know immediately how close you are to that 1:00 deadline. With the ordinary digital clock reading 12:53, it takes a bit more than a quick look to tell you that you've got seven minutes left. There's something about a clock with hands that makes 8:20 look like "twenty *after* eight" and 8:40 look like "twenty *to* nine." This visual shift doesn't occur with a digital readout. I suspect that this is one reason why Texas Instruments has come out with an analog readout on a digital watch. I predict that the clock-makers will follow suit. Even if you're not a nearsighted clock-watcher, you may find this project to your liking.

General Description

Two concentric circles of discrete light-emitting diodes form the "hands" of this clock. The outer circle is for the minute hand; the inner circle, with a diameter about three-fourths that of the outer one, is for the hour hand. One LED in each circle is on at any given time. Another, LED5, is on continuously at the center of the circles to act as a visual point of reference so that the eye somewhat automatically constructs each hand of the clock out of the central LED and the peripheral minute or hour LED. As additional reference points, particularly for nighttime viewing, there are blinking LEDs (1-4) of a different color located at 12:00, 3:00, 6:00, and 9:00. They show that the clock is running. They also are used in setting the clock, as is explained later.

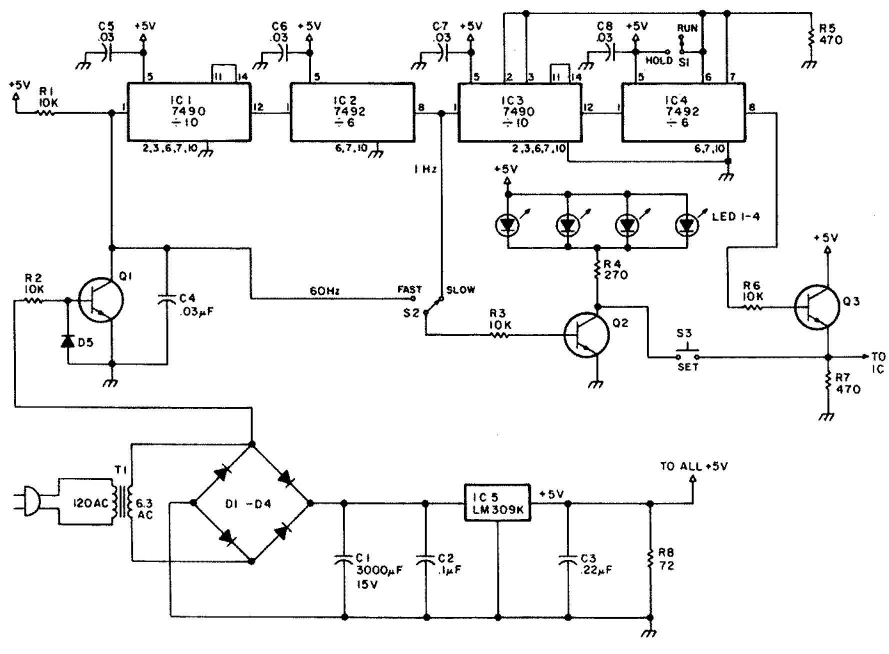

Fig. 1. Power supply and timing circuit.

A one-pulse-per-minute signal operates the clock. A one-pulse-per-second signal shows that the clock is running and, along with a 60-Hz signal, is used to set the clock. The 60-Hz signal is obtained from the collector of Q1, which squares up the sine wave to operate the TTL integrated circuits. This frequency is divided by 10 in IC1 and by 6 in IC2 to give a 1-Hz signal. This is again divided by 10 and 6 in IC14 and IC15 to produce the one-pulse-per-minute signal that operates the clock.

The 74154 integrated circuit is a 4-line-to-16-line decoder. For any binary number from zero to fifteen on input pins 20 to 23, one of the sixteen outputs goes low and turns on one LED. Since there are 60 LEDs for the minute hand, we need four of these ICs. Only one of them is enabled at a time, by a low on pins 18 and 19. the other three are turned off by a high on pin 18 or 19. The 7493 counter, IC6, puts out the binary numbers from 0 to 15 in sequence when pin 14 is pulsed once per minute by IC4. Q3 isolates IC4 from the setting signal. The binary numbers are fed to all four decoder ICs. The one which will give a readout is determined by the 7476, IC7. This is a dual J-K flip-flop which is made to flip every time a negative-going pulse comes from pin 11 of the 7493. This pin contains the most-significant bit of the binary output, and it drops to zero when the output goes from 15 (1111) to 0 (0000). The 7476 puts out a low on the following pairs of pins in sequence: 11 and 15, 11 and 14, 10 and 15, and 10 and 14. These pairs then enable IC10 to IC13 in sequence, and one LED lights up as determined by the binary number on pins 20 to 23. The other 74154s are inactivated since they have a high on pin 18 or 19.

With 64 outputs but only 60 minutes per hour, the last four outputs are unused, and the minute hand would disappear for four minutes if IC13 were enabled for its full count. To prevent this, IC6 must be reset to zero after the 59th minute. The low appearing at the 60th minute on pin 14 of IC13 is inverted by one section of a 7400 and fed to pins 2 and 3 of IC6. This resets IC6 so that its output goes from 1100 back to 0000. The negative-going pulse on pin 11 clears IC7 so that pins 11 and 15 are both low again and IC10 is enabled to begin the first minute of the next hour.

The hour hand functions similarly but we don't need as many LEDs. Twelve would not suffice since there would be a period of ambiguity depending upon when the hour hand jumped to the next hour. One could, of course, use 60 LEDs. I settled for 24, which is sufficient to prevent any ambiguity. When the clock is set on any hour, the hour hand stays on the hour until the beginning of the 16th minute after the

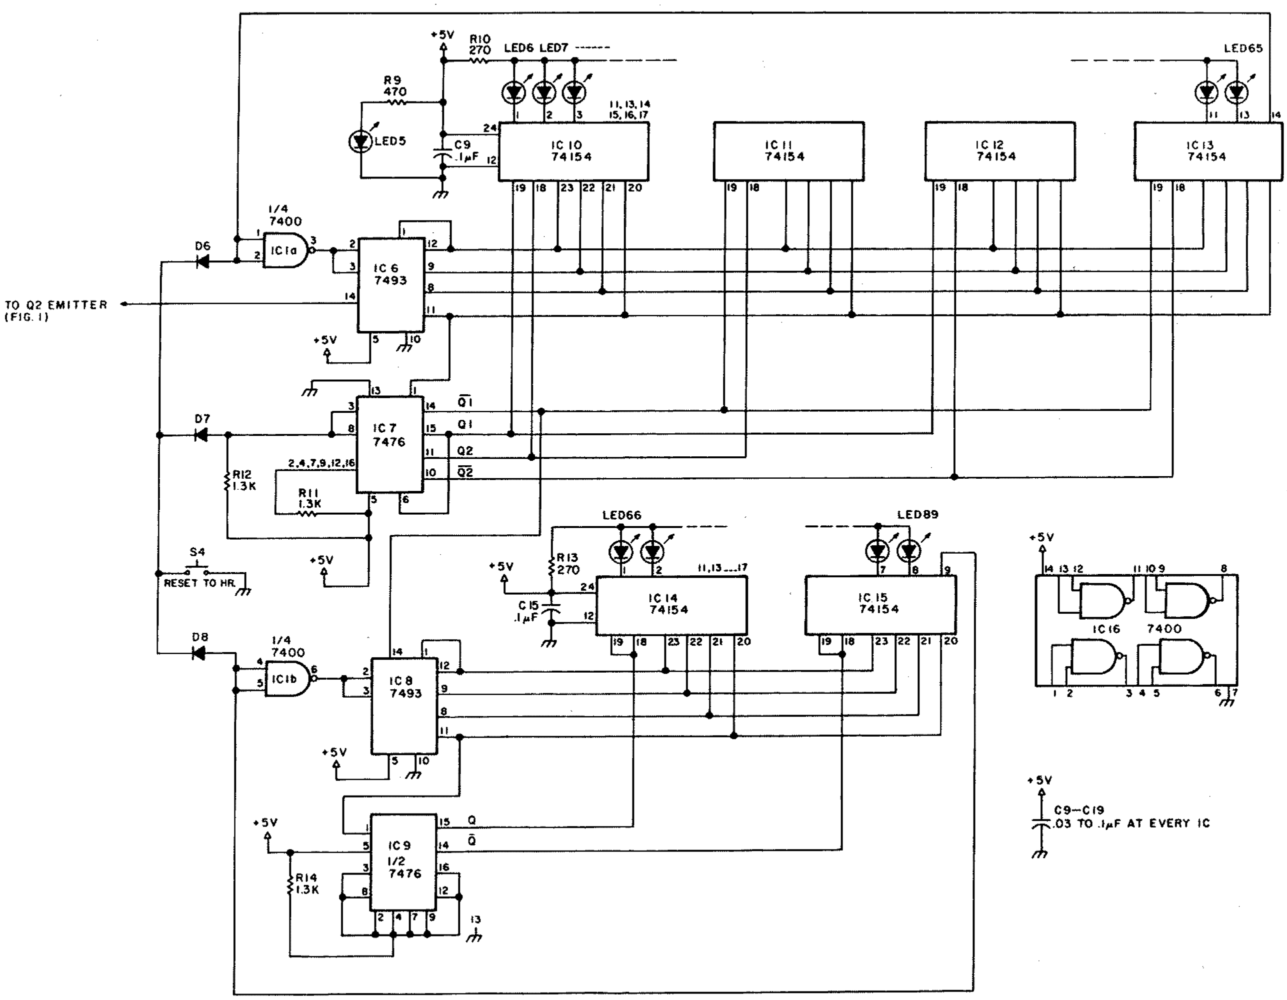

Fig. 2. Readout circuit.

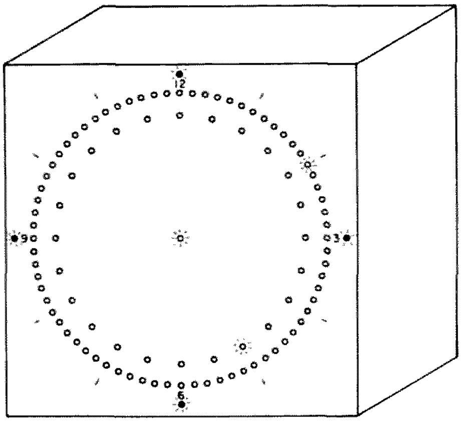

Fig. 3. Face layout.

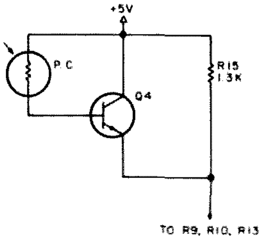

Fig. 4. Dimmer circuit.

hour. It then jumps to the next half-hour point. It remains in this position until the beginning of the 48th minute after the hour. Then it jumps to the next hour position. These points were chosen because signals are available at these times from pin 14 of IC7. The signal from this pin operates the hour hand just as the one-pulse-per-minute operates the minute hand. We need only two 74154s for the 24 LEDs. The hour hand is reset to the zero hour at what would be the 25th half-hour by the output from pin 9 of IC15, just as the minute hand is reset by IC13.

The signal from IC2 turns Q2 on and off, making the LEDs blink once per second and providing a slow-setting signal. For fast setting, the base of Q2 is connected to the 60-Hz square wave at the collector of Q1. In order to start any particular minute exactly on time, IC3 and IC4 are set to zero by S1 which puts a high on reset pins 2 and 3 and 6 and 7, respectively. This keeps the output of IC4 low so that the setting signal from Q2 can pull pin 14 of IC6 low.

The hour hand should be on the hour from 12 minutes before the hour through 15 minutes after the hour. When the clock is first turned on, this may not be the case. By resetting IC6 and IC8 and clearing IC7, S4 sets the clock to 12:00 or 8:00, depending on the state of IC9. This ensures the proper relationship between the two hands. D6, D7, and D8 isolate the ICs from each other.

Checking It Out

After double-checking all the wiring, put S2 in the SLOW postion, then apply power to the clock. The four indicating LEDs should blink. One or both of the hands may fail to light up since there are positions on the 74154s that are not connected to any LEDs, and these positions may be activated with random settings of the guiding ICs (IC6 to IC9). Pushing S4 should remedy this situation, and the clock should read either 12:00 or 8:00. Now put S1 in the HOLD position and S2 in the FAST position. The blinking LEDs should appear to light up continuously since they are now blinking at 60 Hz. Pressing the set button, S3, should make the minute hand revolve once per second and the hour hand jump twice per second. The latter should jump as the minute hand passes from 15 to 16 minutes after and from 13 to 12 minutes before the hour. If either hand doesn't go continuously around but skips whole sections, this would indicate a defect associated with one of the 7476s since they should sequentially enable the 74154s. If either hand disappears temporarily before the 12:00 point, this would indicate that the reset signal is not getting back to the 7493s. Check for a defective IC16, IC6, or IC8. I had a 7493 that counted beautifully but would not reset.

Now put S2 in the SLOW position. Holding S3 depressed should move the minute hand around once per minute while the hour hand jumps twice. Now put S1 in the RUN position, leaving S2 on SLOW. After sixty seconds, which you can count on the blinking LEDs, the minute hand should move to the next minute. If not, check out the divider chain. If the blinking LEDs have been working properly, IC1 and IC2 must be functioning, so check IC3, IC4, and Q3. Also check the wiring of S1.

In general, troubleshooting this clock is not difficult if you understand its operation and analyze the problem accordingly.

Setting The Clock

Put S1 in the HOLD position and S2 in the FAST position. Momentarily push S4. Then set the hour hand with S3, releasing the switch as soon as the hour hand reaches the desired spot to avoid overshooting with the minute hand. Then put S2 in the SLOW position and use S3 to set the minute hand to the next minute. In setting the minute hand, you probably will find that the hand jumps a number of minutes when you first depress S3 or when you release it. This is due to bounce in the switch contacts. It can be prevented by watching the blinking LEDs and depressing and releasing S3 only when the LEDs are *on*. When the LEDs are on, the collector of Q1 is low and, since pin 14 of IC6 is also low when S1 is in the HOLD position, the setting switch cannot send in a series of pulses when it bounces. This method of setting is not difficult, but it takes a bit of practice since you have to watch the blinking LEDs and the moving minute hand at the same time. When your reference clock reaches the next minute and zero seconds, immediately put S1 in the RUN position. The clock should now run correctly with the minute hand changing right on time.

Variations and Options

Since this clock uses a large number of LEDs, I used the cheapest bargain LEDs I could find. Assuming you'll do the same, I haven't specified the type in the parts list. Resistors R9, R10, and R13 will have to be adjusted for the particular LEDs you use.

The blinking LEDs could be replaced by a single one, or by a dozen, if you want one at every hour point. A single LED may not let enough current through to set the clock, in which case a resistor could be added in parallel with it. If you use a dozen LEDs, only some of them may light, or they may differ in brightness. This will require the addition of individual resistors of different sizes to even out the brightnesses.

If you wish to vary the brightness of the hands for daytime and nighttime, add a resistor from +5 V to the common connection of R9,

R10, and R13. It should be large enough to make the clock as dim as you want it for nighttime. Then use an NPN transistor and a photocell as in Fig. 4. As light falls on the photocell, its resistance drops, feeding more current to the transistor, which then partially shorts out the nighttime dropping resistor.

In my first version of this clock, I used a 5316 clock chip for the timing signals, eliminating IC1 to IC4 and Q1. It was a bargain chip because the alarm was defective. If you happen to have one of these chips in your supply and would like to use it, I can furnish the circuit diagram on request. Please send an SASE!

If you find the fast-set signal a bit too fast at 60 Hz, you can connect the fast contact on S2 to the output of IC1, which will give you a 6-Hz setting signal.

Construction

There is nothing critical about the construction, but the TTL ICs can cause erratic operation if they are not properly bypassed. Each IC should have a capacitor connected right at the IC from the +5 V input to ground. The LEDs are wired so that pin 1 of IC10 and pin 1 of IC14 go to the LEDs at the 12:00 location on the clock face; the other pins go to the LEDs that follow, clockwise around the face. I used wire-wrap technique for part of the clock and point-to-point soldering for the rest.

The face of the clock can be made as large as you desire. If it is large enough, the ICs can be mounted on the face itself. A black sheet of cardboard can be used to cover the electronics, or you can cover the whole face with a dark red plastic sheet. I used a dry letter transfer kit to put white numbers on the dark face of the clock. I built a case for the clock out of wood. If you are good at carpentry, you can make this clock into a neat and functional piece of furniture that you won't want to keep hidden in the bedroom. ■

Parts list

R1, R2, R3, R6—10k, ¼ W
R4—220 Ohms, ½ W
R5, R7, R9—470 Ohms, ½ W
R8—720 Ohms, 2 W
R10, R13—270 Ohms, ¼ W
R11, R12, R14, R15—1.3k, ¼ W
C1—3000 uF, 15 V
C2—.1 uF
C3—.22 uF
C4-C19—.03 to .1-uF bypass disc capacitors from +5 V to ground at every IC (not all drawn on diagram)
T1—120 V ac/6.3 V ac, at 2 A
IC1, IC3—7490 counter
IC2, IC4—7492 counter
IC5—LM309K 5-volt regulator
IC6, IC8—4-bit binary counter
IC7, IC9—7476 dual J-K flip-flop
IC10-IC15—74154 4-line-to-16-line decoder
IC16—7400 quadruple NAND gate
S1—SPST toggle or slide switch
S2—SPDT toggle or slide switch
S3, S4—NO push-button switch
Q1-Q4—2N718 or similar small-signal NPN transistor
LED1-LED4—any small yellow or green light-emitting diode
LED5-LED89—any jumbo red LEDs
PC—VT133L or similar photocell

Turn Off Repeater Windbags

—HT mod brings welcome relief

Gary L. Long WD5HYQ
Route 5, Box 267
Muskogee OK 74401

At last a nifty circuit is available that can be used in the Wilson 1402 to make it a monitor (automatically).

Perhaps you are one of those people who really like to monitor the repeater, but find that there are always those few hams around chewing the rag so that continuous monitoring is more trouble than turning off the rig. Well, cheer up, Bunky, I have just what you need—a time-delay circuit that lets the Wilson operate normally for about 10 seconds after the squelch opens and a call is made or a conversation is started. After the 10 seconds has elapsed, the circuit mutes the speaker until the call in progress is over. No more will you have to listen to all of those dull, long-winded conversations just to be sure that you won't miss a call, and the circuit is automatically disabled when you need to get in on the conversation.

Circuit Details

The circuit uses the 0-to-4½-volt transition when the squelch opens in the Wilson 1402, as a trigger to set the timing in motion. This voltage is picked off the top of the end-mounted 6.8k-Ohm resistor which is directly above the LD 3030 audio driver IC on the printed circuit board. This makes all wiring connections available on the top of the board for ease in construction. The basic circuit design is that of a switching transistor with a timing circuit and an audio gate transistor tied to it.

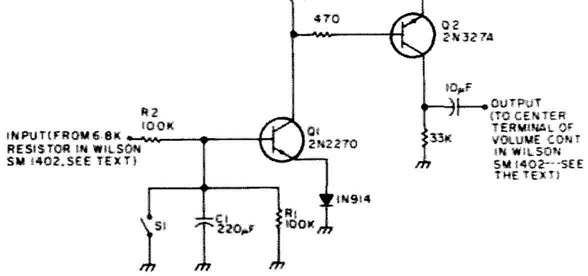

Fig. 1. Schematic of automatic muting circuit.

Circuit Operation

When the squelch opens, a voltage at the 6.8k resistor goes from 0 to around 4½ volts. This voltage is applied to the circuit to start charging the R1C1 combination through R2. As soon as about 1.2 volts is attained on the base of Q1, Q1 switches on which in turn switches on Q2. Q2 is provided as an audio gate, and also to isolate the timing switch from the audio switch. When Q2 is switched on, it gates the audio that normally would have been fed to the audio driver IC from the center tap (wiper) of the volume control pot to ground.

Anyway, I guess it goes to ground, since it works. It might be going through the batteries, but wherever it sends the audio, it effectively shorts whatever audio is available to operate the driver IC to ground and kills all the audio output from the speaker. This takes about 10 seconds for the choice of resistors and capacitors I used.

When the 1402's squelch closes, the voltage at R2 goes to zero and C1 is discharged through R1 until Q1 switches off, which switches off Q2 and restores the audio to a squelched receiver ready for the next call. This takes about 6 seconds for the values that I used. The measured current draw for this circuit is less than 1 mA, and if you are running the audio level fairly loud (volume control at ½ maximum or louder) the circuit also will function as a battery saver. This is because the circuit clips the audio on extended conversations to zero, which reduces the radio's current draw to that of minimum specs for unsquelched operation.

The switch S1 can be any kind of an SPST switch, but since I didn't want to drill a hole in the radio, I used a mercury tilt switch similar to the one in most residential wall-mounted heating thermostats which I found in my adequately-stocked junk drawer. The switch is positioned inside the radio so that when the radio is lying on a table, the switch is open and will let the capacitor, C1, charge. When the radio is picked up and held in the vertical handheld operating position,

the switch is closed, which holds capacitor C1 permanently discharged for the normal two-way operation of the radio.

Construction Hints

I built all the components in the area at the top of the radio around the volume and squelch controls. This was done with hard wiring since space is limited, and also since there really isn't much to wire. The largest component was the capacitor, and it fit nicely in the small recess beside the S-meter. The resistors were ¼-Watt jobs, and the mercury switch was one that I had which was larger than necessary, but fit nicely in the gap between crystals in the crystal deck. I adjusted the mercury switch so that the mercury ran away from the contacts when the radio was lying flat.

After connecting all the items as shown, the unit can be checked out by holding it in the horizontal position and breaking the squelch. After about 10 seconds, the audio will mute and will remain that way until the squelch is closed or until the unit is picked up and held in the vertical position.

In closing: An idea that I didn't try out, that came to me after I built the circuit, is to use a LED instead of the 1N914 diode which would give a visual indication of a muted radio. Also worth noting is that I tried several transistors for Q2, but found that with some, as soon as they were connected, a loss in the radio's audio occurred. This was not the case with the 2N327A, and I heartily recommend being careful of substitutes in this area. ■

Build a $5 Coax Switch

—why pay more?

$3.47 or $5.02.

Jerrold Swank W8HXR
657 Willabar Drive
Washington Court House
OH 43160

A two-way coax switch is a real convenience for switching between two antennas, or for grounding an antenna, or for switching one antenna to another rig. Take a small minibox, Bud #5A30005 or #5A3014, and with a 5/8" drill or a Greenlee punch cut three holes as shown in the drawing in Fig. 1. These are cut on the three sides of the U-section.

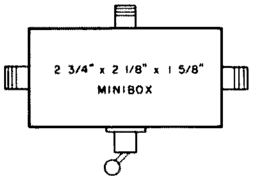

Fig. 1.

Mount three SO-239 connectors on the three sides of the U-shaped section. Then punch a ½" hole in the other section and mount a heavy-duty toggle switch—SPDT. I used a DPDT and strapped the two sections together to take heavier current.

Connect as shown in Fig. 2. Use a flexible piece of coax shield from RG-58/U for connection to the "common" connector so that the box can be put back together easily.

Use #12 wire or the center conductor from RG-8/U coax for the other connections.

The total actual parts cost was $5.02, saving about $35 over a commercial switch of the same type.

The same idea can be used without the toggle for an emergency T connector, by connecting all three SO-239s together. Cost: $3.47. ■

Hamdom's Evangelical Crusade

—born-again ops, arise!

I have given up trying to explain ham radio to my wife. And who can blame me? Last time I mentioned that something was wrong with my keyer, she called a locksmith. And how could I try to explain *that* to someone who thinks TVI is what you get when you sit too close to the television set?

So, I've decided to keep my thoughts in that area to myself. Except for the Tuesday-night gathering of hams at our place (at which my wife, by the way, chews us out for always talking about OSCAR but never having the courtesy to invite him over), I've pretty much regressed into a domestic ham fantasy-world.

Which is not all too bad, actually—it beats trying to explain the thrill of operating 160 meters to someone who thinks it's an Olympic running event.

Take last Thursday night, for example: The XYL and I, having finished the dinner dishes, had settled down for an evening of the all-American, middle-class, intellectual challenge—watching television, of course. I sat in the easy chair, fiddling with a 450 MHz handie-talkie, which my wife proudly tells her friends is "an expensive CB."

Like I said, who can blame me?

My wife had long since given up on what channel I want to watch, since I usually mumble something about "20 meters" (unless the band happens to be a total disaster, in which case I grumble something about "the gang on two"). So as I sat fiddling with a stubborn battery pack, she flipped to the "Billy Graham Crusade."

She settled herself on the couch and picked up her knitting. "Is that alright with you, dear?" she asked. "Mfgpht," I said. She went back to her knitting and I went back to my battery pack. Finally, I got the thing in place. I stuck an earplug in the jack, fiddled with the squelch control a bit, and then turned the channel selector to the local repeater. With that odd combination — Billy Graham in the right ear and some guy testing an autopatch in the left — I sat back in the chair and promptly fell asleep.

What was it that Freud said about people who were depressed by daylight — that all their secret thoughts revealed themselves in dreams? Anyway, the last thing I remember thinking is, "Wouldn't it be great if we had someone who could do the same thing for ham radio that Billy Graham is doing for religion?" Then, I had my first glimpse of a frustrated ham's vision.

Madison Square Garden. The Astrodome. The Hollywood Bowl. It didn't matter; the scene was the same every time. Hundreds of thousands of people stream into the nation's gathering places to learn about ham radio. CBers, SWLers, and even stereo freaks crowd the auditoriums and stadiums of the nation to hear the world's greatest spreader of the ham's way of life. Suddenly I awoke with a start, sat up in the chair, and said aloud:

"Ham. Elmer Ham."

My wife put down her knitting and stared at me quizzically. "What was that, dear?" she asked.

"Nothing," I said, and then I pointed to the handie-talkie. "Just thought I heard a friend of mine." I knew it was pointless to say any more, because trying to explain ham radio to my wife usually resulted in disaster. Last time I'd spoken of inductance in her presence, she'd called the Pentagon and begged them not to draft me.

She shook her head. "Honestly, dear. I'd swear all you ever think about is your silly little radios."

"Mfgpht," I said cheerfully. Before long I was asleep again, and the vision returned.

The Astrodome. Thousands pour into the stadium; millions more watch on television. Elmer Ham doesn't appear immediately, of course — they save him for the last while they warm up the audience. Maybe they will play tapes of rare DX QSOs over the stadium PA system, or have a choir chanting in CW — something like that. Ushers pass out Novice-class study guides as the curious throng floods through the doors; attendants begin circulating straight keys and antenna tuners throughout the audience as the stadium fills. And then Elmer Ham takes the stage.

He's a dynamic, charismatic man, and the audience responds enthusiastically as he extols the virtues of ham radio. An attendant in a white lab coat wheels up a cart full of equipment, and Elmer Ham goes through the rounds of explaining the mysteries of hamdom to a hundred thousand gaping neophytes. They "ooohhh" at SSTV. They "aahhh" at DX and RTTY. And they

The VBC Model 3000, the world's first and only narrow band voice modulation system is now a proven success. Leading communications engineers were enthusiastic about the NBVM system from the beginning. Now the idea of more QSO's per kilocycle has fired the imagination of Amateurs everywhere. The benefits of this advanced communications system are being demonstrated all over the world.

For present VBC users we can provide a list of other happy owners. For those Amateurs, who have not experienced NBVM yet, "why not add your name to the list?"

The VBC Model 3000 provides full audio level compression and expansion... complete intelligibility in only 1300 Hz bandwidth. It permits you to take full advantage of other stations' RF speech clippers and processors... similar to the amplitude compression and expansion used for many years in telephone and satellite communications.

The Model 3000 is for mobile and fixed station use and requires no modifications to your existing equipment. It is completely self contained, including its own audio amplifier. The unit automatically switches into transmit mode when microphone is keyed or voice operation is used. It connects just after the microphone on transmit and just prior to the speaker on receive. In addition to its basic function of operating in a narrow bandwidth, the Model 3000 also increases the performance of your station in the following ways:

- Reduces adjacent channel interference
- Increases signal to noise ratio
- Increases communications range

Some of its outstanding features include:

- High quality narrow band speech
- Self contained transmit/receive adapter
- Built in audio amplifier
- 5 active filters with a total of 52 poles
- Rugged dependable hybrid IC technology
- Low power consumption

Receive only features, such as sharp voice and CW filtering and amplitude expansion, provide improved reception without requiring a unit at the transmitting station.

For the more advanced experimenter the Model 3000 is available in a circuit board configuration for building into your present transceiver.

Henry Radio is ready to offer technical assistance and advice on the use and servicing of the Model 3000 and will help introduce new owners to others operating NBVM units. Get in on the ground floor... order yours now.

Price: VBC Model 3000 $349.00
Circuit board configuration $275.00

For more detailed information please call or write. The Model 3000 will be available from most Tempo dealers throughout the U.S. and abroad.

"wowww" as Elmer effortlessly copies CW at 65 wpm.

After a good hour, he makes the big pitch: Would anyone in the audience be interested in obtaining a ham license? Thousands raise their hands. Elmer warns them that they'll be required to learn their code and theory, that the battle won't be won without a little study and dedication. Some of them are afraid, but others have made up their minds that they're going to do it—and at Elmer Ham's invitation, they flock down to the stage where attendants sign them up for code and theory courses.

"Beautiful," I said aloud. Then I opened one eye. Billy Graham had been pre-empted by some commercial about a lady plumber, and my wife was still working at her knitting. And, of course, the gang was still jabbering away on the local repeater.

"What happened to Elmer Ham?" I asked.

"Who?"

"Billy Graham. I meant Billy Graham."

"Oh, him. He's all over, and you missed the best part. It was so exciting," she said.

"I know." I continued to fiddle with the handie-talkie until the next program—a rerun of "I Love Lucy"—hit the air.

"This all right with you?" my wife asked methodically.

"Mfgpht," I said, and settled back into the easy chair. This one, I mused, would require a little more thought. How about a Cuban bandleader who keeps in touch with his crazy redheaded wife through 2 meters? Hmmmm . . . ■

The Memorizer Flies Inverted

—something Yaesu never told you

The popular Yaesu FT-227R Memorizer presented me with a hidden capability one evening. I had always envied those who could instantly "go inverted" with one flick of some super-switch thoughtfully provided by some brilliant designer. It was a great pleasure to discover that this was an unspecified option in my own transceiver! It was even more fun to think that I had discovered something that even the designers on this unit hadn't thought of.

This operating procedure, which requires no physical modifications at all, causes the transceiver to exchange 600-kHz-offset transmitting and receiving frequencies with one click of the function switch. It is accomplished by using a not-obvious combination of control settings which is not mentioned in the instruction manual.

The following steps specify how to memorize the lower frequency, set to the higher frequency, energize the memory recall, and utilize the MEM and +600 positions of the function switch.

1. Release M (Memory) and MR (Memory Recall) switches.
2. Set the frequency display to the *lower* of the repeater input and output frequencies.
3. Press M switch.
4. Set the frequency display to the *higher* of the repeater input and output frequencies.
5. Press MR switch.
6. Set function switch to the MEM or +600 position.

The frequency display now indicates the receiving frequency. Choose the frequency you want to listen to, the repeater input or output. When the transceiver transmitter is keyed, the output frequency will be offset 600 kHz *up* or *down* as required to effect the desired operation.

For normal operation on repeaters with a low-side input frequency, use MEM. In this position, the transmitter is forced to be the memorized (lower) frequency and the MR switch function is defeated so that the received frequency (higher) is what is set into the dial. When you set to the +600 position to go inverted, the MR becomes effective so that the memorized (lower) frequency is recalled and the transmitter is offset up by 600 kHz.

For normal operation on repeaters with a high-side input frequency, use +600 and switch to MEM to go inverted.

As long as the memorized frequency is not lost, the transceiver can be used on other frequencies with any offset you want and returned to this special mode by following steps 4 through 6.

If you have to ask what this type of operation is good for, I'm surprised you have read this far. In truth, I don't know of much practical use unless your favorite repeater frequently goes off the air due to timeout failure. At least it is fun to be able to use all of the capability of the equipment.

See you on the output—direct! ■

Double-Duty Decoder Project

—listen to SCA and tune in RTTY

Geoffry W. Kufchak
WA1UFE/5
159 Ashford
San Antonio TX 78227

Here are two projects that I've had in mind for a long time. Since they are very similar in design, I am combining them into one article divided into two parts. Part One covers the SCA decoder, and Part Two covers the FSK decoder.

Part One

For a long time I have been wanting to receive the background music that many FM stations broadcast. I had read several construction articles describing decoders, but they were all too complicated. I wanted something simple and easy to build. I knew that a 565 PLL could be used to decode SCA broadcasts, so out came the *Signetics Data Book*. A schematic shown in Fig. 1(a) is included, along with the specifications on the IC. Another schematic (Fig. 5) demonstrated that FSK decoding is possible. Since the two circuits were very similar, I designed a printed circuit board to permit constructing either circuit by installing the appropriate parts.

SCA is uninterrupted background music transmitted by some FM stations for use in offices and commercial businesses such as department stores. The SCA signal is on a 67-kHz subcarrier of the regular FM channel, and is only ten percent of the total signal. The subcarrier is frequency-modulated, and has a bandwidth of plus and minus 7 kHz.

An input signal greater than 50 mV is required by the 565 to be able to operate properly. A resistive voltage divider is used to establish the correct operating bias for the inputs, and a high-pass filter is used to attenuate the regular FM channel audio. The 67-kHz operating frequency of the 565's vco is set by the RC constant of R6 and C3. The vco requires only approximate tuning, as it will lock over a range of plus and minus 30 percent. However, a test point is provided so that the vco may be set exactly with a frequency counter. A low-pass filter and de-emphasis network is formed by resistors R7, R8, and R9, along with capacitors C6, C7, and C8. This filter removes most of the bias that usually accompanies the SCA signal.

The audio output from the 565 is approximately 30 to 50 mV and may be fed into your receiver's stereo demodulator. Most receivers today utilize an IC as a stereo demodulator and can distinguish between mono and stereo signals. A mono signal lacks a 19-kHz pilot signal, and the demodulator will automatically apply the same audio to both output channels. Coincidentally, these ICs also require about 50 mV of audio signal at the input. Most of these ICs also include the proper de-emphasis network for the regular FM signal.

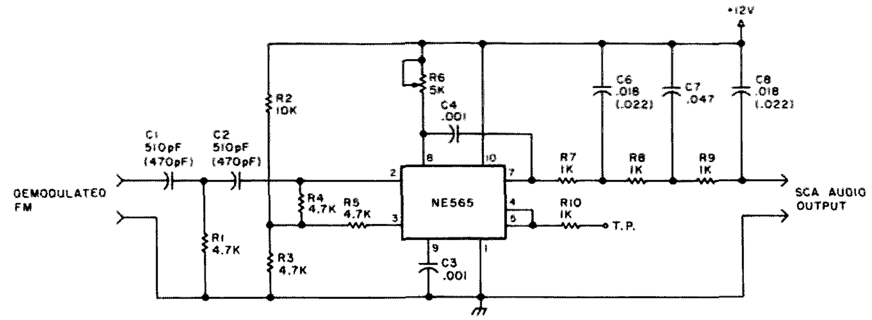

Fig. 1(a). Schematic of SCA decoder. Values in ( ) are acceptable substitutes. Adjust R6 for 67 kHz at TP.

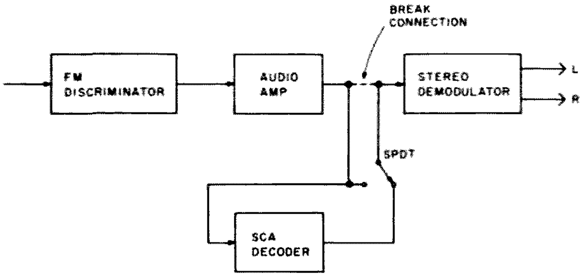

Fig. 1(b). Typical connection for decoder.

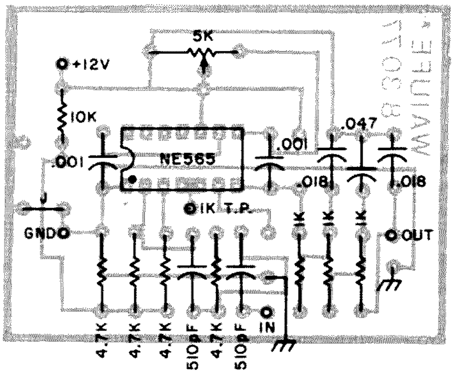

Fig. 2(a). Parts layout of decoder.

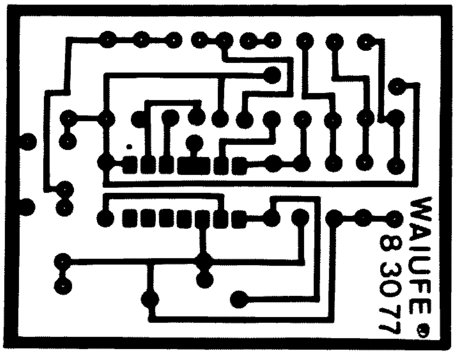

Fig. 3. SCA/FSK decoder board. Board is 2" x 2½". Foil side view.

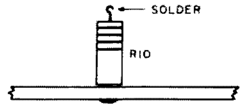

Fig 2(b). R10 TP. Mount vertically and form top lead into a loop.

The input of these ICs is usually preceded by a transistor-amplifier whose input comes from the receiver's discriminator. This signal contains both the SCA audio and the FM multiplexed audio. The demodulator normally eliminates the audio signal above 50 kHz. Fig. 1(b) shows a typical connection scheme for installing the SCA decoder. It may be to your advantage to obtain the schematic for your receiver to locate the proper connection point.

I installed an SPDT switch so that I could alternate between the regular channel and the SCA signal. This also makes it easy to locate a station in your area that transmits SCA. Just tune to each station, and flip the switch. It may be necessary to increase the volume control due to the low level of the SCA signal.

Use ¼-Watt 5% resistors and Mylar™ capacitors, except for C1 and C2, which may be disc type. If you have difficulty obtaining exact values, acceptable substitutes are noted in parentheses. These are the values I used, and I encountered no trouble in the operation of the decoder.

Also, use shielded audio cable if the decoder is to be mounted more than a couple of inches away from the tie-in point. This will reduce the possibility of hum being picked up and amplified. Power consumption is about 8 mA, so a power switch should not be needed. Just find a point in your receiver where you can obtain +12 volts and wire the decoder to it.

Part Two

The FSK decoder is a little more difficult because of the dual power supply requirement. Both plus and minus 5 volts and 12 to 15 volts are needed. Fig. 9 shows a schematic for a suitable power supply.

Fig. 4(a) shows an audio processor stage to supply an approximate 50 mV signal to the input of the 565. These two amplifiers have a gain of .1, so you'll need more than 500 mV of audio input. You should be able to tap off from your receiver's headphone jack.

Fig. 4(b) is the digital processor stage. The signal from the 565 output and reference is applied to IC2a which buffers the signal. The output from this amp is a distorted square wave. IC2b further conditions the signal, and the 200k potentiometer is adjusted for a 3-volt peak-to-peak signal at TP1. IC3 converts this signal to a clean square wave. Pin 3 of IC3 should be set at −.2 volts for proper symmetry of the output signal. However, this is only an approximate setting. Due to differences in components, it may be necessary to align this stage.

There are two methods of aligning this stage. The first requires the use of a general-coverage receiver capable of tuning RTTY signals. Start by tuning in a good strong FSK signal. Try one of the RTTY net frequencies. Connect the output of the decoder to the keying circuit of your page printer, and be sure that the printer is set properly for the speed of the signal being received. Use a high-impedance voltmeter between pin 3 of IC3 and ground, and adjust the resistor while watching the printer for the best copy. Take note of the reading for future reference.

The second method is for all you purists who have everything. You will need: frequency counter, oscilloscope, square wave generator with variable baud width and amplitude controls, and a voltage-controlled sine wave generator with amplitude control.

Set the sine wave gen-

For Figs. 4(a), 4(b): IC1, IC2—uA747, 14-pin DIP. Pins 9, 13 — +15 V, pin 4— −15 V. IC3—uA741, 8-pin DIP. Pin 7— +15 V, pin 4— −15 V.

erator to a frequency of 2550 Hz and 500 mV or more output. Adjust the square wave generator for 11 ms bauds. The output of the square wave generator goes to the voltage control input of the sine wave generator. Set the square wave generator for positive output only, and adjust the level to bring the frequency of the sine wave generator to 2975 Hz. Switch to negative output only, and adjust the level for a frequency of 2125 Hz. Recheck the positive level again, and adjust, if necessary. Switch the square wave generator back to square wave output. The output from the sine wave generator should now read 2550 Hz—or close to it. Using the scope on pin 6 of IC3, adjust the potentiometer for equal positive and negative baud widths. The board should now be aligned, and operate properly with FSK RTTY signals.

Fig. 5 is the schematic for the FSK decoder. Note the differences in values for the change in operating frequency. Use ¼-Watt 5% resistors and Mylar capacitors here, also. R6 sets the vco frequency to 2550 Hz for 850-Hz shift RTTY. This circuit is capable of decoding down to 150 Hz shift, although for narrow shift

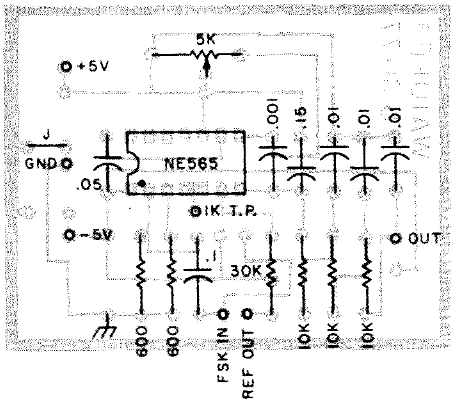

Fig. 8(a). Parts layout for FSK decoder.

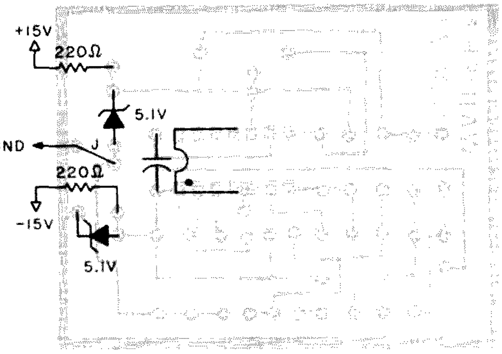

Fig. 8(b). Alternate layout for use with ±15 V supply only. Mount 220Ω resistors vertically.

RTTY, it may be necessary to add a 10k resistor between pins 6 and 7 of the 565. This will narrow the lock range, and improve the tracking of the vco. Always tune the vco for a frequency halfway between the upper and lower limits of the signal you wish to decode, with no input applied to the decoder.

Choose the zener diode at pin 6 for the output voltage required for your application. For TTL circuits, use a 1N751, 5.1-volt zener. A 1N757 will give you 9 volts.

I haven't tried it yet, but it would seem that if the FSK decoder is tuned to 1800 Hz, it may operate for decoding audio tapes using the Kansas City Standard of 1200-2400 Hz. If it does, tape decoding for microprocessors is possible, and that makes this a three-in-one project.■

Santa Maria CA 93454

Build a Simple HT Charger

—doubles as a 12-V supply

When I acquired my Standard handie-talkie in 1972, I went all out—leather case, rubber ducky, mini mike, fistfull of crystals, and a shiny black charger.

The SCH HUC1 charger was prone to losing its filter capacitors (bad lot or something) without giving any indication of malfunction except that a full charge would last only a few hours. Since Standard chose to use a voltage quadrupler circuit, that loss required four new 100-uF capacitors.

Recently, I bought a Heathkit 2 meter 10-Watt amplifier for use with the handie-talkie on trips and in rental cars. The amp takes about 100 mA in transmit. I decided to build a 12-volt two-Amp power supply in the charger case and replace the charger circuit with one of the new three-terminal regulators in a constant current mode.

The circuit is easy—all the parts are available at the friendly neighborhood Radio Shack. When you open the charger, take *everything* out. The slide switch is too big with the new transformer in place and you have to drill some holes anyway, so take everything out and drop the remains in the junk box. You will use only the line cord and the cabinet. The chassis is the S-shaped piece of steel surrounded by the outside shell.

I used banana jacks ¾ of an inch apart for output terminals and a small piece of P-type vectorboard to hold the small parts. If you use the existing switch hole for one end of the transformer, there is just enough room for the two 1000-uF filter capacitors to be crammed lengthwise against the transformer frame. There is not much room, but underneath the capacitors, is a five-terminal phenolic terminal strip bolted to the other mounting hole of the transformer. This terminal strip holds the four-terminal bridge rectifier, the positive ends of the filter capacitors, provides a ground contact, and connects the secondary of the power transformer.

I tried to use a 12-volt rms transformer, but, with only 2000 uF in the filter, the output voltage under load drops to about 8 or 9 volts. Using a higher voltage transformer allows the regulator circuit to handle the ripple dynamically, since the dc instantaneous value never drops below 14 volts.

Output ripple under load was measured at under 30 millivolts; no hum is detectable without instruments on the rf carrier. The pass transistor is bolted to the bulkhead inside the charger case. Install it with a mica washer and be sure that there is no short between the collector and the case. Note the fuse in the schematic for short-circuit protection. It

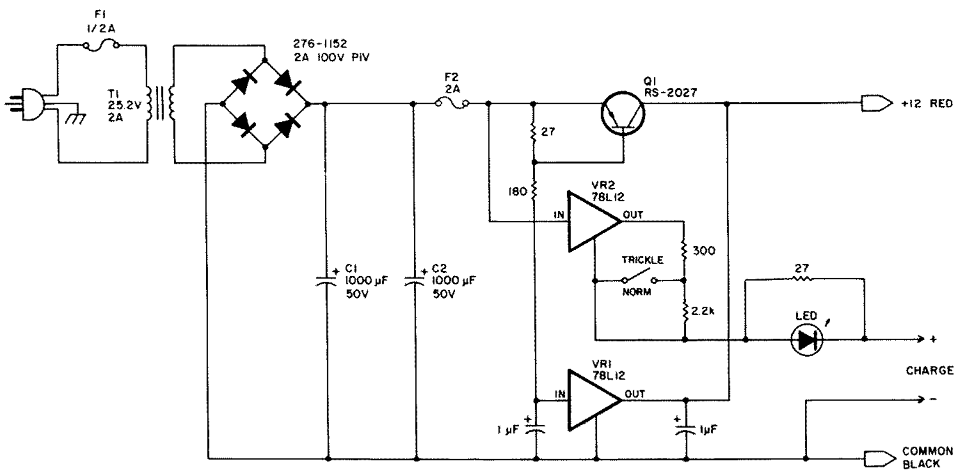

Fig. 1.

was hard-wired into the lead from the bridge to Q1, and its ends were covered with tape.

Because the open circuit charging voltage is over 25 volts, be *sure* your handie-talkie's external power jack is wired so that the nicads are always connected to the charger pads and disconnected from the radio power bus when the external jack is plugged in.

The constant-current regulator, VR2, maintains the regulator voltage across the series resistance. To find the resistance value for any constant current within the regulator's power range, divide the regulator voltage by the desired constant current.

With the switch in the normal charging position, the regulator delivers a constant 43 mA (just like the Standard circuit was supposed to) even into a short circuit with no ill effects. I connected two battery packs in series and the current was still just 43 mA. The LED gives positive indication of charging current—43 mA will never hurt the nicads. The trickle-switch position reduces the charge current to around 7 mA and is used when the handie-talkie gets only infrequent use. The 27-Ohm resistor across the LED shares the current in the normal charge mode to prevent burning out the LED. In the trickle mode, not enough current is left to illuminate the LED. The normal/trickle switch is installed in one of the rivet holes from the old slide switch; the LED is spot-epoxied into the other rivet hole.

I now have a charger I'm sure of and a utility 12-volt supply as well! ■

Do-It-Yourself Carrying Case for Wilson HTs

—save $14.88

I'm the proud owner of a new Wilson Mark II HT,

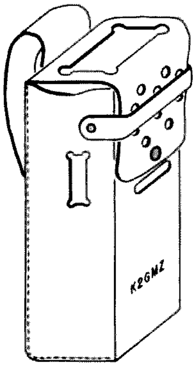

Fig. 1. Instamatic camera case—after surgery.

which I had the good fortune to win at the 1978 Syracuse hamfest. This little gem came complete with .52-.52 xtals, rubber ducky antenna, and a wall charger for the nicad battery pack.

The first thing I did, after I came down to earth, was to fire off an order to a *73* advertiser for crystals for several local repeater frequencies.

Next, I needed a carrying case. Ouch. The Wilson (no relation, unfortunately) leather case lists at $18.95. Seemed like an extravagant outlay for a case to carry around an HT which merely cost me the price of a dollar raffle ticket!

An alternative which came to mind was, "Can a nearsighted, middle-aged ham with two left hands consisting of ten thumbs cut out and sew a leather or vinyl case which would have enough class to house this fabulous HT?" The painfully obvious answer to this question was a resounding "No!"

While wandering through the camera department of a local discount department store (K-Mart), I spotted a top-grain cowhide leather Instamatic-type camera case which had the exact dimensions I needed. Cost? $4.07 plus sales tax.

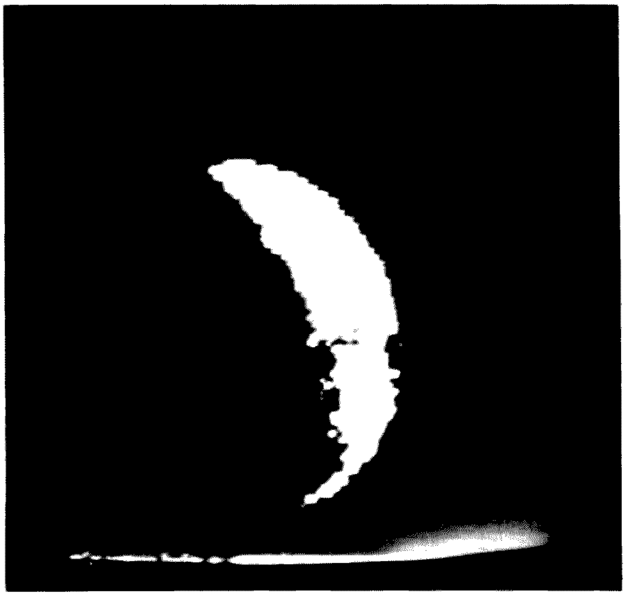
A few minutes worth of surgery using an X-acto knife as a scalpel, and *voilà*, a case which could compete with the high-priced spread. In addition to the openings shown in Fig. 1, I punched a hole in the bottom which allows me to plug in the charger without having to remove the unit from the case. ■

Come On In—
The Viewing Is Fine

—an update on trends and developments in SSTV

Dave Ingram K4TWJ
Eastwood Village, #1201 South
Rte. 11, Box 499
Birmingham AL 35210

The interest, excitement, and technical advancements affecting the fascinating world of slow-scan TV during recent times have been a phenomenal experience. Newcomers and old-timers alike are enjoying the pleasures of visual communications as this amateur frontier continues expanding on an unlimited basis. While some operation-minded amateurs are visually sharing their lives and interest with SSTVers thousands of miles away, others are diligently pursuing new developments—many of which may be perfected before this article appears in print. This enthusiasm, devotion, and progress are prime indicators of the sheer fun awaiting all amateurs seeking new communication horizons.



Voyager II, *150,000 miles from Earth, looks back and acquires this crescent-shaped view of home. This picture was transmitted on 20-meter SSTV by Dick K6SVP.*

As an updating account, this article will describe some of the latest happenings in SSTV.

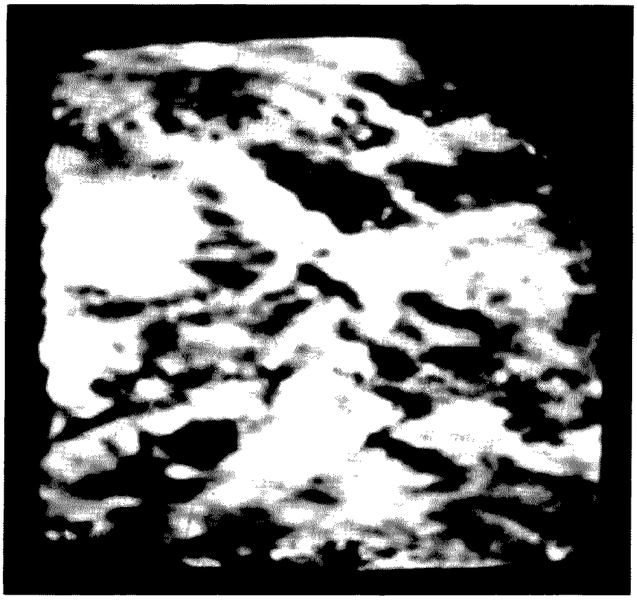
If you are thinking of joining our ranks, if you're a newcomer to SSTV, or if you haven't been overly video-active, this information should update you on recent innovations. Possibly, this article will send you racing back to the shack, anxious to share in the fun of slow-scan TV activity.

Trends and Innovations

Large numbers of SSTV newcomers continue to grace the airwaves, and their popular choice of gear is the Robot 400 system. Home-brew scan converters have dwindled in popularity due to their complexity and high cost, compared with the Robot or Thomas Engineering units. While the cost-per-bit of memory chips is somewhat expensive as this article is being written, a substantial change is expected in the near future. Indeed, the introduction of single memory chips capable of 65,000-bit storage may soon open new possibilities for inexpensive and compact home-brew scan converters.

Surprisingly, the interest in digital scan converters hasn't created a large open market for used P7 SSTV gear. While many slow-scanners retain their P7 equipment when progressing to a digital scan converter, others sell their P7 gear directly to an awaiting SSTV newcomer. The recent interest in medium-scan TV appears to be another major reason for continued P7 monitor popularity.

This W6VIO-retransmitted view of Jupiter shows multiple layers of ammonia ice crystal clouds surrounding the planet. The shadowing effect of the sun prevents full view of Jupiter. The phenomenal "red spot" is visible in the lower right of the picture. This view was obtained with a 1500-mm telescope aboard Voyager II. *The spacecraft was approximately 50 million miles from Jupiter at the time.*



View of Jupiter's atmosphere in an area not far from the noted "red spot." This picture was acquired by Voyager II *on March 5, 1979, and also retransmitted by W6VIO during their March "Commemorative" operations.*

Many slow-scanners consider using their freed equipment for this new 10-meter frontier.

Interest in SSTV keyboards appears to be declining, compared with a couple of years ago. Likewise, lengthy transmissions of pure text are being replaced by actual in-shack scenes and operator views. This aspect definitely indicates the ability to use SSTV rather than just prove that "the box works."

A second SSTV net recently began operating on 14,230 kHz, and its support has been extremely good thus far. This net begins at 2330 GMT each Thursday night. Net Controls are Tom N7AON and Stan WD4DCW. The prime objective of this net is providing technical assistance and SSTV newcomer guidance. A large number of fascinating SSTV pictures is exchanged during each net session, so that Thursday nights are becoming a very exciting time for all active SSTVers.

DX SSTV Drive

During the latter part of 1978, word was received in the United States of the extreme enthusiasm of two outstanding DX stations to operate SSTV. These stations were Tom Christian VR6TC, of Pitcairn Island, and VK9RH, of Norfolk Island. Soon thereafter, an appeal was introduced, both on the air and via magazine articles, and gear for both stations was acquired. The concern and support among slow-scanning amateurs is a phenomenal situation! As this information is being written, donors of SSTV equipment for VR6TC and VK9RH desire to remain anonymous. Their reasons for anonymity are quite simple: The donors do not desire special considerations of prima donna titles.

The *Yankee Trader* left Florida en route to Pitcairn during February, 1979. A part of the vessel's cargo was a Robot 400 system, complete with camera and monitor. Soon thereafter, a Robot 70 and 80 system was shipped to VK9RH on Norfolk Island. The Northern California DX Foundation assisted in this operation. Truly, this DX SSTV drive was one of amateur radio's most outstanding accomplishments during 1979.

Extremely close view of Jupiter's "red spot" reveals a boiling storm with electromagnetic radiation equivalent to several atomic bombs.

MSTV

An expanded frontier of SSTV development which is rapidly gaining widespread popularity is in the area of medium-scan TV. Essentially, the concept of MSTV permits limited-motion, long-distance TV

Classic picture of Jupiter's moon, Io, in front of the gigantic planet. That's Jupiter's atmosphere in the background. This was one of the most popular pictures relayed by W6VIO.

Jupiter's moon, Ganymede, as viewed by Voyager II *from 1.6 million miles away and retransmitted on 20-meter SSTV by W6VIO.*

communications in a 35-kHz frequency spectrum. This limited motion is accomplished through the use of scanning rates which are faster than slow-scan but slower than fast-scan. Special Temporary Authorization has been granted to several amateurs to allow their medium-scan TV transmissions on the high end of 10 meters. Any amateur with appropriate equipment may join the fun of viewing these transmissions. Don Miller W9NTP, of Waldron IN 46182, is spearheading this project. Additional supporters and STA stations include WØLMD, W3EFG, W6MXV, and WB9LVI.

During early 1979, the first phase of medium-scan TV swung into action. W9NTP placed a beacon transmitter on 29,150 kHz to check channel communications capability. The beacon was reliably received throughout North America and Europe, thus ensuring that a medium-scan TV signal could successfully be utilized on the 10 meter high end. As this information is being written, the second phase of medium-scan TV is approaching initiation. This phase will involve using modified P7 SSTV equipment for medium-scan TV operation. Ultimately, the P7 gear will be replaced with microprocessors and digital scan converters designed to the established MSTV parameters.

Modifying conventional P7 slow-scan gear for medium-scan TV requires a reasonable amount of experimentation, but the final results make all effort definitely worthwhile. Medium-scan TV will use a 5-field-per-second interlaced format with a horizontal line rate of 317 Hz. These sync signals must trigger a monitor's sweep driver circuits, which in turn must produce a MSTV raster. The horizontal ramp-generating capacitor must thus be decreased in value by a factor of 317/15 while the vertical capacitor must be changed from 1/8-field per second to 5 fields per second. The SSTV monitor's front end should be bypassed, and the approximately 20-kHz video signal should be wideband-amplified to an appropriate level and applied to the cathode ray tube. The previous concept should prove successful for modifying Robot or W6MXV P7 monitors for medium-scan TV operation.

The final phase of medium-scan TV development will consist of replacing P7 gear with converted digital scan converters and microprocessors. This phase will bear a close resemblance to the present scan converter evolution with SSTV. The medium-scan project is a rigorous undertaking, and success isn't absolutely guaranteed. True amateur spirit and widespread dedication are two essential ingredients which need additional emphasis at the time this report is being written.

The Voyager Spacecrafts and SSTV

Alert and sharp-eared SSTVers have some exciting times in store for them during future months and years. Members of the Jet Propulsion Lab Radio Club have been providing "ringside seats" during high points of the *Voyager* space mission, and views thus far have been fantastic. This deep space mission began during August, 1977, and it is projected to continue until approximately late 1986. A brief outline of the events of *Voyager I* and *Voyager II* are as follows.

Voyager II was scheduled to fly by Jupiter during July, 1979. As *Voyager I* passes Jupiter, a slingshot effect hurdles it on toward Saturn. Its estimated flyby of Saturn will be during August, 1981. During this pass, *Voyager I* will move to within 2500 miles of Titan, Saturn's largest moon. Titan is the only one of Saturn's moons which has an appreciable atmosphere. Assuming everything is then progressing

successfully, *Voyager I* will continue toward Uranus. Its estimated time of flyby is January, 1986.

Voyager II was approaching Jupiter as this report was being written, and the views were truly breathtaking. Most *Voyager* and/or JPL activity is on 14,235 or 28,680 kHz. The usual times of operations are during weekends and early evening hours. The JPL club station call is W6VIO (W6 Viking In Outerspace). Don't miss the upcoming views!

Looking Forward

A number of technical and operational advancements are due to affect the SSTV world favorably during the near future, and now is the opportune time for amateurs to prepare for these exciting times. Several SSTV contests, QSO parties, etc., are being planned, while on-the-air slow-scan activities are also beginning to reflect progressive ideas and personal interests.

AMSAT's Phase III satellites also should provide some unique SSTV capabilities, provided all satellite operators discipline their operating techniques. EME, transequatorial propagation, and packet radio communications are some other examples of future horizons which, if combined with data compression techniques, can provide unlimited video capabilities.

If you would like to fully renew your interest in amateur radio, try the fascinating frontier of slow-scan television. The cost of visually equipping an existing setup is truly negligible compared with the unlimited pleasures it affords.■

Rack 'Em Up

—glass jars and orange crates are "where it's at" for parts storage

Over the years, many methods have been described for storing parts, including just about everything from shoe boxes to old tin cans. Perhaps, though, most popular is the ordinary food jar. The common jar is great as a parts container since it has a lid, is transparent, is easily available, and is inexpensive. Now, I use old jars to store my parts which I don't use too often, and while that is not too interesting, I feel that the method of storing these jars is.

A favorite way of storing jars full of components is to place them standing up on a shelf, but that has a couple of disadvantages. If you have a deep shelf and a number of rows of jars, the problem is that it is hard to see what is in the jars in the back, and you have to remove the front rows in order to get at those in the back. To alleviate this situation, you could have only one row of jars, but then you use up a lot of wall space with your jars. The solution is rather simple. When you put your jars on the shelf, lay them on their sides. That way, you can just slide out the jar you want. As for the problem of identification, you can put a label on the top of the jar. If you actually want to see what's in the jar, just put it on the shelf backwards so you can look through the bottom.

Now for some details on what I'm using. For jars, I've got tall and narrow iced-tea jars, with a rated capacity of 13 ounces. For the shelves, I'm using old orange crates stacked on top of each other. These crates are about 8″ × 11″ × 6″ and they're just about perfect for my jars. I can fit two rows of four jars and another row of three jars in there and there's just a bit of wasted space in the top two corners. I used what I had on hand but it shouldn't be too hard to throw together some sort of box for your jars. Don't make your boxes too big, since the jars might have a tendency to roll around. Also, I'd suggest that when you're picking your jars, find something which is tall as compared to its diameter.

So that's the story. The jars in their box sort of remind me of wine bottles in their rack. When you pull out a bottle from a bottom layer, the top layers drop down, so keep a hand on the jar immediately above the one you're taking out. Now, isn't that better than a bunch of old tin cans?■

Gadzooks! A Variable 0-260 V Ac Supply!

—junk-box delight

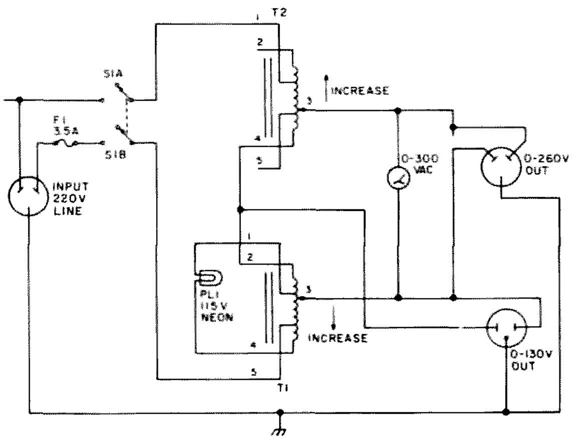

Fig. 1. Variable 0-260 volt ac supply.

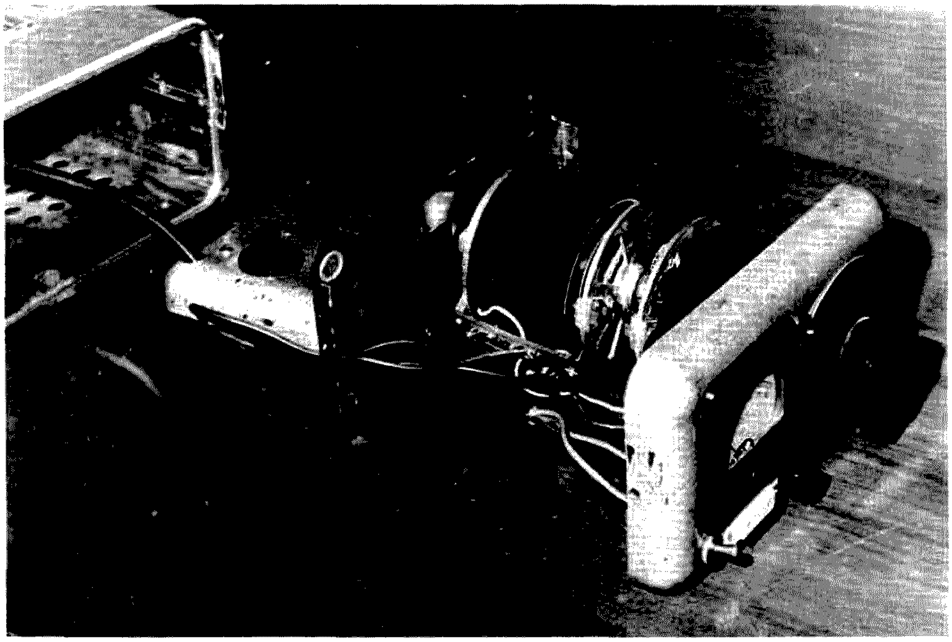
William P. Winter, Jr.
WB8JCQ/LU1AKO
530 College Ave.
Ashland OH 44895

Need and the lack of money are the parents of home brew, it seems—at least in my case. I had a need to test plate transformers for power output under varying load conditions. I was trying to test various 220-volt primary transformers which were available to me for use in a linear amplifier. I had a 0-150 volt, 500-Watt supply which I used with a 110-220 volt auto transformer, but things began to saturate at about 700 Watts.

It occurred to me that two variable transformers hooked up in series might do the trick. I knew that I had tucked back in the junk box two Ohmite VT-4 rotary transformers which had come out of a piece of $2.50 surplus I had picked up years ago. I had long since used much more value than that in diodes, connectors, chassis, and cabinet, so the rotary transformers were just lying there for free.

I checked them out with clip leads to make sure everything worked OK. Then back to the junk box; out came a 0-300 volt ac meter of unknown origin, a large vibrator inverter supply which had long since given up the ghost, plugs, receptacles, switch, fuse holder, and a pilot light. Inspection showed that everything would fit snugly inside the old inverter cabinet. A few hours of work resulted in a nice in-



strument capable of more than 1000 Watts intermittent output.

The schematic (Fig. 1) shows the hookup and terminal numbers for the Ohmite units I used. Other models may be different. The two units must be coupled mechanically back to back. In my case it was necessary only to loosen the shaft setscrews and slide the shafts back enough to couple the two shafts together. I drilled out an old shaft coupler to fit the two shafts, then mounted a sheet metal support on the other end to support the rear transformer. The pilot light was hooked between 115-volt fixed taps, and a 0-130 volt output was taken from one of the variable transformers.

It should be noted that the hooking back-to-back is the only way to get one transformer to rotate clockwise (looking from the front) and the other to rotate counterclockwise. Otherwise, a set of gears would have been necessary. It can be seen from the schematic that the slider on T1 goes down to increase voltage output as the slider on T2 goes up to increase voltage output. If the two transformers were hooked up in tandem, the sliders would only track back and forth with a fixed 110-volt output.

Need a variable 220-volt supply for connecting to the 220-volt line? Can't find one available at a cost you are willing to pay? Do as I did and have the satisfaction of home-brewing something not too complex—and the best bonus of all for me was the cost—$0.00. You can't beat that! ■

Scrounger's Special: Used Dental Tools

—your DDS throwaways make dandy PCB drills

J.E. Corwin WA7OYX
1511 E. Third Street
Mesa AZ 85203

Did you ever get to the middle of a PC project and find one of the holes too small to accept that end of tinned stranded wire? Or that square LED lead? Did you then get out your trusty drill and bit and proceed to accidentally damage either the PC board or a component or both?

If so, dear reader, perhaps your friendly dentist can help you.

Over the past years, I have paid out to my dentist about as much as I have contributed to the IRS welfare and pension funds, and have thus been able to help him maintain his private airplane and a pair of matched quarter horses. Dentists, like most people, are more than willing to explain what they are doing and how the procedure is performed. As a result of a recent visit and the usual question and answer session, my dentist gave me a set of conventional root-canal reamers he had discarded for no longer being sharp enough to be used on human teeth.

Root-canal reamers are similar to the familiar twist drill, come in various diameters, and have a knurled knob at the top end to permit the reamer to be twirled with the fingertips. The set given to me (in a plastic box about the size of a book of matches) contains six reamers, sized from about 1 mm to 2 mm. The reamer shanks are 1" long and the knurled knobs are 1/2" long by 1/8" in diameter. It is a simple matter to select the proper size reamer and enlarge the PC hole to accommodate the wire or component with just a few twirls of the fingers—and without damage to other components, PC board, or foil.

The next time you see your dentist, ask him to save his throwaways—they do come in handy around the shack. ■

First Look at Latest Radio Laws

Route 9, Box 279
Sour Lake TX 77659

1. All rules and regulations are printed in reverse order. They should be read from right to left for maximum comprehension.

2. Any section of Part 97 conducive to good operating procedures will be changed on the next FCC docket.

3. The FCC encourages all amateurs to improve their skills toward the goal of being allowed to operate in the 27.405-28.000-MHz band.

4. Propagation characteristics of HF signals are influenced mainly by the distance (in meters) between the transceiver and the nearest wall.

5. Propagation forecasts may be ignored, as they are formulated by those who understand the subject.

6. Minimize interference to other services by disconnecting the microphone (or key) from the transmitter. Note that in some cases, additional shielding may be required.

7. Wideband F3 emissions are not allowed below 50 MHz.

8. Wideband F3 emissions are not allowed above 50 MHz.

9. Average power is 1.5 times unmodulated power, which is 4 times the modulating power (1.717x) as related inversely to PEP/average ratio of 2 to 1 or 4 to 1, as the case may be.

10. Resistors and inductors are identical, and those of like values may be interchanged (see Ohm's Law). Capacitors react inversely and must be installed backwards.

11. Ohm's Law is an unproven theory which changes, depending on whether one reads *QST* or *73*. Note: *QST* takes the conservative view.

12. In ACs (audio circuits), black wires must be connected to black wires and red wires must be inductively coupled to red wires of the same gauge.

13. Circuits oscillate because of insufficient neutralization of tuned circuits. This leads to degeneration of the entire circuit. Such a condition may be prevented by careful adherence to #12 above.

14. Vacuum tubes are sacred instruments of the gods and should not be adjusted internally under any circumstances.

15. Transistors (and ICs) are instruments of the devil and should be left alone.

16. Semiconductor diodes are the source of many electronic problems, as they pass current in only one direction.

17. Toroidal inductors create a magnetic field and are very useful in picking up small items dropped into the rig. In normal operation, these devices attract metal. By reversing the leads (and thus the magnetic field), plastic and mica are attracted.

18. Resonant circuits in rf amplifiers cause a hollow, tinny sound in the transmitted signal. Key clicks may also be observed if a scope is attached.

19. The transmission line must be of a length sufficient to reach from the rig to the antenna. Insufficient length leads to nonresonance and reduced signal output.

20. If an antenna stays up, it is too small. (This information was obtained from other sources and is subject to personal verification.)

21. The oscilloscope is valuable in observing radio phenomena such as wavelength, resistance, impedance, and the size of the outer conductor.

22. "You can't work 'em if you can't hear 'em." (Illustrates the need for a receiver in all shacks.) ■

The Induction Relay: Self-Powered Switching

—this unusual actuator doesn't require a separate control voltage

Waldo T. Boyd K6DZY
P. O. Box 86
Geyserville CA 95441

A standard relay requires a separate source of low-voltage current to pull in the armature, usually supplied by either a step-down transformer or a low-voltage dc supply. There's an interesting and potentially very useful way of controlling remote equipment without need for a separate low-voltage source: The induction relay.

An induction relay is particularly appropriate when a mechanical function such as opening a detent is needed.

In Fig. 1, a laminated core, such as an old transformer "E" core, is wound with the main or primary winding on one outside leg. The other outside leg is sawed off and used as the armature. A secondary winding of a few turns of heavier wire is placed around the center leg of the "E" to form the control winding.

The primary winding is connected across the 115-V supply line. With the control winding open, the primary winding induces a magnetic flux that flows through the path of least magnetic reluctance, the center leg of the "E", leaving the armature unaffected. When the remote switch shorts the control coil, the major portion of the flux shifts to the longer circuit path that includes the armature, pulling it in to close that magnetic circuit. Thus, only a minimum holding current flows through the control winding and external switch circuit.

The value of the open-circuit voltage is not important, but can be determined easily since it bears the same relationship to the source voltage as the turns-ratio relative to the primary. In essence, the signal transformer is incorporated in the relay itself.

Variations of remote control may be had by substituting mechanical linkages for the relay contacts, or by using both.

Representative winding data might be, for instance, 400 turns no. 26 or 28 for the primary, and 50 turns no. 18 for the control winding. Actual numbers are not critical, and minimum needs are a function of core cross-sectional area. However, the number of primary turns required would be roughly one and one-half times the number on the original transformer primary winding because the core area is reduced when the primary winding is transferred from the center of the "E" to the end. If all the original primary wire is rewound onto a smaller coil form, the number of turns will come out just right.

In the example above, the control voltage would be about 14 volts, open circuit, just right for a no. 18 bell wire pair, provided the run (distance from relay to shorting switch) is not excessive.■

The Further Adventures of Keycoder

—simplified wiring for the toroidal cores

In the July, 1976, issue of *73 Magazine*, there was an article about Keycoder I, a Morse code generator using a typewriter-style keyboard. This article by WA9VGS caught my eye. I had seen other circuits in the past, but this one seemed simpler. Besides, I'd just about had it with paddles and electronic keyers. I tried single paddles, dual paddles, finger keying, dot memories, dash memories, iambic, etc. Even with the Accu-Keyer,[1] I made too many mistakes.

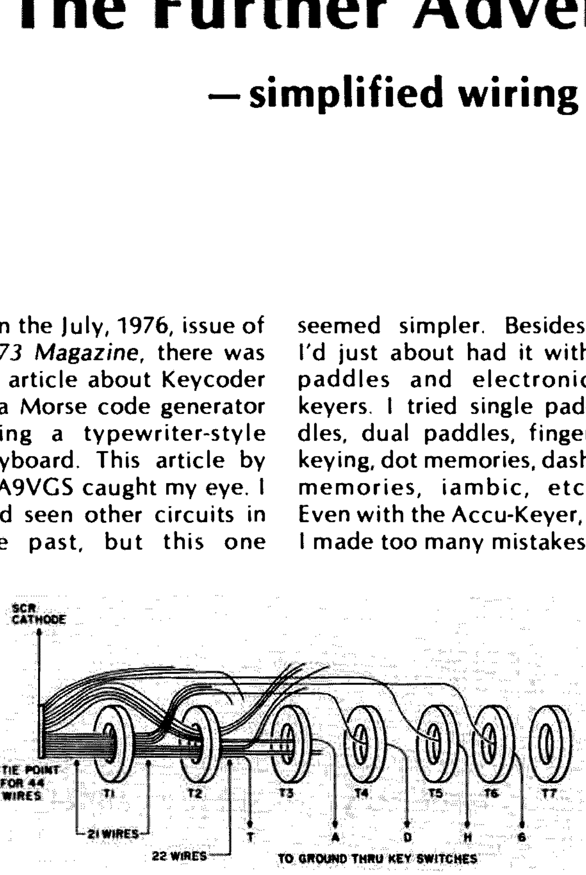

Fig. 1. Typical wiring. Note that only five characters are shown here, for simplicity.

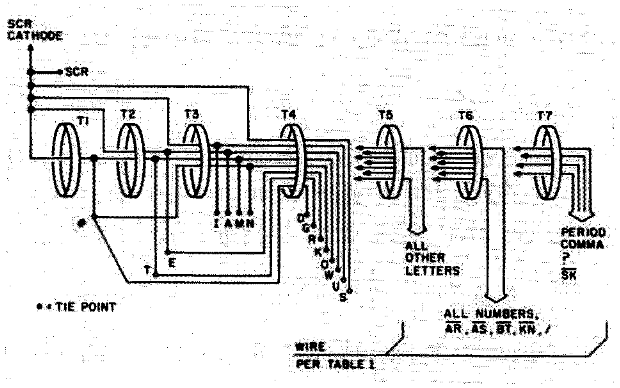

Fig. 2. Eliminate unnecessary duplicate wiring with tie-points. Follow Table 1 to complete the wiring.

So this would be the answer.

Let me point out that progress is very slow in my ham shack, and, so, the October, 1976, issue of *73 Magazine* arrived. Here was another article by WA9VGS describing a CMOS version of the Keycoder I. This one was still simpler; no power supply was needed—just a 9-volt battery. I was determined to build one!

By late 1978, I got around to it! I built not just one (with a few modifications, of course), but several more, for friends. Two other friends, AB9J and WB9ROU, also built them. We all think they are the greatest.

Since just about everyone is familiar with the aforementioned Accu-Keyer, a comparison is in order: The Accu-Keyer takes 7 ICs plus an ac power supply, miscellaneous parts, and a fairly expensive paddle; the CMOS Keycoder takes 7 ICs, miscellaneous parts, a 9-volt battery, and a keyboard. A new keyboard can be obtained for about the price of a paddle. But even surplus, used, or homemade keyboards will give excellent results. So, for less than the cost of an Accu-Keyer, you can have a code typer. Keyboards should become very popular for CW even for those who don't own computers.

Now, if I've convinced you to build a code typer, here are some ways to simplify the keyswitch wiring. Whether you build the

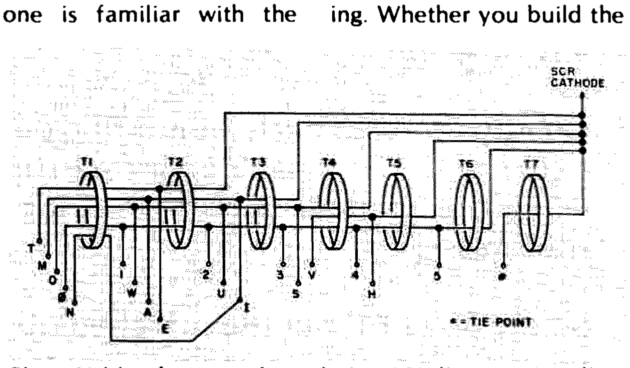

Fig. 3. Wiring for opposite polarity (SCR line at T7). Follow Table 2 to complete the wiring.

TTL or CMOS version, or any other using five to eight toroidal transformers, these principles can be applied.

First, to refresh your memory, keyboard encoding is done with the very simple but clever idea of passing wires through toroidal cores. This idea has been around so long I forget where it originated. Each core has a secondary winding of about ten turns which sets (or resets) an associated flip-flop when a wire passing through the core (the primary) is pulsed. A wire going outside the core has no effect.

Phasing Is Important

The pulses produced on the secondaries must be the correct polarity for your circuit. Phasing (or polarity) of windings can be determined experimentally during construction. Some designs may have enough "ringing" in their secondary circuit that they will work either way. My circuit boards were built with T1 on the left and T7 on the right. My SCR line was brought out just to the left of T1. Each keyswitch wire was started at the SCR line and run toward T7, passing through and outside the proper cores to encode that particular letter, and then run directly to the corresponding keyswitch. This was not difficult with #30 magnet wire, but resulted in as many as 23 wires going through some cores.

Simplification

By using tie-points for some or all of the characters, it is possible to reduce the number of wires considerably: one wire through T1, two wires through T2, four wires through T3, and eight wires through T4. If you put a connector between the circuit board and the keyboard, the connector terminals can be the tie-points. Looking at the original wiring table, or Fig. 1, it is seen that about 21 wires pass through T1. These could all be tied together between T1 and T2 with no change in operation—so replace them with just one wire! The bundle of wires passing through T2 (about 22) can be broken into two groups: One group came through T1, and the other group came around T1 from the SCR tie-point. So, only two wires are needed passing through T2. By the same logic, only 4 need pass through T3; 8 through T4. By the time you get to T5, the saving is still 4 wires.

Fig. 2 shows the pre-wiring, using tie-points for 14 characters. Notice that tie-point "#" is not a character but just a tie-point designation. This pre-wiring can be done with plastic insulated wire. That means a lot less scraping of magnet wire. Table 1 lists the routing of the remaining wires. These may go to additional tie-points or directly to the corresponding keyswitches.

I would advise you to get your complete circuit board wired and operational before starting the keyswitch wiring. Keep power on the circuit and have a sidetone oscillator connected to the output. This allows you to check each wire before soldering to be sure it produces the correct character. It also will show up any mistakes in my list as well as printer errors (such confidence!), and it gives you the last check on correct phasing.

Now, if your phasing is reversed or you wish your SCR line to enter from the T7 end, Fig. 3 shows pre-wiring for 18 characters. Route the remaining wires according to Table 2.

My hope is that this article will encourage many of you to build code machines and that my wiring will make it just a little easier. ■

All About Ground Rods

—getting connected to Mother Earth

Ground rods are usually used in amateur installations for grounding purposes related to lightning protection. However, they are also the only choice one may have when using a short vertical antenna which requires a good ground. The use of buried radials is certainly preferable to establish a ground screen for a vertical antenna, but an elaborate radial system may require more space than is available, or it may be impossible to lay down such a screen because of obstacles. Usually, vertical antennas are used because of space restrictions. Having the best ground for them, even if it is only a grounding rod, cannot help but improve their efficiency.

Whatever the application one may have for ground rods, it is useful to take a detailed look at how they work. The effectiveness of ground-rod usage can vary widely depending on how they are installed, and sometimes a few simple measures can vastly improve their performance.

Basic Principles

One of the basic factors affecting ground rod performance is the nature of the soil in which it is placed. The relative resistance of a ground connection using a ground rod can vary from 2 Ohms in a clay-type soil to over 2700 Ohms in a very sandy soil. As shown in Fig. 1, it is mainly the resistivity of the soil closest to the ground rod, however, that determines the overall effectiveness of the ground connection. Ninety percent of the total grounding effectiveness is determined by the soil characteristics within a radius of about 6 feet around the ground rod.

There is nothing one can do about the nature of the soil in a given location, of course, but a general awareness as to whether the soil has a high clay content, is a mixture of moist clay and sand (loam), or is mostly sand and gravel, will act as a general guide for the elaborateness needed for an effective ground rod installation.

The moisture present in a given soil can have a marked effect on its resistivity. Fig. 2 gives an illustration of this for common red clay soil. Note how sharply the resistivity increases when the moisture content of the soil falls below 20%. Again, in reality, there is not much one can do to control this factor, but it is useful to be aware of it since, depending on seasonal rainfall conditions, the effectiveness of some ground connections using ground rods can vary widely.

Temperature is another factor influencing ground rod performance. Offhand,

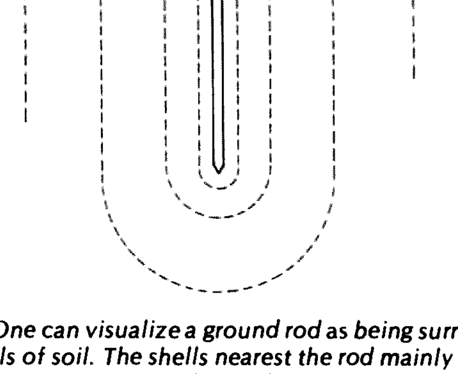

Fig. 1. One can visualize a ground rod as being surrounded by shells of soil. The shells nearest the rod mainly provide the rod's connection to the earth.

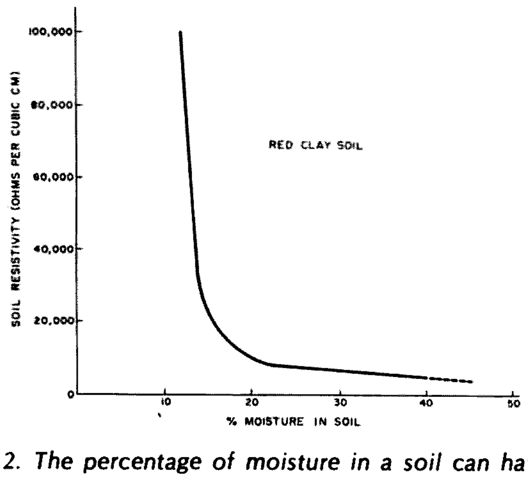

Fig. 2. The percentage of moisture in a soil can have a significant effect upon its resistivity.

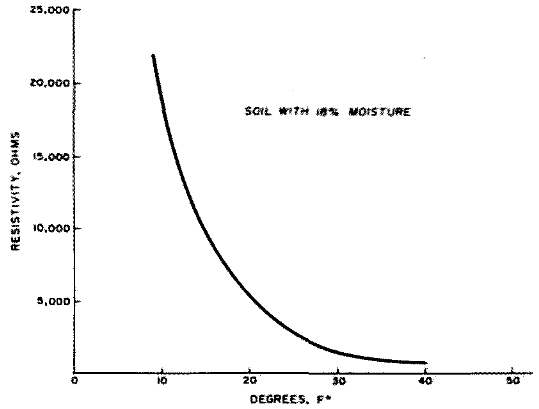

Fig. 3. Temperature also can have a sharp effect on soil resistivity.

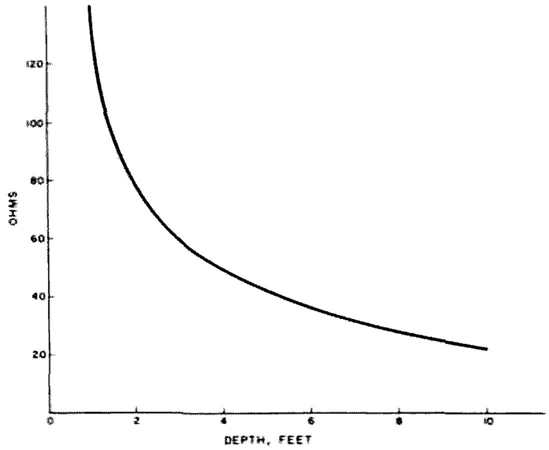

Fig. 4. Ground connection resistance for a single ground rod driven to different depths.

one might be inclined to think that the colder it gets, the better the ground rod should perform, since we associate coldness with rain or snow. The opposite is true, however, when just cold temperatures are considered. When the earth freezes to any depth, the water in the soil freezes, moisture is lost, and the resistivity of the soil increases. Fig. 3 shows the sharp effect decreasing temperature can have on soil resistivity. So, again, seasonal weather changes regarding temperature can severely affect ground rod effectiveness in some localities which suffer severe cold seasons. About the only preventive measure one can take is to drive the ground rod below the frost line whenever possible.

The depth to which a ground rod is driven also is important, as shown in Fig. 4. This illustration shows the calculated ground connection resistance with regard to the depth of a ground rod, under what might very broadly be termed "average" soil conditions. The illustration assumes uniform moisture and soil resistivity at all depths. In reality, soil resistivity usually decreases with depth since the few feet near the surface are subject to alternate wetting and drying, depending on rainfall, while the moisture content of deeper soil is more stable. For ground rods more than a few feet long, therefore, performance is usually better than that indicated by Fig. 4.

The greatest reduction in ground connection resistance is obtained by driving a ground rod to between 6 and 8 feet down. Although there may be particularly moist soil conditions in certain locations and at certain times of the year where a 3-foot rod is effective, this generally is not the case. Note also that the illustration is based on a ground rod fully driven into the ground. Many casual ground rod installations leave from ⅓ to ½ of the rod's length above the surface of the soil.

Finally, another factor that one might consider is the diameter of the ground rod used. Intuitively, one would think that the larger the diameter of the ground rod used, the better the earth connection. As it turns out, however, diameter plays a negligible role in improving the ground connection. This has been confirmed by various tests done by the former Bureau of Standards and the Underwriters Laboratories. Whether one uses a ½", 1", or even larger diameter rod can be based on mechanical strength factors, therefore—that is, a size large enough to be driven into a particular type of soil without bending.

The metal the rod is made out of is not important except for the factor of corrosion. Steel rods are commonly used, although if one can obtain Copperweld grounding rods, they are ideal for the purpose. They have a steel core for strength and an exterior of copper for corrosion resistance.

Measuring Grounding Resistance

It is not necessary usually to measure the actual grounding resistance provided by a ground rod as long as good practices are used in installation of the rod. If one is curious about the approximate grounding resistance achieved, however, it can be measured fairly easily by the three-point method shown in Fig. 5. In this illustration, A represents the actual ground rod and B and C represent two temporary ground rods of two- to three-foot lengths. The temporary rods should be placed about 6 feet from the actual ground rod and from each other. The resistances between rods are measured and used in the formula shown to obtain the grounding resistance of rod A. One can try doing the measurements with an ohmmeter, but usually bet-

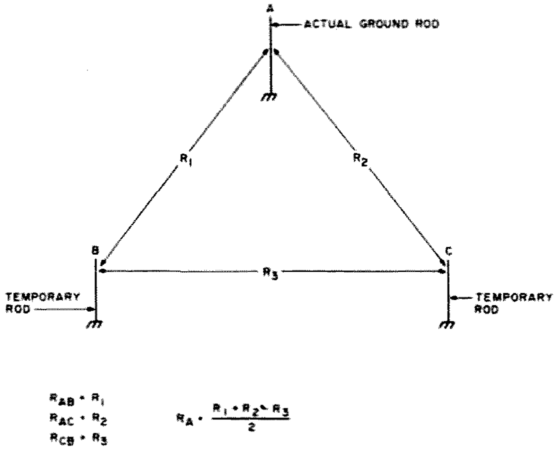

Fig. 5. By installing two temporary ground rods and taking some resistance readings, one actually can measure the ground connection resistance of a ground rod.

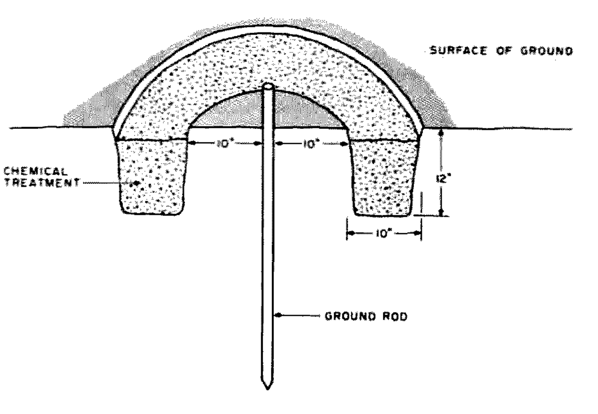

Fig. 6. Construction of a trench around a ground rod to hold a chemical treatment. The rod should be at least six feet into the ground, although the treatment will improve the performance of shorter rods also. Dimensions are not at all critical.

ter results are obtained if one goes the old-fashioned voltmeter/milliammeter route, using some low voltage ac or dc as a voltage source.

Improving Ground Rod Performance

There are several methods one can use to improve ground rod performance if it is felt that a simple ground rod installation is inadequate. One of the simplest methods is to use multiple ground rods. If the rods are spaced 6 to 10 feet apart, they act very much like resistances in parallel. So, two rods will effectively cut the ground connection resistance in half, and so on. It is very important to maintain the spacing between the rods.

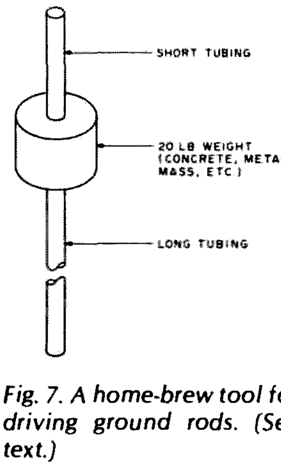

Fig. 7. A home-brew tool for driving ground rods. (See text.)

A few rods clustered closely together will be no more effective than a single rod. A practical maximum number of rods to improve a ground connection by the use of multiple ground rods probably would be 4 to 6.

The ground lead from each rod should be run directly to the base of the vertical antenna in the center of the ground rod array. There should also be one directly underneath the base of the antenna to act as a central ground rod. There might be some value also to running interconnecting wires between adjoining ground rods, but this is not as important.

Another fairly simple method to improve a single or multiple ground rod installation is to treat the area around the rod chemically, as shown in Fig. 6. This is not complicated to do since one does not have to dig a very deep trench around the rod. The treatment material can be magnesium sulphate, copper sulphate, or even ordinary rock salt. All are about equally effective; the only advantage of magnesium sulphate is that it is the least corrosive.

Note that the treatment material does not have to touch the ground rod—nor should it. With the passage of time, the treatment material will seep towards the rod and corrode it, however, and rain will wash it away. The result of all this is that within a period of perhaps 2 to 3 years both the rod and the treatment material may have to be replaced. On the other hand, one accomplishes quite a bit by using chemical treatment. Typically, a ground connection resistance of over 1000 Ohms can be lowered to less than 100 Ohms.

Another method to improve ground rod performance that is useful in some cases is to drive the rod particularly deep. This method probably doesn't have much applicability when an antenna ground is considered, since it is soil resistivity and grounding nearer the surface that mostly affects antenna performance. Also, it is naturally hard to accomplish in many soils without specialized equipment. Nonetheless, in some soils, particularly sandy ones which start to have a clay base further down, it can be very effective from the viewpoint of lowering the ground connection resistance. For example, by using a 20-foot sectionized ground rod as compared to a 6-foot one, the resistance might be reduced by a factor of 6 or more.

Installing Ground Rods

Any number of methods of installing ground rods have been devised, and this is pretty much an area where one's own ingenuity has to come into play. The sledgehammer approach will suffice in a great many cases. Another method which some amateurs have found successful with hollow tubing used as ground rods is to insert a garden hose in the tubing and let the water pressure wash away the soil slowly as the tubing is pushed into the ground.

Another approach to consider, especially if one is going to drive several rods, is to construct a simple home-brew driving tool such as is shown in Fig. 7. This tool is made around a central weight mass of about 20 pounds. A short piece of tubing is affixed on one side and a longer piece of tubing on the other side. The tubing is chosen so that it is just large enough to slip over the ground rod. The length of the two sections will depend on the length of rod—three- and one-foot sections, for instance, are used for a 6-foot ground rod. In use, the long end of the tool is slipped over the ground rod and used initially to pound the rod into the ground. As the rod gets driven further in, the short side of the tool is slipped over the rod and used to complete pounding the rod into the ground. The advantage of this tool is that the tubing over the ground rod prevents the rod from bending, and the pounding force exerted by the tool is exactly in line with the axis of the ground rod.

Ground Rod Connections

All the effort exerted in placing a ground rod can be wasted if a dependable low-resistance connection is not made to the rod. The ideal case would be to have all metals the same: a copper-plated rod using a copper clamp and copper wire. Such items and fittings can sometimes be purchased through electrical contractor supply houses. In most cases, however, one will be using dissimilar metals for the rod, clamp, and ground wire. In this case, one must be sure only that all connecting surfaces are clean and tight. Covering the clamp and rod junction with some weatherproofing compound also would be advisable. ■

OSCAR Orbits

Courtesy of AMSAT

The listed data tells you the time and place that OSCAR 7 and OSCAR 8 cross the equator in an ascending orbit for the first time each day. To calculate successive OSCAR 7 orbits, make a list of the first orbit number and the next twelve orbits for that day. List the time of the first orbit. Each successive orbit is 115 minutes later (two hours less five minutes). The chart gives the longitude of the day's first ascending (northbound) equatorial crossing. Add 29° for each succeeding orbit. When OSCAR is ascending on the other side of the world from you, it will descend over you. To find the equatorial descending longitude, subtract 166° from the ascending longitude. To find the time OSCAR 7 passes the North Pole, add 29 minutes to the time it passes the equator. You should be able to hear OSCAR 7 when it is within 45 degrees of you. The easiest way to determine if OSCAR is above the horizon (and thus within range) at your location is to take a globe and draw a circle with a radius of 2450 miles (4000 kilometers) from your QTH. If OSCAR passes above that circle, you should be able to hear it. If it passes right overhead, you should hear it for about 24 minutes total. OSCAR 7 will pass an imaginary line drawn from San Francisco to Norfolk about 12 minutes after passing the equator. Add about a minute for each 200 miles that you live north of this line. If OSCAR passes 15° east or west of you, add another minute; at 30°, three minutes; at 45°, ten minutes. Mode A: 145.85-.95 MHz uplink, 29.4-29.5 MHz downlink, beacon at 29.502 MHz. Mode B: 432.125-.175 MHz uplink, 145.975-.925 MHz downlink, beacon at 145.972 MHz.

OSCAR 8 calculations are similar to those for OSCAR 7, with some important exceptions. Instead of making 13 orbits each day, OSCAR 8 makes 14 orbits during each 24-hour period. The orbital period of OSCAR 8 is therefore somewhat shorter: 103 minutes.

To calculate successive OSCAR 8 orbits, make a list of the first orbit number (from the OSCAR 8 chart) and the next thirteen orbits for that day. List the time of the first orbit. Each successive orbit is then 103 minutes later. The chart gives the longitude of the day's first ascending equatorial crossing. Add 26° for each succeeding orbit. To find the time OSCAR 8 passes the North Pole, add 26 minutes to the time it crosses the equator. OSCAR 8 will cross the imaginary San Francisco-to-Norfolk line about 11 minutes after crossing the equator. Mode A: 145.85-.95 MHz uplink, 29.4-29.50 MHz downlink, beacon at 29.40 MHz. Mode J: 145.90-146.00 MHz uplink, 435.20-435.10 MHz downlink, beacon on 435.090 MHz.

FCC

Reprinted from the Federal Register.

Amateur Radio Service; Modifying Procedures for Notifying the Commission of Name and Mailing Address Changes; and To Give a 5-Year License Term to All Licenses Issued

AGENCY: Federal Communications Commission.

ACTION: order.

SUMMARY: The Commission amended §§ 97.13 and 97.47 to delete provisions which allowed Amateur licensees to notify the Commission of name and mailing address changes by letter. All future Amateur license modifications must be requested by filing the appropriate application form. The Commission also amended § 97.59 to provide that all Amateur licenses will be given a five-year term.

DATES: The effective date of the Order is November 12, 1979.

ADDRESSES: Federal Communications Commission, Washington, D.C. 20554.

FOR FURTHER INFORMATION CONTACT: Maurice J. DePont, Private Radio Bureau, (202) 254-6884.

SUPPLEMENTARY INFORMATION:

Order

Adopted: September 27, 1979.
Released: October 5, 1979.

By the Commission: Commissioner Lee absent.

In matter of amendment of §§ 97.13, 97.47 and 97.59 of the Commission's rules.

1. Sections 97.13 and 97.47 of the Commission's rules set forth the procedures to be followed by amateur licensees who wish to renew or modify their amateur radio license. In each instance, the request must be made by submitting an FCC Form 610 (or 610-B in the case of a club or military recreation station) to the Commission's office in Gettysburg, Pennsylvania. However, these rule sections also provide that a change in the licensee's name or mailing address may be accomplished by notifying the Commission by letter.

2. The provision concerning notification by letter has apparently led to confusion on the part of many amateur licensees and has *unnecessarily increased the* workload of the Commission's application processing staff. Most letter requests for address change fail to specify that it is only the licensee's mailing address which has changes. Therefore, the staff is required to ascertain whether or not the station location has also changed. In the majority of cases, the station location has indeed changed. In such a situation, § 97.47 requires a formal modification of the license. Therefore, it is necessary that the licensee file an application.

3. In order to eliminate the confusion among amateur licensees as to when an application need be filed, and to lessen the burden on the processing staff, the Commission is amending §§ 97.13 and 97.47 to delete the provisions concerning letter notice. Henceforth, all amateur license modifications must be requested by submission of the appropriate application form.

4. The Commission is also amending § 97.59 to provide that modified licenses will be issued for a five-year term commencing on the date of the modification. Currently, that section provides that modified licenses shall bear the same expiration date as the license being modified.

5. Since the amendments herein ordered are procedural in nature, they are excepted by Section 553(b) of the Administrative Procedure Act from the requirement of prior public notice and comment.

6. Accordingly, it is ordered, effective November 12, 1979, that Part 97 of the Commission's rules is amended as shown in the Appendix attached hereto. Authority for this action is found in Sections 4(i) and 303 of the Communications Act of 1934, as amended.

7. For further information on these rule changes, contact Maurice J. DePont, 254-6884.

(Secs. 4, 303, 48 stat., as amended, 1066, 1082 (47 U.S.C. 154, 303))

Federal Communications Commission.

William J. Tricarico,

Secretary.

Appendix

Part 97 of Chapter I of Title 47 of the Code of Federal Regulations is amended as follows:

§ 97.13 [Amended]

1. In § 97.13, paragraph (e) is deleted.

§ 97.47 [Amended]

2. In § 97.47, paragraph (c) is deleted.

3. Section 97.59 is amended to read as follows:

§ 97.59 License term.

(a) Amateur operator licenses are normally valid for a period of five years from the date of issuance of a new, modified or renewed license.

(b) Amateur station licenses are normally valid for a period of five years from the date of issuance of a new, modified or renewed license. All amateur station licenses, regardless of when issued, will expire on the same date as the licensee's amateur operator license.

(c) A duplicate license shall bear the same expiration date as the license for which it is a duplicate.

Ham Help

I would like to meet other amateurs who are avid bridge players. Perhaps we could form a net and discuss bridge hands, conventions, tournaments, and the possibilities for bridge-playing computer programs over the air. I am an experienced tournament player, but would be happy to talk to anyone interested.

Mike Marmer KB8GH
2749 Symphony Way
Dayton OH 45449

I'm a disabled amateur and could really use some help with the following:

1. I need someone to use my acetate film and their transfers, lines, etc., to make negatives from which I can expose sensitized PC boards myself. Any layout from my specs would be acceptable; their name, call, or whatever can go on the board.

2. I also need manuals for the BC-1306, RT-70, and VRC-19. I especially need a "Surplus Schematic Handbook" to copy. It is black with red letters and a white schematic on the front.

3. I am looking for a Knight-kit signal tracer (circa 1960) with an rf-af probe.

4. I also need someone to construct projects, at cost or a little over, from my diagrams and their/my parts.

John C. White WB6BLV

Social Events

Listings in this column are provided free of charge on a space-available basis. The following information should be included in every announcement: sponsor, event, date, time, place, city, state, admission charge (if any), features, talk-in frequencies, and the name of whom to contact for further information. Announcements must be received two months prior to the month in which the event takes place.

HAZEL PARK MI
DEC 2

The Hazel Park Amateur Radio Club will hold its 14th annual swap & shop on December 2, 1979, from 8:00 am to 2:00 pm, at the Hazel Park High School, Hazel Park, Michigan. Admission is $1.00 at the door, and main prize tickets are also $1.00. There will be food, plenty of free parking, and door prizes. Featured will be computer demonstrations of the Apple II, PET, TRS-80, and more. Talk-in on .52 simplex. For information, send an SASE to the Hazel Park Amateur Radio Club, Robert Numerick WB8ZPN, 23737 Couzens, Hazel Park MI 48030.

LORAIN OH
DEC 8

The Northern Ohio Amateur Radio Society will hold its annual Christmas banquet on Saturday, December 8, 1979, at Gargus Hall, Lorain, Ohio. There will be many excellent door prizes and an RCA TV, Regency scanner, and liquor prizes will be given away at a benefit raffle (tickets are $1.00). Tickets for the banquet are $9.00 and available on an advanced-sale-only basis. The deadline is December 6, 1979. Talk-in on 146.10/.70. For tickets and complete details, send check or money order to NOARS, PO Box 354, Lorain OH 44052.

SOUTH BEND IN
JAN 6

A hamfest swap & shop will be held on January 6, 1980, at New Century Center, on US 31 by the river, South Bend, Indiana. Tables are $3.00 each. Food service, automobile museum, and art center are in the same building as the hamfest. Talk-in on 146.52/.52, .13/.73, .34/.94, 147.99/.39, .87/.27, and .69/.09. For information, write the Repeater Valley Hamfest committee, Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616, or phone (219)-233-5307.

RICHMOND VA
JAN 13

The Richmond Frostfest III, sponsored by the Richmond Amateur Telecommunications Society, will be held Sunday, January 13, 1980, at the Bon Air Community Center. There will be a home-brew contest with four awards: most original idea, best electrical work, best mechanical work, and most deserving work, and prizes. FCC exams start 10:00 am and completed Form 610s must be received in the Norfolk Office of the FCC at 870 North Military Highway, Bank of Virginia Bldg., Norfolk VA 23502, no later than January 9th. Admission is $3.00, indoor flea market tables are $3.00, and tailgaters are $2.00. Talk-in on .28/.88 and .34/.94. For further information, contact the Richmond Amateur Telecommunications Society, PO Box 1070, Richmond VA 23208.

SHARON PA
JAN 19

The third annual Mercer County Amateur Radio Club seminar will be held at the Holiday Inn, West Middlesex, Pennsylvania, off I-80, from 9:00 am to 5:00 pm. Come to hear speakers on your favorite amateur radio topics. Advance admission is $2.00. There will be door prizes. For further details, write K3LA, PO Box 673, Sharon PA 16146.

ARLINGTON HEIGHTS IL
JAN 27

The Wheaton Community Radio Amateur Club will hold its Wheaton Hamfest Portable Nine on Sunday, January 27, 1980, at the Arlington Park Expo Center, Arlington Heights Race Track, Arlington Heights, Illinois. Doors will open at 8:00 am sharp! 300 free flea market tables will be available, plus 100 commercial booths. There will also be hourly door prizes. Tickets are $3.00 at the door and $2.00 in advance. For information, send an SASE to WCRA, Box QSL, Wheaton IL 60187.

LIVONIA MI
FEB 17

The Livonia Amateur Radio Club will hold its 10th anniversary Swap 'n Shop on Sunday, February 17, 1980, from 8:00 am to 4:00 pm, at the Churchill High School, Livonia, Michigan. There will be plenty of tables, door prizes, refreshments, and free parking available, plus reserved table space of 12-foot minimum. Talk-in on 146.52. For further information, send an SASE to Neil Coffin WA8GWL, c/o Livonia Amateur Radio Club, PO Box 2111, Livonia MI 48150.

DAVENPORT IA
FEB 24

The Davenport Radio Amateur Club will hold its ninth annual hamfest on Sunday, February 24, 1980, from 8:00 am to 4:00 pm, at the Davenport Masonic Temple, Highway 61 (Brady Street) and 7th Street, Davenport, Iowa. Tickets are $2.00 in advance; $3.00 at the door. Tables are $3.00 each, no limit, with a $2.00 additional charge for ac electrical hookup. Talk-in on 146.28/.88 WØBXR repeater. Advance tickets can be purchased by writing to club treasurer Clarence Wilson WAØOEW, 1357 W. 36th Street, Davenport IA 52806.

LANCASTER PA
FEB 24

The Lancaster Hamfest will be held on February 24, 1980, at the Guernsey Pavilion, located at the intersection of Rtes. 30 and 896, east of Lancaster, Pennsylvania. General admission is $3.00, except children and XYLs. Doors will open at 8:00 am. All inside spaces are available by advance registration only and are $3.00 each for an 8-foot space, which includes a table. There will be free tailgating in a specified area outside, if the weather permits. There will be a two-hour Dutch Country tour by an advance registration of $4.00. Food will be served at the hamfest. Also, there are excellent restaurants and accommodations in the area. Talk-in on .01/.61. For information, write Sercom, Box 6082, Rohrerstown PA 17603.

STERLING IL
MAR 9

The Sterling-Rock Falls Amateur Radio Society will hold its 20th annual hamfest on Sunday, March 9, 1980, at the Sterling High School field house, 1608 4th Ave., Sterling, Illinois. Advance tickets are $1.50; door tickets are $2.00. Over $2,000 worth of prizes will be given away. A large indoor flea market will be restricted to radio and electronic items only. There will be plenty of free parking, lots of bargains, and plenty of good food. Talk-in on .25/.85 (WR9AER). For tickets, write Don Van Sant WA9PBS, 1104 5th Avenue, Rock Fails IL 61071.

VERO BEACH FL
MAR 15-16

The Treasure Coast Hamfest will be held on March 15-16, 1980, at the Vero Beach Community Center, Vero Beach, Florida. Featured will be prizes, drawings, and a QCWA luncheon. Admission is $3.00 per family in advance; $3.50 at the door. Talk-in on 146.13/.73, 146.04/.64, and 222.34/223.94. For information, write PO Box 3088, Vero Beach FL 32960.

FORT WALTON BEACH FL
MAR 22-23

The Playground Amateur Radio Club will hold its 10th anniversary swapfest on Saturday and Sunday, March 22-23, 1980, from 8:00 am to 4:00 pm each day, at the Okaloosa County Shrine Fairgrounds, Fort Walton Beach, Florida.

TIMONIUM MD
MAR 30

The Baltimore Amateur Radio Club will hold its greater Baltimore Hamboree and Computerfest on March 30, 1980, at the Maryland State Fairgrounds, just off I-83, 2 miles North of I-695, Timonium, Maryland. There will be plenty of space for dealers, displays, tables, and commercial exhibits. Special events, lectures, and demonstrations will be held. Food service will be provided. There will be acres of space for tailgate sales. Door prizes will be awarded throughout the day. Admission is $3.00 and tables are $5.00. Talk-in on the BARC repeaters, 146.07/.67 and 146.34/.94. For additional information, tickets, and space reservations, please write to Joseph A. Lochte, Jr., 2136 Pine Valley Drive, Timonium MD 21093, or for a recorded message, dial (301)-HAM-TALK.

ST. CLAIR SHORES MI
APR 13

The South Eastern Michigan Amateur Radio Association will hold its 22nd annual hamfest on April 13, 1980, from 8:00 am to 3:00 pm at South Lake High School, 21900 E. Nine Mile Road (at Mack Ave.), St. Clair Shores, Michigan.

ST. LOUIS MO
MAY 24-25

The ARRL Midwest and Central Divisions will hold their amateur radio and computer hobbyist convention on May 24-25, 1980, at the Cervantes Convention Center, St. Louis, Missouri. Featured will be prominent speakers, information forums, equipment displays and demonstrations, and an indoor flea-market sale. Friday night, May 23rd, will be "Amateur Radio Night" at Busch Memorial Stadium, where the St. Louis Cardinals will play the San Diego Padres. On Saturday night, May 24th, the convention banquet and dance will be held on the riverboat *Admiral*. On Memorial Day, May 26th, there will be an all-day visit to Six Flags Over Mid-America. For more information, write to Gateway Amateur Radio Association, Inc., Box 68, Marissa IL 62257.

Corrections

Several minor errors crept into my article, "Add Digital Display for $50," which appeared in the June, 1979, issue of *73*.

In column two of page 28, 5445 kHz should read 5455 kHz (twice), and 4995 kHz should be 4955 kHz.

The crystal frequency in Fig. 1 should be 5455 kHz.

The "5" or "9" switch position indications in Fig. 3 should read "9" or "4".

The reset line for the 7490 is missing in Fig. 3 and should connect to pins 2 and 3 of the 7490. Pin 3 should not be grounded.

S1 and S2 are push-button switches.

I would suggest using 74LS components in the counter since they should substantially reduce power and heat.

I have had many requests for circuit boards, but unfortunately they are not available at this time. Also, my address has changed since the article was published.

Richard C. Jaeger K4IQJ
727 McKinley Avenue
Auburn AL 36830

J. C. Pinckney WB2VNM has pointed out a mistake in my article ("Experimenter's Corner: The MM5369N") which appeared in the September issue. In the article, I stated that 3.579545 MHz divided through three MM5369Ns gives you 1 Hz every 1.88 years. Joe is correct in pointing out that 1 Hz is one cycle per second and that what you indeed get is one cycle every 1.88 years. I managed to miss that correction during my proofreading and apologize for the error.

Charles B. Patten
Andrews AFB MD

New Products

from page 34

frequencies (±75 Hz). A minor annoyance here is that these two controls do not possess a detent or click-stop to indicate when they are in the neutral position. Both controls are always active and cannot be switched off.

Instead of the usual rf gain pot, the Astro 150 has an i-f gain control. When receiving strong signals, reducing the i-f gain eliminates much of the normal background noise. The proper use of this control can substantially reduce the fatigue that sets in after several hours of listening.

The front-panel meter does double duty as a conventional S-meter and as a power output meter. In the transmit mode, it functions as a peak-reading wattmeter. It is accurately calibrated at the factory.

There are a host of other controls and adjustments which are accessed either through small holes in the transceiver's side panels or by removing the top and bottom covers. There are separate adjustments for VOX and CW delay (when semi-break-in is used), VOX gain, VOX antitrip, sidetone level, S-meter calibration, AGC threshold, and microphone scan rate.

On the Air

Getting the Astro 150 out of the box and on the air is a five-minute job. It's simply a matter of plugging in the power supply, speaker, and mic cables, attaching the antenna of your choice, and flipping on the power supply and transceiver power switches.

When you first apply power, the speaker is quiet for 10-15 seconds, while the PLLs lock on. The frequency display places a decimal point after each digit while this is going on so you'll know what's happening. When the decimal points blink off, the speaker springs to life, and you're set to go.

It took me a couple of days to evolve my own favorite technique for using the 150's tuning controls. A Swan representative told me that others have come to the same conclusions I did. I found the VRS knob best suited for fairly large excursions across a band, say 25 or more kHz. Then, when I was in the vicinity of my desired frequency, I switched to the pushbuttons atop the microphone. At first, this might sound like an unwieldy method of tuning, but it becomes quite natural once you've done it a few times. The push-buttons make it easy to tune up and down from your chosen spot while leaning back in your operating chair—a sort of remote control.

Dozens of contacts on every band produced many good comments about the audio quality of the rig. I ran most of the time without a linear amplifier and had no problem making plenty of DX contacts.

I had never used full break-in before checking out the 150. For most operation, I'll probably stick with the more familiar semi-break-in. When using QSK, one hears what's happening on the frequency between each dit and dah. Thus, it's possible to hear QRM while you are still transmitting and to cut your transmission short, in order to avoid competing with the QRM. Of course, experienced traffic handlers often find QSK a must. When both the sending and receiving stations are so equipped, the receiver can immediately interrupt the sender if he misses a portion of the message. I find QSK operation to be a little bit distracting after years of operating CW in silence. The break-in on the Astro 150 performed flawlessly.

Conclusion

The Astro 150 (and 151) carries a suggested price of $925, making it the least expensive synthesized HF rig I've seen. The PSU-5 Power Supply/Speaker is $179.95. The rig is worlds apart from the majority of transceivers available today, both on the outside and on the inside. Swan has taken a very different approach to transceiver design, starting from square one to produce a radio that takes full advantage of modern digital technology. The only allegiance to the past would seem to be the single conversion receiver, something Swan has long favored.

If you would rather operate than twiddle with a lot of knobs, and you want to go with thoroughly modern technology, the Astro 150 is an awfully attractive value. For further information, contact *Swan Electronics, 305 Airport Road, Oceanside CA 92054; (714)-757-7525.* Reader Service number S44.

THE WILSON SYSTEMS, INC., SYSTEM 33 TRIBANDER

Until now, the antenna farm at my QTH consisted of a monoband yagi for 20 meters on a Rohn BX-32 tower and a Wilson WV-1 vertical roof-mounted on the roof of the garage. Both antennas have performed well for both CW and SSB operation, but with the increase in sunspot activity, it has been my desire to replace the monobander with a good triband yagi beam. Lot size and tower limitations have precluded erection of the larger "DX" tribanders, so it was decided to investigate the three-element variety of beams.

Consulting with other amateurs who own tribanders and comparing the published swr curves of the various manufacturers, I finally opted for the Wilson Systems, Inc., System 33 (formerly System Three). After having purchased a Wilson WV-1 four-band vertical, I have come to accept that Wilson's swr curves were not only the most desirable, but also the most believable. The published curves indicate that the System 33 is a reasonable compromise for the amateur who wishes to work both the CW and phone portions of the 10-, 15-, and 20-meter bands.

Mechanical Construction and Assembly

Like the WV-1 vertical, the System 33 is well constructed mechanically. The boom is 14' 4" long, 2" in diameter, and comes in three sections which fit together and are held in place with heavy-duty zinc-plated muffler clamps. From the consumer's point of view, the three-piece boom is a blessing; it allows for a compact shipping carton which can be reasonably handled by UPS (truck shipments of other beams have cost twice as much to ship for about the same weight class).

When assembling the boom, I would advise that the simple addition of a bolt or heavy sheet-metal screw at the junction of each boom section be made. This should be done in order to keep the boom from twisting in heavy winds, as the muffler clamp U-bolts are not threaded far enough to snug the sections together adequately. The center section of the boom which clamps to the mast is double-wall aluminum tubing and a striking example of Wilson's mechanical overkill. The boom is attached to the mast (not supplied) with a ¼"-thick aluminum plate and 8 heavy muffler clamps.

Unlike other moderately-priced beams, the System 33's elements are heavy-duty, tapering from 1¼" where the elements meet the boom to ⅝" at the ends. The dual-section traps are affixed to the elements at approximately 32 inches from the ends of the elements. Despite their large size, there is very little droop to the elements. Each trap is clearly identified with a sticker which indicates director, driven element, or reflector and has an arrow to indicate the direction toward the boom (little chance for error here). The director and reflector are attached to the boom with a unique one-piece extruded aluminum clamp which fits around the boom. When the clamp is tightened, equal pressure is applied in all directions around the boom so that boom

Assembled weight (approx.)	37 lbs.
Shipping weight (approx.)	42 lbs.
Maximum wind survival	100 mph

Table 2. Manufacturer's specifications.

flattening does not occur. The clamp which holds the split-dipole driven element in place is similar to the clamps used on other popular beams and seems more than adequate mechanically and electrically.

Element sections are joined by one-piece aluminum clamps which provide for good electrical bonding and effective mechanical holding ability because the element sections will dimple slightly when tightened. The dimples will prevent element sections from sliding out of place.

The antenna is fed at the center of the split-dipole driven element with 50-Ohm coaxial cable such as RG-8/U, and there are no matching sections to adjust or stubs to tune. Resonance is set by adjusting the length of the driven and parasitic elements according to the dimensions given in the instruction manual. A balun (1:1 impedance ratio) may be used if one wishes, but it is not necessary.

Electrical Characteristics

A definite advantage of the System 33 over other triband beams is the broadband response of the antenna. It is possible to work almost all of the CW and phone portions of the three bands while maintaining a reasonably low standing-wave ratio. My primary interest is CW and the lower portion of the phone band for DX purposes, so the antenna was adjusted for the CW setting. Table 1 illustrates the swr response for the System 33 at 33' above ground. With regard to swr, the results obtained were better than the data published by the manufacturer. See Table 1.

Although it has not been tried at my QTH, I believe that the response values listed in Table 1 could be improved by shortening the dimension of the adjustable part of each element by about 1 to 2 inches less than the CW setting. Despite the somewhat high swr on ten-meter phone, it appears that the beam is more broadbanded than most of the tribanders I have had the opportunity to own or work with.

Results and General Conclusions

On-the-air results have been gratifying. With regard to forward gain, results indicate that gain is at, or near, the published 8-dB value. The subjective difference between the System 33 and my three-element monobander for 20 meters is minimal. The front-to-side ratio is excellent, with a clear null heard when the antenna is positioned 90 degrees off the desired heading. The only major difference between the System 33 and the monobander is in the area of front-to-back ratio. The front-to-back ratio is at least as good as other triband beams, though.

All things being considered, I can highly recommend the Wilson System 33 for its superior mechanical construction, the ease with which it can be assembled, and its true broadband response. The System 33 is an excellent value and a wise choice. *Wilson Systems, Inc., 4286 S. New Bearcat® 300 Service Search.

NEW BEARCAT® SCANNER HAS OVER 2,000 FREQUENCIES IN MEMORY

The development of a new scanning monitor radio with over 2,000 pre-programmed frequencies, plus 50 user-programmable channels, has been announced by Electra Company. Named the "Bearcat® 300 Service Search," the new radio features the convenience and simplicity of advanced programmed scanner technology. By pushing a single button, the radio will search the actively assigned frequencies for the service selected. This feature completely eliminates the need to know in advance the frequencies for the most-listened-to services. The Service Search has 11 different services: police, fire, marine, "ham," mobile phone, emergency, government, forestry, business, ground transportation, and even air-to-ground aircraft channels. In all, there are 2,138 frequencies pre-programmed into the Service Search memory to ensure that the active channels for any local area are covered.

In addition to Service Search, the new Bearcat scanner also features the flexibility of a user-programmable memory. The frequencies for up to 50 channels can be stored or changed in this memory by simple keyboard entry. These frequencies can be in any mix from the 7 VHF and UHF frequency bands covered by the radio, including the AM aircraft band. Lockout, scan delay, and automatic activation of accessories (such as an alarm) can also be individually entered for each of the 50 channels. Arranged in banks, these channels can be activated or locked out in groups of 10 with a single push-button. Many other operating features are also included in this deluxe radio, including "search" between operator selected frequency limits, hold and resume controls, direct channel access without the need to "step through" channels, scan speed control, plus provisions for a priority override channel.

The clean, professional look of the new Bearcat 300 Service Search scanner features a die-cast front panel which is accented by a vacuum fluorescent digital display. The display, with bright/dim control, offers excellent readability under all lighting conditions. It not only displays the frequency being received, but also automatically shows accurate digital time when the radio is switched off. (If desired, the time can also be viewed when the radio is receiving calls by simply pushing the "time" button.) The radio measures 12¼" wide by 3⅞" high by 7" deep, permitting easy shelf or vehicle installations. Electra Company believes the radio will add a new dimension to the rapidly expanding market for scanner radios, which have already penetrated approximately 5% of US households. The radio is expected to appeal not only to sophisticated scanner users, but also to those who appreciate a unique entertainment product combining complex technology with simplicity of operation. Complete details are available from Bearcat scanner suppliers or by writing directly to *Electra Company, PO Box 29243, Cumberland IN 46229.* Reader Service number E40.

CHECKING OUT THE CLEGG AB-144 ALL-BANDER

I'm a sucker for every new transceiver add-on, accessory, and gadget. My most recent acquisition of this nature is the Clegg AB-144 All-Bander receiving upconverter, which I purchased for use with my two fixed-station 2-meter multimode transceivers.

The AB-144 is a novel frequency-range extending device that should be of interest to amateurs who would like to expand the coverage of their VHF set. The Clegg unit converts your present ham-bands-only transceiver to a continuous-coverage receiver that spans the spectrum from LF (100 kHz) to 30 MHz with no gaps. Because it works ahead of the set's rf and i-f stages, it covers this frequency range with sensitivity, selectivity, tuning rate, calibration accuracy, and mode selection (SSB, AM, CW, etc.) essentially as estab-

Band	Tuning Range
1	0.1-4 MHz
2	3.0-7 MHz
3	7.0-11 MHz
4	11.0-15 MHz
5	14.0-18 MHz
6	18.0-22 MHz
7	22.0-27 MHz
8	26.0-30 MHz

Table 1. Tuning ranges.

lished by your existing rig.

Although the unit was not yet available when the first ads appeared in early spring, it took Clegg less than one week to get the AB-144 to me by UPS when I placed my order this summer. Upon unpacking the 2-lb. unit (which came in a securely wrapped and padded box), a quick scan of the 3-page operating manual provided all the instruction needed to connect the upconverter to my Yaesu FT-221R transceiver.

A 110-volt, 100-mA, plug-in, ac-adapter-type power supply is furnished, and it's more than adequate to supply the 12 V dc @ 30 mA required by the AB-144, though you can also tap into the transceiver's dc supply if you like. I found that two additional connections, in addition to the power supply cable, had to be made. The first was the output line to the transceiver, which was made by means of a short length of RG-58 cable terminated in PL-259 connectors (user-supplied). A jack is also provided on the rear panel to connect a suitable LF/HF antenna. (A single wire will normally do fine, or if your transceiver has a separate antenna/receiver jack, you may be able to use it as a handy spot to feed in the upconverter's output.)

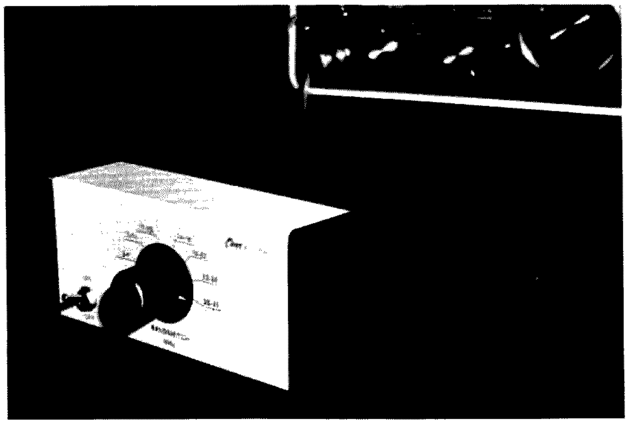
Hooking up the two rf cables and the power cord put the AB-144 in operation. There was one final step, however. I took the precaution of removing the microphone from the transceiver to prevent the accidental pumping of 2-meter rf into the AB-144—an easy thing to do if you later forget that the unit is connected. Although the upconverter is internally protected against such an unfortunate occurrence, this added measure will prevent possible damage to either piece of equipment.

I found that the Clegg unit did what the advertising literature claimed it would do. It nicely extended the range of my FT-221R down to 100 kHz, making the purchase of a high-quality all-band communications receiver of marginal value, especially considering the relatively low cost of the Clegg upconverter ($129.95) and the high cost of top-quality receivers in today's market.

Specifically, the specs call for 0.3 microvolt sensitivity (on SSB and CW) and a ±3 kHz (±1 kHz typical) frequency calibration accuracy. Selectivity is equal to that of the transceiver with which it is used. While I did not measure the sensitivity, it seemed to be at least equal to my Tempo 2020 on the ham bands and my Yaesu FRG-7 over the full range of 100 kHz to 30 MHz. Calibration accuracy was found to be close to the ±1 kHz figure. Frequency stability was excellent; no trace of drift or instability was noticed with movement of the cabinet.

Overall results you can expect to obtain with the AB-144 depend almost completely on the transceiver you feed with the upconverter's output. When using the unit with my FT-221R, which is also equipped with an outboard YC-221 digital readout display, it was a real convenience to have both analog and digital frequency display on all bands, especially the crowded AM broadcast and shortwave bands. FM and SSB reception was excellent, mainly because the Yaesu transceiver is primarily designed for these modes. CW reception was broad, as expected, due to the transceiver's i-f passband characteristics, though addition of a sharp active audio filter (such as those sold by MFJ, Autek Research, Datong, and others) would easily narrow the effective passband for better CW reception. AM reception results were marginal because the FT-221R's i-f filters are designed for SSB, having a too narrow 2.4-kHz bandwidth. The narrow AM selectivity results in some distortion, bassiness, and low audio recovery on received signals. While AM reception was usable on my transceiver, this problem might prove detrimental to avid broadcast-band and shortwave listeners. Again, this is not a problem of the converter, but of the transceiver with which it is used. If you intend to use the AB-144 with your present VHF gear, you may want to modify the set's i-f passband to broaden its AM response curve.

It also took a little "getting used to" and some rapid mental gymnastics to calculate how each of the eight band segments are upconverted to 144-148 MHz. Each band is 4 MHz wide (corresponding to the width of the 2-meter band), except the first band, which is only 3.9 MHz wide—remember, the set only goes down to 100 kHz, not 0 kHz. The bottom of each of the upconverter's eight bands is heterodyned up to 144 MHz by means of eight separate crystal oscillator circuits; the conversion process is worked upwards from there. For example, to receive a BC-band station at 1060 kHz, set the bandswitch on the AB-144 to band 1 (.1-4 MHz) and tune the transceiver



Clegg's AB-144 All-Bander.

to 145.060 MHz. Or, to receive a 3900-MHz signal, set the switch to band 2 (3-7 MHz) and dial in 144.900 MHz on the transceiver. This process *can* be confusing, with either analog or digital displays (especially the latter) until you get the hang of it. The complete tuning ranges are shown in Table 1.

I also tried out the AB-144 with my KLM 2700 transceiver, which has both a vfo (with an analog display) and a digital readout controlled by a 3-knob digital synthesizer. I found the analog display easy to work with on this set, especially since the 2-meter band was split into four 1-MHz ranges which coincided nicely with the upconverter. But the digital synthesizer—with its 3-knob tuning divided into 1-MHz, 100-kHz, and 10-kHz frequency increments and its resultant inability to directly dial in frequencies other than in 10-kHz steps—was just "too much" to get used to. However, the synthesizer was great for BC-band DXing, where most channel separations in North and South America are pegged at 10 kHz; you can set up the synthesizer and whip through the band at exact 10-kHz intervals with ease.

SSB and CW reception was good on the KLM 2700, about the same as on the FT-221R, and AM was a little better on this rig. (Some transceiver manufacturers recognize the AM reception problem and make available information on how to improve reception. KLM, for example, has issued a technical bulletin on the 2700 which shows how to broaden the AM-mode response curve for improved AM signal quality. The modification they suggest for the 2700 involves only two components, a resistor and a capacitor. I installed the modification on my set and found reception quite acceptable on the standard and shortwave broadcast bands.) Clegg mentions that the AB-144 is designed for use with the FT-225, TS-700, and IC-211, in addition to the two transceivers with which I used my unit.

What was inside the attractive 5¼" × 2½" × 6" Ten-Tec-style enclosure? The instruction manual didn't provide a clue, and no schematic diagram or servicing procedures were included (Clegg warrants the unit for 1 year and expects that you'll send the device back to them for repair). I was disappointed in not having been provided a diagram, so I peeked inside and found a small rectangular circuit board holding a 10-transistor circuit, with separate oscillators for each of the eight bands. Although it's not necessary to perform any internal adjustments or alignment unless components have been replaced and repairs made, I managed to touch up each oscillator's tuning slug to bring the frequency calibration accuracy under 1 kHz on all bands and to slightly peak up the unit's output. In examining the AB-144, I found workmanship to be good throughout.

Is it worth it? Yes, especially when compared with the alternatives of buying a separate general-coverage receiver or another of the recently-introduced upconverters designed to capture this wide-open market. I was impressed by the Clegg unit's very few birdies and images, its good calibration accuracy and resettability, and its reasonably consistent performance over each band and from band to band. You *do* have to be careful with overload, however. Cross-modulation is not as much of a problem (though there was a trace on some close-by BC stations), but overloading the transceiver on strong signals was. This is because there is no tie-in with the transceiver's agc circuit. This means that you do have to do some manual rf gain control riding, espcially on SSB and AM, for best results. Also, I

found that the external ac adapter power supply furnished with the AB-144 produced a small amount of hum on stronger signals; hooking into the transceiver's dc supply cured the problem. Too, I would recommend that Clegg add a small LED indicator to let you know that the unit is on; unless you're hooked into your set's power supply, it's easy to forget to turn off the upconverter when you turn off your rig.

Finally, you need to be careful not to zap the converter with a healthy dose of rf from your set, as I've indicated. Installing a coax switch at your transceiver's output connector will allow you to conveniently switch from converter to normal transceiver operation. A coax relay could also be used, but that would require going inside the AB-144 to arrange switching.

All in all, the Clegg people have produced a handy, useful accessory to be used with the thousands of all-mode VHF transceivers in operation today. I should also mention that Clegg has now introduced a similar upconverter, known as the MD-28-9, which transforms your ham-bands-only HF transceiver or receiver to a wide-range 100-kHz-to-18-MHz unit. With this unit, the received signals are heterodyned to the 10-meter band rather than to 2 meters.

In my opinion, the AB-144 is a real jewel that is well worth its price tag. It's an especially attractive purchase for the ham newcomer who entered the hobby from CB radio and who invested first in a 2-meter rig, rather than a shortwave set. Besides providing a good auxiliary receiver for my shack, the Clegg unit will be a welcome addition on my vacation trips to enable me to monitor HF with the 2-meter rig. *Clegg Communications Corp., 1911 Old Homestead Lane, Greenfield Industrial Park East, Lancaster PA 17601; (717)-299-7221.* Reader Service number C3.

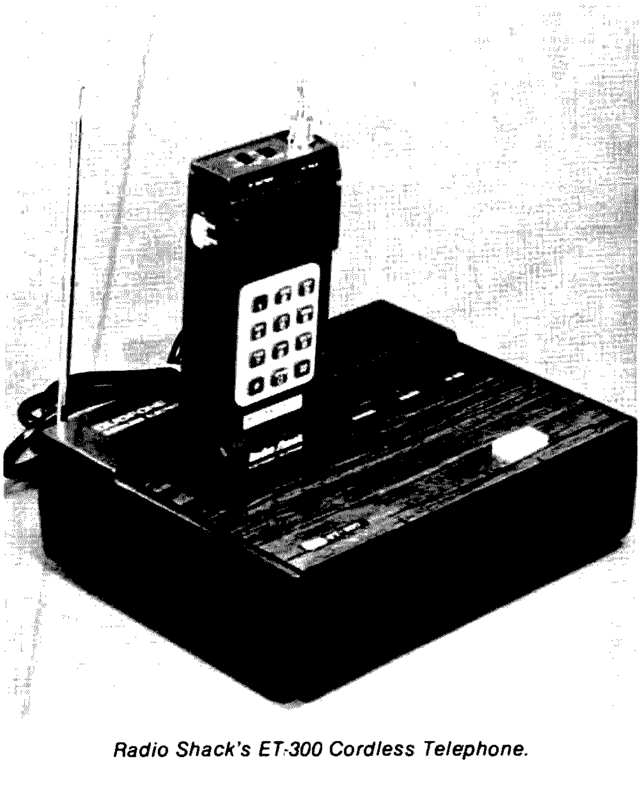
RADIO SHACK CORDLESS TELEPHONE

Now available from Radio Shack is the DuoFone ET-300 Cordless Push-button Telephone with an operating range of up to 300 feet from the base unit. It has a universal dial system for compatibility with both electronic push-button and mechanical dial telephone systems.

The ET-300 can be installed simply by plugging the base/recharger into a 120 V ac outlet and a modular phone jack—no other wiring is required.

A special feature of the phone is Auto-Redial, for one-button redialing of the last number called if it was busy or did not answer. A call push-button lets you signal the handset from the base with a tone signal.

To answer or make a call on the cordless handset, flip the talk switch and raise the antenna. To hang up, lower the antenna.



Radio Shack's ET-300 Cordless Telephone.

Trac's TE284 Deluxe Message Memory Keyer.

The base/recharger is 8⅝" x 7⅛" x 2¾" and includes a built-in modular jack for your regular phone. The handset is 2½" x 6¾" x 1¼".

For further information, contact *Radio Shack, 1300 One Tandy Center, Fort Worth TX 76102.*

TRAC DELUXE MESSAGE MEMORY KEYER

Trac Electronics, Inc., has introduced a new, completely CMOS, state-of-the-art, Deluxe Message Memory Keyer, the Model TE284. Containing all CMOS integrated circuitry, the Deluxe Message Memory Keyer contains three choices of message storage: two-message capacity (50 characters each), four-message capacity (25 characters each), or one 50-character message and two 25-character messages. The keyer can record at any speed and the message can be replayed at any speed. A memory operating LED tells when the keyer is in the memory function. The three choices of memory operation make the Model TE284 ideal for both daily QSOs and contests. In addition to the message functions, the keyer contains both dot and dash memory keying, iambic keying, 5-50 wpm, speed, volume, tune, tone, and weight controls, as well as a sidetone with speaker. The Model TE284 keys both negative- and positive-keyed rigs. *Trac Electronics, Inc., 1106 Rand Building, Buffalo NY 14203.* Reader Service number T18.

ICM INTRODUCES NEW GROUND STATION SATELLITE RECEIVER

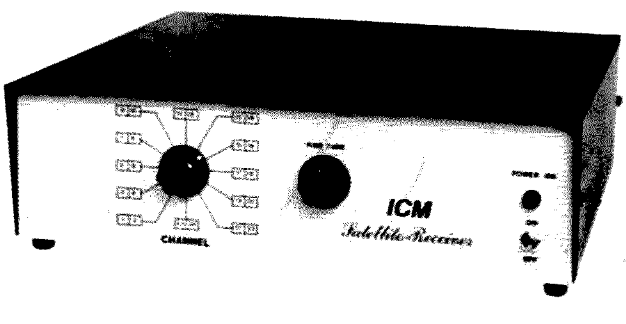
A new low-cost satellite receiver, covering all channels 3.7-4 GHz, is now being manufactured by International Crystal Mfg. Co., Inc., Oklahoma City.

The TV 4200 receiver is fully tunable and provides standard dual audio outputs of 6.2 and 6.8 MHz, with other outputs available. The receiver has a built-in LNA power supply, and output levels are compatible with video-monitor or VTR input.

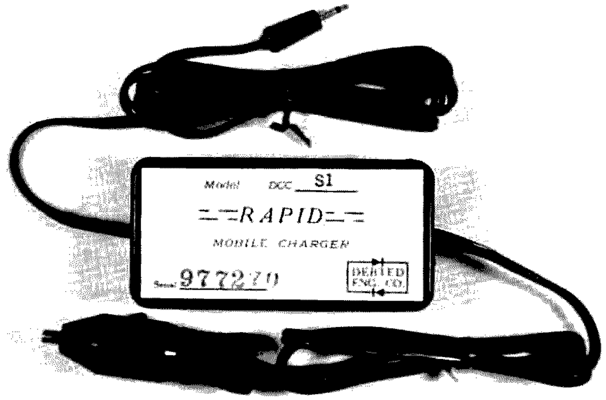
For further information, contact *International Crystal Mfg. Co., Inc., 10 North Lee, Oklahoma City OK 73102.* Reader Service number I48.

RAPID MOBILE CHARGER

With the current trend toward using hand-held transceivers for mobile operation, keeping the hand-held batteries charged has become a problem. DebTed Engineering has solved this problem with a new line of 12-volt-operated rapid chargers for amateur and commercial use. Available exclusively through Debco Electronics, the rapid charger units are equipped with a cigarette lighter plug on the in-



ICM's satellite receiver.



Debco's Rapid Mobile Charger.

The EK-480M keyer from Curtis Electro Devices.

put side and an appropriate charging plug on the output side. Models are currently available for the Tempo S-1, Wilson Mark II, and Wilson Mark IV. The charger will rapidly charge a fully discharged good battery in 4-6 hours and may be used during transmit, receive, and off periods. Furthermore, it will not damage batteries if left connected for prolonged periods of time, due to automatic shut-off circuitry. *Debco Electronics, PO Box 9169, Cincinnati OH 45209.* Reader Service number D68.

HAMTRONICS' UHF FM EXCITER KIT

Continuing in their tradition of making professional quality transmitter and receiver modules, Hamtronics, Inc., has announced a new UHF FM Exciter Kit. The model T450 is rated at 1 Watt for continuous duty, which makes it an ideal unit for repeater and control link service.

Features include low-impedance dynamic mic and receiver audio inputs; crisp, clear modulation; low spurious output; and built-in test points for easy alignment. The unit is designed on a 3" x 5¼" PC board and uses both individual coil shields and compartmental shielding. Double-tuned circuits are used for low spurious output, and decoupling uses ferrite beads and resonant bypasses for stability.

For further information, contact *Hamtronics, Inc., 65F Moul Rd., Hilton NY 14468; (716)-392-9430.* Reader Service number H16.

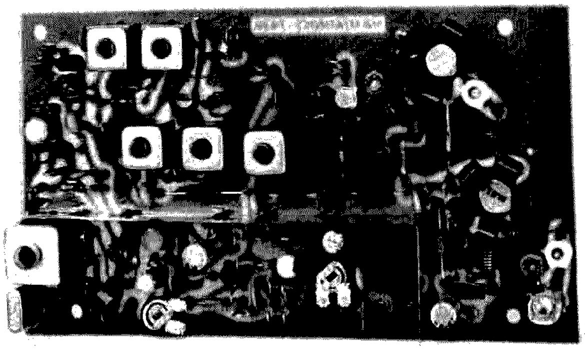
NEW KEYER USES OPTOISOLATORS

An advanced-design electronic keyer employing optoisolators for key isolation has been introduced by Curtis Electro Devices, Inc. Based on the popular 8044 single-chip circuit, the EK-480M features a direct meter readout of code speed in wpm. Measuring only 7" x 4½" x 2½", the unit features dot and dash memories, iambic or standard mode operation, internal 117 V ac or battery supply, internal sidetone and speaker, front-panel volume, pitch, weight, and speed controls, and an accessory socket for soon-to-be-announced message memory, Instructo-Keyer, and keyboard keyer add-on units. The unit will key ± 300 V dc at up to 200 mA.

For additional information, contact *Curtis Electro Devices, Inc., Box 4090, Mountain View CA 94040; (415)-494-7223.* Reader Service number C90.

THE ISOPOLE™ CONT.

We should have noted in our October issue (p. 167) that AEA's new ISOPOLE™ is indeed a VHF antenna. Versions are available for 2m and 220 MHz.



Hamtronics' UHF FM Exciter.

Ham Help

I have recently come into possession of an Elmac receiver, Model PMR-6A. I have not been able to find any info on this unit. I do not have the power supply, but I understand that it was a mobile unit.

I need a schematic for the unit and a list of the voltages needed for operation so a power supply can be assembled. I will appreciate any help and will happily reimburse copying and postage costs involved. Thank you.

DX

from page 30

quency, that is, on the frequency of his last station worked. Either a remote vfo on your transceiver, RIT (receiver incremental tuning), or a separate transmitter and receiver is required. Any of these setups will accomplish the goal.

First, tune in the DX operator and listen while he works one or two stations, to establish in your mind what his operating pattern is. Books and articles have preached this simple rule for decades. When your radios are warmed up and tuned up (off the air, naturally), get ready to put your transmitter on the proper spot. When the DX turns it over to someone, find that someone and put your signal just slightly off his frequency—off a matter of Hertz, *not* kilohertz!

That's all there is to it. When you call, your signal should be right where the DX station's receiver is tuned, and he will hear you without touching his receiver tuning knob. If the DX operator is getting calls by carefully listening for "tail-enders," you have no choice but to play his game and tail-end yourself. Tail-ending means giving your call, or just your suffix, at the very end of the transmission of the station who is signing off with the DX. A very skilled operator can pick out parts of callsigns from tail-enders and can keep a string going without ever saying "QRZ?" or whatever. Mostly, however, tail-ending degenerates into a mob scene. *Never* use the technique unless the DX station encourages it, and even then only if it is working.

It's difficult to not feel smug after finding a pileup, observing the poor slobs who call and call but never figure out what is happening, then make one or two quick calls yourself, exchange reports, and tune away looking for more rare QSOs, while the same pileup goes on and on. There's something more training classes should teach: It's called using your head. Put yourself in the shoes of the DX station you want to work. Think like he does and you will invariably call at the right time on the right frequency. Otherwise, you can call all night.

160 METERS

December is the time to talk about our lowest frequency band, since the winter months are to 160 as the summer months are to sporadic "E" skip on VHF. Many modern rigs cover 1.8 MHz, and the amateur magazines have had their share of tips the last couple of years on how to put a signal on 160 when only modest real estate is available. A dipole is 270 feet long, a fact which constrains most of us. But there are ways!

Many have become interested in 160 since the hundred-country barrier was broken a couple of years ago. As we recall, W1BB actually had the magic century figure some time before, but a few of the countries were "pre-War" and didn't count when the ARRL decided to offer a 160 endorsement to DXCC. By 1979, several have made this achievement level. Now most expeditions to rare spots include 160-meter coverage, as well as 6 meters and OSCAR. When one has worked his fill of Europeans or JA stations on 80, 160 becomes the natural band to which to gravitate for more thrills.

DX on 160 is found primarily in the "window," 1825-1830. *Do not* transmit in this segment unless you are outside of the US and Canada. The DX will specify a listening frequency around the bottom edge of the band, 1800-1805. Pacific island stations such as Hawaii will transmit near the top edge of the band, as will JA stations. Send an SASE to the ARRL and ask for their special chart of 160-meter allocations, which includes information on how much power you can use at various times of day and night in different regions of the US.

Six-Band DXCC, anyone? (It's been done!)

MAILBAG

KV4FZ reminds us that he was the first operator outside the 50 states to make WAS on 160 meters; PY1RO, mentioned in this column last July, was the first station outside North America to accomplish the feat. Herb KV4FZ has also confirmed 100 countries on six different bands, 160-10 meters.

A nice letter came from Cliff Sides KX6SC, who, along with Ed Williams KX6SA, has been keeping the Kwajalein Atoll active. They have been on 6 meters, with consistent openings to Japan, Hawaii (2000 miles NE of KX6), Guam, the Solomon Islands, Papua-New Guinea, and Jordan. Some openings to Australia and New Zealand have also occurred.

Their best time on 50 MHz, where they hang out around 50.110, has been 0900 to 1200 UTC. If you can hear KH6 stations this winter, you may work a real rare one if the skip runs to KX6.

Here's how Cliff summarizes the low-band openings:

10 Meters: Open from Kwajalein sunrise to sunset (1800-0600 UTC); Europe comes in first, followed by stateside and VK, then Japan at night between 0600 and sunrise.

15 Meters: Open sunup to sundown, very similar to 10.

20 Meters: Best openings to the US occur between 0300 and 0800 and again between 1100 and 1500. Europe is very good between 0500 and 2200.

80 Meters: Propagation to the US peaks about 1400, Europe slightly later. East-coast US stations have the best shot at this part of the world at their sunrise on the east coast, about 1200 UTC in the winter.

The first expedition to VK9 (Cocos-Keeling) in some time took place September 18 and 19, 1979. VQ9s JJ, KK, and MR (yes, the same one mentioned in Novice Corner) started out by having their plane delayed 24 hours. They finally arrived on Cocos Island (about 1500 miles from their homes on Diego Garcia) and fired up at 0830 UTC on the 18th.

Their next problem was dead bands. Our active sun, responsible for the excellent propagation on the bands these days, greeted the Cocos group with the residual effects of a solar flare. The bands came back to life a little toward the end of their two-day stay, but working them from stateside, for example, was no picnic.

In 30 hours, the trio did manage some 2200 contacts, almost all on 15 and 20 meters. For those who missed this one, there's good news: VQ9JJ and VQ9TR are talking about going back early in 1980, with a beam antenna this time.

August, 1979, was a banner month for expeditions. Manihiki (Northern Cooks chain) Island was represented by no less than two different groups. KØSVW provided a report on one, which signed ZK1AM. Other operators were WØWP, KØEVE, and ZK1DR; they made 15,000 contacts on 80-10 meters. WØWP is handling QSLs, which were supplied by Collins Radio.

ZK1AM was on the air August 18-25, using a pair of IC-701s, an FTDX-400, and loaned TH3 Hy-Gain beams and DenTron amplifiers. Expenses for the operation, including a six-day boat ride each way, totaled twelve thousand dollars, which was paid by the participants. If your group is interested in seeing the slide show and talk on this interesting adventure, contact Dr. Steve Towle KØSVW, 214 N. 34th Avenue East, Duluth MN 55804.

September's Hurricane David devastated the island of Dominica in the Caribbean. David wiped out all communications there except for amateur radio. J7DAY was all alone for the first few days and provided all government-to-government communications for relief operations.

J7DAY was joined by KP2A (American Virgin Islands) and WØDX. They set up at a Red Cross headquarters first as KP2A/J7 and then as J73A. W4UY joined them later. As things got in order, J73A was able to do some casual operating; if you worked them and would like the special QSL card, send yours with an SASE to K2TJ.

As you read this, the Indian Ocean-Africa expedition by N2KK, K5CO, and N5AU should be in full swing. Their itinerary includes 3B7 and 3B9, Glorioso and Juan de Nova, and then Mayotte and 5R8 (Malagasy Republic). After that, N2KK hopes to get into Somalia (6O) solo.

Dave N2KK is a professional photographer who has traveled extensively throughout the world (to more than 100 countries). He will be taking many photos during the expedition and will undoubtedly be prepared for the "convention circuit" upon his return.

If you worked KP4AM/D (Desecheo) last spring, you might want to send your QSL now to David Novoa KP4AM, PO Box 50073, Levittown PR 00950.

VE3FXT should be operating from Thailand by now, after getting in some air time from HS4AMA while awaiting his own callsign. Also active from there, of course, is Fred Laun HS1ABD. Fred listens for stateside and Canada on 3517 at 1130 daily.

The December issue of *CQ* magazine, a publication which has been quite DX-oriented over the years, is the first under the new management of K2MGA, K2EEK, and W2LZX. Among other things, CQ has sponsored the Worldwide DX Contest, the WPX (prefix) contest, and a 160-meter contest, not to mention an awards program, including the USA-CA (US counties) award. It is expected that *CQ's* emphasis will continue mostly unchanged, at least for the time being.

With the departure of Chuck Stuart N5KC as editor of this column, new authorship begins with this issue of *73*. Please send your input c/o *73*, Peterborough NH 03458. And thanks from all DXers to Chuck Stuart for the excellent work he has done with the column during the past year!

Most of the information for this column came from *The DX Bulletin* (Vernon CT 06066). Thanks.

Looking West

from page 18

and other "radio tricks" and increased lawlessness.

Where Are We Headed?

As this lawless group becomes larger and more powerful, it will become more fearless. It will also become more sophisticated in the "art" of raising hell via radio technology.

Please realize that the driving force of this group is an ego trip based on the power they can apply to other parts of society. Also, be aware that this sort of ego trip *can never be satisfied.* That is to say, once they have their way with the ham bands, they will begin to turn their eyes (egos) to other targets.

What targets might these be? What with scanners in abundance, targets are very easy to find. What about mobile radio services, taxis, fire, police, etc.? I can imagine thinking like the following:

"Wouldn't it be a lot of fun to study the fire frequencies and learn how to get around their security systems and send half of the LA Fire Department out on a wild-goose chase? Wow! That was fun. Next week, let's fake LAPD into another Watts riot!" Or, "Let's talk to a 747 pilot coming into LAX and burn his ears!"

The technology is not too difficult for this group of lawless people. They already know how to put a synthesized 2m transceiver well outside its design band limits. They know the frequencies that many services and individual agencies use. They know a great deal more.

I don't wish to be disrespectful of the FCC and its abilities, but I feel it would take quite a while to nail someone who is doing the things I project above. Meanwhile, the FCC receives a tremendous black eye, and society will pay a large bill in monies, property, and maybe lives.

What To Do?

It seems to me there are several choices:

1. Do nothing. Result:
•Eventual anarchy within the whole radio spectrum.
•FCC in total disgrace.

2. Vigilante action. Result:
•People hospitalized.
•Houses burned.
•Innocent parties hurt.
•"Good" people (vigilantes) sued and hurt.
•FCC gets black eye.

3. FCC participation in restoring law and order to the ham bands. Result:
•Stop anarchy before it spreads further into the non-ham parts of the spectrum (where the FCC would not have a vast army of hams to help with the clean-up).
•Cooperation from those of us hams who have developed RDF skills and equipment. This will aid the FCC in its work.
•Restoration of what is probably the most effective weapon of all—peer pressure in the form of fear of exposure to the FCC.
•FCC gains respect and stature.

* * * * *

The only question left is: "When will the tide begin to change back in the direction of collective decency?" Maybe the shift has already begun.

BYE-BYE, MISS AMERICAN PIE DEPARTMENT

On September 6th, the FCC acted to suspend, pending revocation action, both the operator's and station license of Scott Lookholder WB6LHB of Los Angeles, California. Earlier this year, Lookholder had entered a guilty plea in federal court on a number of counts in an indictment charging him with the use of "foul and abusive language" while operating on the two-meter amateur band. Allegedly using the callsign W6JAM, Lookholder spent many hours making life miserable for the usership of many Los Angeles area repeaters, especially the Mt. Lee WR6ABN repeater.

Ironically, Lookholder was even a member of the DFing committee set up to catch W6JAM, and it was only due to some rather phenomenal detective work by another member of that same committee that he was caught at all. Even after they were sure that Lookholder was their man, they found it hard to believe and spent many hours trying to disprove their "find" before turning their evidence over to the authorities.

The rest you already know. Scott Lookholder was given his day in court, admitted to the charges against him, was sentenced to pay a fine, and was placed on probation. He was also ordered by the judge not to utilize his amateur equipment during the term of the probation. However, though a number of letters were sent to the Commission by area amateurs requesting that Lookholder's license be pulled, the FCC took months to act on the matter. Infuriated, many amateurs charged the FCC with running

Congressman James Corman (left) with Attorney Joe Merdler N6AHU. Both care a lot.

scared of anything that even remotely smelled of First Amendment. Letters to the Commission have gone unanswered, including my own.

In the meantime, the inaction by the Commission on this and other regulatory violations issues helped worsen an already highly volatile situation. The kooks have realized that the FCC is seemingly powerless in this type of matter and have made a field day of it. Filth, racial slurs, character assassination, and hate have replaced normal day-to-day operation on many repeaters. It's even been reported, though not confirmed, that at least one "jamming" club has been formed to further wreak havoc. Carrying their banner of "our way or no way," the kooks have been growing in number and strength. No longer would they hide behind the anonymity of their microphones. Rather, they were proud of who they were and what they were doing. They declared open war on Joe Ham, and Joe was hard put to fight back.

Not every Joe was inclined to sit still and accept the decaying situation, nor every "Jay" for that matter. In what might be considered one of the finest political moves ever initiated within the ARRL, League Southwestern Division Director Jay Holladay W6EJJ convinced the Board of Directors that a *bad* situation did exist and was able to get the Board to pass a resolution which instructed ARRL General Counsel Bob Booth to contact and develop a working guideline with the FCC in handling this type of problem. Jay's next step was to appoint Los Angeles Attorney Joseph Merdler N6AHU as a Special Assistant Director, charged with advising Jay in methods to eliminate this ever-growing maliciousness that was, by this time, threatening to destroy normal amateur operation.

Through Joe, a meeting was arranged with US Congressman James Corman, Democrat from Van Nuys, California, which Jay and Joe attended. Congressman Corman was briefed on the deteriorating situation, the problems with FCC inaction on these cases, and given a basic education about the amateur service itself. As a result of this meeting in August, Congressman Corman agreed to support the amateur community in its internal house-cleaning effort and said that he would see what could be done through Washington. About two weeks later, I personally interviewed Congressman Corman, and what follows is the text of that interview.

Q: Congressman Corman, what led to your decision to get involved in this matter?

A: All of us who have had little contact with amateur radio are still aware of its importance. I'm occasionally aware due to news items of amateurs who have performed important services during times of disaster, maybe an individual disaster or something that affects a whole community. I was not, until recently, aware that there were some problems. Those problems involve the use of false call letters, interference with the normal use of the airwaves, and some serious cases of obscenity. I have discovered that the FCC appears to be doing little to police the use of the airwaves for amateurs and is potentially diminishing this service which the amateur operator can give to his community.

Q: Congressman, now that you are involved, what direction do you intend to take?

A: Joe Merdler (N6AHU), who is a good, long-time friend of mine

and the new president of the Personal Communications Foundation, has given me tapes to show me what is happening on the airwaves, and I'm going to be sure that the FCC hears those tapes. I hope that will generate some action from them. Also, I'm going to be working with Congressman Van Deerlin, who heads the Communications Subcommittee, which has jurisdiction in this area, to see whether or not we need some statutory change, to make certain that the FCC is doing a responsible job of policing the airwaves.

Q: Do you feel that the FCC is doing its job in this matter?

A: Evidence I have at the moment would indicate that they are not! For instance, a man was convicted in a court of law of using both false call letters and obscenities, very serious ones interfering with the normal legal use of the airwaves, and yet the FCC was reluctant to take action against him. He may be punished in a civil court or criminal court, but as long as he has the *ability* to continue to interfere with the normal legal use of the airwaves, then the FCC is not doing its job and I want to find out why.

Q: I assume you are speaking of the Scott Lookholder matter?

A: Yes.

Q: Do you feel that the Commission may be running scared of First Amendment issues in this matter?

A: I'm sure that the FCC feels controlled by the First Amendment, but there are things here that go well beyond First Amendment rights, having to do primarily with interference with other people's use of the airwaves, and clearly there are obscenities that go far beyond one's constitutional right. I know Chairman Ferris and plan to contact him and ask if that's what they're (the FCC) worried about; I want to sort it out and get some legal opinions as to whether or not they can move. It may be that it's something else, and I suspect that something else may very well be that they just get bogged down in the normal bureaucracy and that nobody has paid close attention yet. Maybe I'm wrong and it is something else, but we will find out what it is and try to get to the bottom of it.

Q: Are you going to bring the Lookholder matter to their attention and try to get action on it?

A: Yes. I want to be sure that it is before the chairman of the Commission. He may have a valid reason for not proceeding. I want to know what that reason is. If it is a valid reason, I will come back and report it to the people involved. If it's not a valid reason, I'll try to see that action is taken.

Q: What if some of these alleged "bad guys" charge you with violation of their First Amendment rights? Will you still stand behind the amateur community in its housecleaning efforts?

A: The point is that the courts will protect the First Amendment. There is no First Amendment right to falsifying call letters. There's no First Amendment right to blasting obscenities on the airwaves. Admittedly, obscenity is a difficult thing to determine under the First Amendment, but aside from that, assuming that they are saying something very proper, if they're falsifying call letters and if they are intentionally interfering with the normal use of the airwaves, then it's my suggestion that it is *not* their First Amendment right. I believe very strongly in freedom of speech. Clearly, when you think about the airwaves and their importance, there is the necessity for using them in some reasonable and rational way for all. To use them irrationally, to intentionally jam them, has nothing to do with First Amendment rights in my book.

Q: I understand that you are going to be coordinating your efforts with the American Radio Relay League through its General Counsel, Bob Booth. Would you care to elaborate?

A: I asked if I could see Mr. Booth as soon as I get back to Washington. I'm hoping that Mr. Merdler will be able to come back as well. For one thing, there are 435 of us in the House of Representatives and we don't want to be running in 435 different directions. That's why it's so important that the association (ARRL) quarterback what's going on, so that we are all moving in the same direction. We need to coordinate a good reference.

• • • • •

Less than two weeks after my interview with Congressman James Corman, word reached us that the FCC had acted on the Lookholder case, and since that time, the FCC has apparently been quite busy helping us clean house, not just on two meters, either. Could it be that an overall cleanup of the amateur bands has become an FCC priority? The rumors of almost daily "busts" run rampant, but the FCC refuses to say anything. Following up on such a rumor just this week, Westlink Correspondent Alan Kaul W6RCL called FCC Field Engineer in Charge Larry Guy at the Long Beach field office. How far did he get? Read his final "air copy" here:

NEWS ITEM: THE WESTLINK AMATEUR RADIO NEWS EDITION #106

"In Los Angeles last week, another FCC raid was made on an amateur station allegedly involved in illegal transmissions. Officials from the Long Beach field office took part in the action. In a capsule, here's what happened: A signal from an amateur transmitter was jamming a two-meter repeater in the Los Angeles area. Direction-finding equipment led to the location, but no one was home. Westlink has learned that the jamming operation was done by remote control, and that the owner of the station was activating the transmitter by telephone.

"The FCC refuses to confirm or deny the report, and will say only in terse governmentese: 'An inspection was made on Monday, September 10th, but the results of that inspection are not public information.'

"So, we don't really know what happened and can't really be sure who the ham involved was, but it looks like the score from Los Angeles is FCC 2, jammers nothing."

If there is real validity to the rumors, and I have good reason to believe that such is the case, then it looks as if a cleanup of our amateur bands is our Christmas present to ourselves, with a bit of help from the FCC. The only ones who won't appreciate the gift are the foul-mouthed, the carrier-throwers, and jammers in general. Why? Because the gift they get will probably be notification that they are no longer licensed amateurs; *good riddance*. You see, the "good guys" who wear white hats and ride white horses can win a fight —even today!

Happy holidays!

Microcomputer Interfacing

from page 28

shown in Fig. 1 pressed, a negative pulse of duration 2.62 seconds will also be observed. If you fail to press the pulser, however, and thus do not apply a positive edge at GATE0, no monostable pulse is observed. On the other hand, if you repeatedly press and release the GATE0 pulse at time intervals less than 2.62 seconds, the monostable pulse can be prolonged indefinitely. In this way, a *retriggerable monostable multivibrator* output can be produced.

With a control word of 064, the behavior depicted for MODE 2 in Fig. 2 can be observed. By repeatedly generating positive edges at GATE0 at time intervals of less than 2.62 seconds, counter #0 is repeatedly reset and the appearance of the short negative clock pulses is prevented. The same purpose may be accomplished by allowing GATE0 to remain at logic 0 after a positive edge has been applied. The GATE0 input thus exhibits both gating and trigger/reset behavior.

MODE 3 behavior (control word of 066) is similar to that for MODE 2, except that a nearly symmetrical square wave is produced. Deviations from symmetry occur when the counter byte is an odd number and are most pronounced when the counter byte is very small.

In MODE 4 (control word of 070), the positive edge of the WR pulse (which is applied at pin 23 of the timer when the STA instruction at 003 014 is executed) initiates counting that culminates in the production of a negative clock pulse of pulsewidth T. The time duration between the positive edge and the pulse is 2.62 seconds. The GATE0 input acts as a gating input, with a logic 0 inhibiting the counting process.

Finally, in MODE 5 (control word of 072), a positive edge at GATE0 initiates counting. By repeatedly generating positive edges at GATE0 at time intervals of less than 2.62 seconds, counter #0 is repeatedly reset and the appearance of the single negative clock pulse is presented.

It should be noted that in all modes, counter action begins on the first negative clock transition after WR (pin 23) or GATE0 goes to logic 1, and that WR can initiate counting in all modes except MODE 1 and MODE 5.

Although in many applications of the 8253 timer the primary interest will be to generate the proper signal at OUT0, as shown in Fig. 2, you can also read the contents of the 16-bit counter *without affecting the counting operation*. By inputting a control word of 000, 100, or 200, you latch the 16-bit count of either counter #0, counter #1, or counter #2, respectively. As shown in the memory-mapped I/O example in Table 1, the two bytes can then be read into the 8080A chip, with the LO byte first and the HI byte second.

LETTERS

from page 16

sultant squeal from various troopers to your magazine. I noticed some of the biggest squeals around here came from police who have linears in their patrol cars on CB and they own amateur gear for a home CB station. One local community police department is almost entirely involved in overpower on CB. In fact, in this particular area, a county of maybe 7,000, there are 15 to 18 Yaesus and 7 Siltronix, and linears in autos and home are almost commonplace. Only one Yaesu is owned by a licensed amateur.

Then we see an article printed by a completely illegal, overpowered, out-of-band HFer (Peters) trying to convince us he is just a good ol' guy trying to do his thing, fellas, so please give us HFers some consideration and kindness as they operate like hams and are really good guys. Horse cocky! He is an illegal bootlegger using illegal equipment and should be in jail on a criminal conviction, not being published in an amateur magazine.

Then we have the article that, merely because a ham was a Conditional or Tech, says it was justifiable and cute for an Advanced-type ECM engineer to break the law in dozens of ways to "teach him a lesson." All because the so-called offender was a Conditional whose comments the hot-shot engineer didn't like. I'd rather see ads by Trigger.

In the past, your mag always had the best of amateur radio, every article seemed to be informative, and construction articles for amateurs were of the accepted *ham* type, i.e., licensed and law-abiding. Other than the abovementioned drivel, though, you still have the best mag published and someday you will get back to the average amateur and make us feel we are with you on a one-to-one basis as we read your editorials.

Tallula IL

EGYPTIANS

Now the "other side" has had its say in the pages of *73*, with the word of Bess Nelson (September, 1979, page 156) pitted against the earlier letter of Tania Miller (August, 1978, page 8) in regard to the situation prevalent at the Egyptian Radio Club, Granite City IL. It is one of the oldest, strongest, and most prestigious clubs in the nation, whose chief accomplishment seems to have come 40 years ago, within a decade of its founding, when it won ARRL's Field Day three years in a row.

When I saw Tania's letter, I thought it a bit hasty in remonstrance against an admitted problem, but now I think she, not Bess, had the better perspective on things there.

At present, Mrs. Nelson is editor of the club's newsletter, a journal I had the honor to publish several years ago. Her latest edition, besides containing two unsigned letters—something most of the rest of us editors stopped airing quite a while back—gives the news that the club's regular membership stands at 126, with the obvious implication that the membership is *up* to this figure. The true picture is that club membership must be *down* to 126, following the mass exodus of 29 former members, according to my sources, who walked out the door, led by old-timer Harry Turner (holder of world record for sending code on a straight key—35 wpm—see *73 Magazine*, Jan., 1976, page 5), who turned his back in disgust and dropped not only his membership, but also his position as club treasurer, a post he had held for more than a quarter century.

Up until early this summer, I had felt sure that "our" problems would soon be resolved and we would all be back in the same boat again. But I now no longer think this is possible. The arrogant and supercilious behavior of a small knot of hierarchical dictators within the club has made any broadly-based "aura of good feeling" an impossibility. Oh, not that disagreements are ever expected to end, but they need not break up the party. To be sure, old traditions and ideas must and will be changed, and I never particularly agreed with the notion that women should not be members of the club. But it was not this issue that was at the heart of the troubles—rather like the issue of slavery, destined to be the most memorable point of the American Civil War, but which was not really the cause of it all. The more likely situs of the ERC problem is exactly what Bess points to: feelings of power on the part of a chiefly self-appointed elite within the club.

Oddly enough, my strongest disagreements have been with Harry Turner himself, who once walked out of a board of directors meeting because I was there although not a member, but at the invitation of that body. But Mr. Turner and I can stick to our positions responsibly and still keep our composure and our friendship—as we have continued to do. With the 27 others, I must agree, there's little point in continuing the animosity; I just walked away from it, too. But I don't like to see in print an appearance that the "good guys" won, when they didn't.

ATV

On the night of September 4, 1979, all hell broke loose on ATV. At eight thirty pm, VE3IWP, who lives in Toronto, informed me via two meters that W9ZIH from Chicago was coming in on his screen. I fired up my TV station, and sure enough, there he was. I just couldn't believe that I was receiving an ATV picture all the way from Chicago (Hickory Hills) IL about four hundred twenty miles away, while my normal range is about seventy to eighty miles. He was working VE3EYR in Brantford, Ontario.

After that contact, he worked W3POS in Erie PA, approximately four hundred miles between the two stations. At ten pm, I got ahold of W9ZIH myself; we worked both ways, live on camera as well as sound. He received me P4, and I received him P5 (broadcast quality). I nervously took some pictures and made a video recording for future reference. W9ZIH was on for several hours, not just a few minutes as might be expected. VE3EYR, VE3IWP, and myself were in contact with each other on two meters. There were times when I would almost lose W9ZIH, and VE3IWP, who is fifty miles from me, would see him P5, and sometimes conditions would be reversed.

After I finished my ATV QSO with W9ZIH, I picked up N9AB from Mundelein IL, which is four hundred forty-one miles from me. We only flashed our logos at each other for a while; he came in P2 at times. We also saw K9KLM from Oak Creek WI once; he was P3 on my screen and is four hundred eight miles away. Later on that night, W2RPO in Lockport NY and VE3AHS in Weliand, Ontario, also saw W9ZIH. Needless to say, I had a sleepless night after all this. I don't know who holds the world record for DX on fast scan, but we might be close to it. Ron W9ZIH was running five hundred Watts out on 439.25 MHz video, and one hundred fifty Watts on 443.75 MHz sound; his antenna on video had one hundred seven elements up sixty-five feet. I was putting out forty Watts on video and ten Watts on sound with a forty-eight element antenna on video and twenty elements on sound. My converter and preamps are home brew as well as my transmitting equipment. I am not trying to take any credit; we were all active in this and were very enthusiastic. We all hope that what has happened to us might spark some interest in others. I have been a ham since 1959, but after the initial excitement of the first several years wore off, I lost interest in the hobby. After getting involved in amateur fast scan TV, I got my old spirit back again. There is no better way that I can think of for old-timers who are getting stale to rejuvenate the interest in our wonderful hobby. ATV has got all the excitement of the early days of radio, with lots of room for experimentation.

EUREKA!

Re: 890-960 MHz Machine-to-Machine CB

Eureka!

It now looks fairly definite that the new proposed amateur band in the 890-960 MHz band will not remain vacant due to the lack of equipment.

Our Canadian Department of Communications, through its Director General of Regulations, is proposing a 5-MHz portion be set aside for CB operation. They are proposing a wide-open mode of operation including man-to-machine and machine-to-machine. Comments on band plan, modulation schemes for voice and data, and, most important, eligibility requirements are being requested from the public.

My opinion is that the DOC feels that the big boys, G.E., Motorola, etc., are not being aggressive enough in their development in this area for the private commercial user. The commercial manufacturers keep screaming for more spectrum rather than developing improved technology to communicate within the spectrum they now have.

Motorola has developed a DVP Digital Voice Privacy System along with Harris and pos-

sibly others. This appears to have been developed only for the purpose of privacy. I feel the big "M" and others are going to be left out in the cold unless they and other *domestic* manufacturers join in on the development of this proposed new band, if it is approved.

Of course I am excited because this brings new and inexpensive technology to the amateur portion of the band.

Paul Cassel VE3AVY
Kitchener, Ontario

Well, unless we somehow manage to get a lot more licensed amateurs than we have now, I'm not sure that we will have enough people to do much pioneering on a new band. Of course, the availability of relatively inexpensive equipment would help a lot and might take some of the pressures off 450 MHz as a repeater control band. But remember that we have a 1215-1300 MHz band which is virtually unused... primarily because it is so difficult to make the necessary equipment.

The 900-MHz band might be one where amateur TV fanatics could set up a series of repeaters and make it possible for that mode to cover more ground. — Wayne.

THINK TANK

I'm not writing to bitch or complain about anything. As a matter of fact, I'm writing to obtain my copy of "How to Write for *73*." Hopefully, we can strike up a mutual agreement whereby I give you excellent articles for publication and you give me money!

I also want to comment on *73 Magazine* in general. I've been a reader of *73* since I was first licensed in 1963. I've followed your magazine's growth from "just another ham rag" to the best ham magazine currently being published. *73* gets in my mailbox first (most of the time) and gets read the longest. The articles are, by far, the most practical and fairly easy to duplicate. The articles also provide an excellent base for "think-tanking" my own projects.

I was delighted with the letter from K8DNV about "Wayne Green's Lair" in the July, '79, issue. Doug DeMaw W1FB has long been one of my favorite authors. Unfortunately, the rest of the senior ARRL staff don't share his opinion.

Several hams here in England are in the process of forming a G5 Amateur Radio Club for all licensed G5 operators. The unofficial G5 calling frequency is S19 (no relation to the CB counterpart) or 145.475 (simplex) MHz. No HF net has been set up as yet. *So far, we have* about 10 interested hams. Once we get a few more together, we'll have election of officers, formation of a G5 awards program, and all the other things that go into the makings of a ham club. So, any G5 licensed ham who would like to get in on the ground floor of the G5 ARC, please contact G5CSU at 10 Apple Close, Lord's Walk Estate, RAF Lakenheath Camp, Brandon, Suffolk, IP 279 PJ (my British mailing address), or come up on S19 to get full details.

One more item: 29.6 MHz FM is alive and well. G5BRB has a rig on 29.6 FM and I'll have an old Motorola L41 on as soon as the crystals come in, so look for some G5 activity on 10 FM from Jolly Old England.

That's about it for now. Once the G5 ARC is formed and the awards program is adopted, I'll provide you with the details. Keep up the good work in *73* and *Kilobaud MICROCOMPUTING*.

Richard H. Arland G5CSU
APO New York NY

THANKS, HARRY

I would like to comment on the article, "The 80 Meter Coax L," by Harry Pardue in your August, '79, issue.

Even though Fig. 1 is in error to the extent that the feedline braid is not connected to the ground rod as it should be (and as it is described in the text), the article is a fine contribution to our hobby and I wish to thank Harry and *73* for its publication.

My version of it, which *runs* 20 feet on the vertical to a chimney bracket and then slopes down about 5° to anchor to a nearby tree, shows an swr of about 1.2 and required no trimming whatsoever! First contact was Oklahoma City to St. Louis, which approaches 600 miles; at 3:00 pm, that's not bad (80m Novice CW).

Clarence H. Dollmeyer KA5EKM

VINTAGE QSLS

I purchased the following QSLs at a local stamp and coin dealer. He had purchased them at an estate sale and was selling them to stamp and postcard collectors. If any of the following hams are still active and would like to have the QSL, send me your name and QTH and I'll send you the card.

W1BYF—'33; W1BFP—'31; NU1VT—'28; NU1WV—'28; W2AMM—'29; 2AON—'27; 2BBC—'26; U3BNU—'25; 3LB—'28; U3QW—'25; U3VF—'26; 4AG—'23; 4EE—'25; 5PE—'22; 5WK—'25; 6ACH—'26; W6AIF—'32; W6AIY—'31; 6ARW—'25; 6ASL—'28; 6AZZ—'26; 6BDW—'28; W6BMH—'31; 6CZU—'26; 6DAQ—'25; 6DOG—'28; 6DTP—'28; W6EBV—'29; W6FOC—'34; W6QY—'29; 6RJ—'25; 8AIB—'21; 8AVZ—Sept., '26, "Been on air week hr"; 8CTD—'24; W8ESG—'55, "ex-W8AKV"; 9AIG—'21; 9ASK—'22; 9ASN—'21; 9BEW—'24; 9BHB—'24; 9BOB—'24, "ex-9BDQ"; 9BQZ—'25; 9BVK—'24; 9DAE—'27; 9DHJ—'24; 9DMX—'24; W9FTR—'31; 9HO—'22; W9LAY—'33; U9WK—'27.

Is there a radio museum which would be interested in a donation of unclaimed cards from the above?

SHINGLE POWER

Without a doubt, WB6AAM (September Letters) is right in urging hams to get busy and power their rigs with solar and alternative forms of energy. Considering the momentum that Jane Fonda and the "hate nukes" society is gaining, blackouts are coming. If you like the gasoline shortages of the '70s, you will love the electric power shortages of the '80s and '90s. (For more information, write to Department E, National Rural Electric Association, 1800 Massachusetts Avenue N.W., Washington DC 20036.)

If anyone can come up with a solar cell that can be used instead of shingles for a roof, it will be welcomed across the nation (even by power companies). Power companies need some support.

TMI was the worst nuclear disaster in history—yet no one was hurt. Oh, yes, it is claimed that there may be one to ten more cases of cancer in the next decade, but peddlers of hysteria fail to mention that over 325,000 cases are expected anyway. Yes, TMI was a tragedy. It set back nuclear power 20 years. Yes, there are risks involved with nuclear power, but these are small compared to others that we take.

For more eloquent thoughts on the subject, readers are referred to A. Hailey's new book, *Overload*. It provides sober food for thought.

MALICIOUS FOOLS

This will no doubt be one of many letters to you highly commending the fantastic job done by the hurricane watch during the recent hurricanes, David and Frederic.

I cannot commend too highly the excellent work done by all those running the net and most particularly by Ellie K4RHL and Lynne WA1KKP. So many people who benefited from information received by their tireless efforts will hold them in warm regard, and for those of us who sat on the sidelines during the long hours, their patience and fortitude under difficult conditions was more than admirable.

The difficult conditions were unfortunately made doubly so by some sick pranksters or malicious fools who persisted in heckling and attempting to block vital transmissions with all manner of QRM. It is hoped that the FCC is in a position to take positive action. I think that every ham who heard the QRM deplored it and would love to have been in a position to throttle the bastards.

George Benson GY5GB
Kingston, Jamaica

Ham Help

The Cincinnati Area UFO Net has been active Thursday evenings on 28.8 MHz (alternate frequency 28.795 MHz) at 0100 UTC. A Saturday afternoon section will be inaugurated beginning January 5, 1980, at 2000 UTC. Stations in the western, southwestern, and southern states with UFO traffic or interest are cordially invited to check in on or about 28.8 MHz at that time. Net control will be KA8BVO, with K8NQN providing assistance and liaison with the Mutual UFO Network nets which meet in the morning on 40 and 75 meters.

Information relating to UFO movies shown to radar specialists in the military service during the 1950s is of particular importance. If you or someone you know has seen such movies, please contact Mick Georgin KA8BVO, 8788 Mockingbird Lane, Cincinnati OH 45231, in confidence. His landline is (513)-729-3430. Thank you.

David L. Dobbs K8NQN
6612 Pleasant Street
Cincinnati OH 45227

If anyone has any information on any organized net of Masons *on the amateur* bands, please drop a line to Bill Williams, Box 419, Philmont NY 12565. Thank you.

Awards

from page 22.

of the amateur receiving this award.

WORKED ALL SM
WASM I

This award is offered by the Swedish Amateur Radio Society as tangible evidence of the proficiency of foreign amateurs in making contacts with the various call areas of Sweden.

The award may be claimed by any amateur in the world who has fulfilled the following qualifications. Swedish amateurs will not be eligible.

European amateurs must work two stations in each of the eight Swedish call areas. These areas are SM1 to SM7 inclusive and SMØ. The contacts may be made with SM, SK, and SL stations, and all stations have to be land-based. All contacts must be made after World War II. Non-Europeans need only contact one Swedish station in each of the required call areas.

The contacts may be made using any authorized amateur band and any type of emission. No endorsements for work on any certain band or for phone work will be given.

The applicant must submit a list of claimed contacts which may be verified by two amateurs, a local radio club secretary, or a notary public.

To cover expenses for this award, which is cloth and beautifully designed, there is a fee of 11 IRCs. Applicants are to send this fee and list of contacts to: SSA Diploma Manager, Ostmarksgatan 43, S-123 42 Farsta, Sweden.

Join us again next month as we span the globe looking for additional incentives to make those new contacts worthwhile. Continue to forward award information as it becomes available. Perhaps your own radio club sponsors an awards program. Why not share it with our readers worldwide?

Contests

from page 35

GARDEN CITY CONTEST
Starts: 1200 GMT December 8
Ends: 1159 GMT December 9

The Visvesvaraya Industrial and Technological Museum, Bangalore, and the Bangalore Amateur Radio Club cordially invite all amateurs to participate in the VU2DX Contest. There will be two groups of operation, with one group operating both 20 and 40 meters and the other group operating only 40 meters. Log sheets regardless of score will be of definite interest to all concerned along with any photographs of the shack and contestants. The contest is open to all amateurs but restricted to CW only and single operators. The station must be manned by the individual amateur contesting without receiving any assistance from any other persons for log-keeping or spotting, etc., during the entire period of the contest. Stations may be worked once per band and valid points can be scored by contacting stations not in the contest provided complete RST exchanges are made and logged.

EXCHANGE:

RST and serial QSO number in three digits or more.

SCORING:

Each completed QSO counts 1 point with the following multipliers: VU station contacting Asia = multiplier of 1, contacting Europe, Africa, and Australia = multiplier of 2, and contacting North and South America = multiplier of 3.

ENTRIES AND AWARDS:

All entries to the contest must be postmarked no later than December 31st and sent to: The Convenor, Garden City Contest 1979, Visvesvaraya Industrial and Technological Museum, Kasurba Road, Bangalore 560 001, India. There is no entry fee and the entries must be a true copy of the actual log for the contest period. All DX stations who contact 20 or more VU2 stations will be issued a "Garden City Certificate."

TEENAGE RADIO SPRINT
Starts: 0000 GMT December 22
Ends: 2400 GMT December 23

Sponsored by the Twin City Teenage DX Club, the contest's purpose is to promote teenage amateur operators and to help friendship with other teenagers. All hams over 21 years of age must work only stations under 21 years of age. Stations under 21 may work all stations. To show under 21, put "/T" after your callsign. General call will be "CQ TNGE TEST."

EXCHANGE:

RS(T) and age; if over 21 and you don't want to send your age, simply send xx in place of the age.

SCORING:

Score 2 points per QSO in one's own country, 4 points for all DX QSOs. Double QSO points (4 and 8 points) for QSOs on 160, 80, or 40 meters. Multiplier is number of different prefixes worked on each band and mode. No crossband contacts except via OSCAR.

FREQUENCIES:

CW—40 to 60 kHz up from bottom of band, 10 kHz up for Novice.

SSB—near or around 3975, 7275, 14275, 21375, 28575.

6 and 2 meters may also be used.

ENTRIES AND AWARDS:

Awards will be given depending on the activity! Entry classes include single-operator, all band; multi-operator, single transmitter; and multi-multi. Also, special classes for CW only, SSB only, or mixed. A summary sheet is requested and a sheet with scoring and contact totals along with the usual contest information signed by the operator is requested. All logs must be sent to Greg Deuhs KBØCV, 1945 Ashland Avenue, St. Paul MN 55104.

12TH AUSTRALIAN JAMBOREE
December 29, 1979—
January 7, 1980

The vast distances and small potential of people power do not deter Western Australians from thinking big. Although covering one third of the Australian continent, making it the biggest state in the world, the West has only 8% of its population at about 1.2 million people.

1979 is the state sesquicentenary (150th anniversary) year, so many years ago the W. A. Scout Branch applied for the regular three yearly Australian Jamborees always previously held in the populous eastern seaboard states. This was agreed and the Jamboree becomes the final event in a year-long birthday party embracing the whole population from all towns, utilizing all activities which could be imagined.

World Scout Bureau gave it regional status as the 4th Asia-Pacific Jamboree. Subsequently, with the postponement of the 1979 World Jamboree in Teheran, Iran, it became one of the 1979 World Jamboree Year Camps. About 8000 scouts from eastern states and over 1000 from 30 overseas countries will mix with 2000 locals for eight days of camping, activities, sight-seeing, shopping, trying new skills, fraternization, and fun.

Because amateur radio amplifies many of these Jamboree concepts, e.g., new skills, fraternization, and fun, local amateurs are preparing one of the biggest VK6 stations ever mounted. Facilities will include:

- a high-frequency station on 20 or 15 meters operating round the clock beaming the world, including eastern states;
- a high-frequency station on 15 or 10 meters operating all day beaming eastern capitals;
- a high-frequency station on 40 or 80 meters operating as required with dipole aerials favoring north/south;

Results

RESULTS OF 1978 TOPS CONTEST

Winner was HA5NP—Robert Soket of Budapest, Hungary
No. of contacts—549 Number of points—1014
No. of prefixes—115 Total score—116,610
FT-250 at 200 Watts

Second was HA9RU—Janos Pokker of Miskde, Hungary
No. of contacts—480 Number of points—851
No. of prefixes—130 Total score—110,630
FT-250 at 200 Watts

Third was YU1OCV—Vojislav Kapun of Kikinda, Yugoslavia
No. of contacts—386 Number of points—810
No. of prefixes—118 Total score—95,580
FT-200 and amplifier at 500 Watts

•a RTTY station operating most of the time as signals are available;
•amateur TV F/S on UHF with special receivers located in subcamp fraternity areas;
•three or more VHF stations on 2 meters and 6 meters and perhaps other bands; and
•a workshop where, under the supervision of amateurs, the scouts will be able to build a simple electronic working project.

In addition, a broadcast band radio station on 1610 kHz is in preparation so that items of news, happenings, instruction, and music can be conveyed quickly to all scouts for their entertainment.

It is expected that the stations will be busy with amateurs in contact and that the special Jamboree Badge QSL Card will be in demand. It is hoped also that scout groups and units with radio amateur capabilities or friends will make a special time to get together during the Jamboree to make contact. Further, it is expected that many groups around the world will want to make contact to find out how the Jamboree and their particular people are progressing. To assist these contacts, skeds will be accepted for a particular frequency, date, and time. Mail to: Scout Amateur Radio VK6SH, 12th Australian Jamboree, Box 467 P.O., West Perth, Western Australia 6005.

To test propagation conditions as far as it is possible, all skeds will be acknowledged by trying all contacts with one of the VK6 amateurs on the organizing team exactly four weeks to the day and hour on which the contact is asked for. If that sked does not work, another will be tried a week later—three weeks from the Jamboree. The sooner that skeds are requested, the better can the arrangements be.

The Jamboree is being held at Perry Lakes Stadium and associated grasslands—an international track and field site established for the Empire Games in Perth in 1962. The radio station is to be sited on the top floor of the stadium building using most of an area 250 feet long by 11 feet wide.

For further information, contact: (Jamboree) Mr. Alex Shaw, The Scout Association of Australia (W. A. Branch), Box 467 P.O., West Perth, W. A. 6005, phone 321-7217 (Mr. Doug Napier); or (Radio) Mr. Peter Hughes, Asst. Branch Commissioner, 58 Preston Street, Como, W. A. 6152, phone 367-1740 (mornings 364-7588).

CANADIAN CHRISTMAS QSO PARTY

Starts: 0001 GMT Saturday, December 30
Ends: 2359 GMT Saturday, December 30

This contest is sponsored by the Canadian Amateur Radio Federation and is open to all amateurs. Everybody may work everybody on all bands, 160-2 meters, CW and phone combined. Entry classes are single-operator allband and single-operator single band.

EXCHANGE:

Exchange signal reports and consecutive serial numbers, e.g., 599001. VE1 stations also send province.

SCORING:

Stations may be worked twice on each band, once on CW and once on phone. Score 10 points for each contact with Canada, 1 point for contacts with others. Multipliers are the number of Canadian provinces and territories worked on each band and mode (12 provinces/territories times 8 bands times 2 modes for a maximum of 192).

FREQUENCIES:

CW—1810, 3525, 7025, 14025, 21025, 50100, 144100 kHz.

Phone—1810, 3770, 3900, 7090, 7230, 14150, 14300, 21200, 21400, 28400, 28600, 50100, 146520 kHz. Suggest phone on the even hours GMT, CW on the odd hours.

ENTRIES:

Entries, with dupe sheets and summary sheet, must be mailed by January 31, 1980, to CARF, Box 76752, Vancouver BC, Canada V5R 5S7.

OOPS

Hope we didn't cause any problems, but there was a slight typo error in the September contest calendar write-up on the 89'ers Run. Certificate applications should go to WB5YKD and not WB5TKD as listed.

W2NSD/1
NEVER SAY DIE
editorial by Wayne Green

from page 6

emissaries a few minutes before a net is scheduled to open. They can get on, check around, and, if the net frequency is in use, find a spot for the users to move, if they can be coaxed into it. Most hams are like me, they will do almost anything for you if you ask nicely . . . and will fight to the death if told what to do.

If the chaps are obstinate . . . or if one of the net people trying to get a clear channel is less than diplomatic, there should be an understanding that the net can move up or down a few kilohertz to keep peace in the family. Blessed are the peacemakers for they are the first to get killed when war starts.

FINDING THE JAMMERS

Little has been written or even done about trying to find the jammers. We are a whole generation behind in working on the problem. The FCC and other agencies have gone years beyond us in the design of sophisticated equipment for searching out jammers . . . while we are still out waving loop antennas around, chasing off in the opposite direction at top speed.

I've heard that the FCC is able to get a fix on a jammer within one or two seconds . . . or is it milliseconds? As I've mentioned before, I'd sure like to have some articles in *73* on how to build some modern DF equipment. The Happy Flyers in California have run up an impressive record of tracking down repeater kerchunkers and jammers by plane, but I should think that we might be able to go beyond that before long.

We could use articles on techniques for identifying stations by looking at their keying patterns. This means freezing the leading edge of a kerchunk and looking at it on a scope. I understand that every rig may have its own identifiable pattern. We want to know more about triangulation via receiving both the signal on the repeater input frequency and the repeater output. If pairs, or more, of operators could get a net going to do instant triangulation, that might be worthwhile. Let's start tackling this.

AFTER YOU FIND 'EM

In most cases, a ham will shut up once he knows he's been discovered. In those cases where the ham is blatant about it, stronger measures are needed. I've heard that massive visits from concerned local amateurs can have a settling effect on strong-willed jammers. It is impressive when a hundred hams drive up and come to your door to reason with you . . . particularly if they have sticks in their hands.

There are a lot more articles needed on ways which have worked to calm down hard-core jammer cases. I doubt if broken arms are necessary—just some powerful reasoning.

THE WORST WAY

Amateur radio has a reputation of being self-regulating. We try, as much as the FCC will permit, to generate our own rules and we have an enviable record of sticking to them. I can't think of a case yet where FCC-generated rules have been nearly as well suited to our work as our own rules. Amateurs are very considerate of each other, most of the time, and tend to go overboard in the protection of special interests more than in putting them down.

So, in view of this image of self-regulation, every time we turn crying to the FCC over some interference problem, we are hurting our image with the outfit where our image is the most important. We should move heaven and Earth to handle our own problems and not keep calling up the FCC every time some idiot lets loose.

WHAT'S NEXT?

Until we get a lot more information on direction-finding and have a few dozen stations set up for instant fixes, there isn't much we can do. Swinging a three-element 20m beam is hardly the way to try to locate some idiot in Nebraska who is raising hell with hurricane communications. We need to be able to pinpoint the trouble quickly and have things organized enough so we can get in touch with a net in the specific area which can get action.

Clubs which get set up to participate in direction-finding can let me know and I'll try to run a list so other groups will know whom to contact when a problem arises. I should get contact call letters and phone numbers, together with some idea of the bands which can be DFed, etc.

Let's get going on this . . . with articles and organization.

COOL THE HAMFESTS

The *QST* editorial suggesting that hamfests be cut back sure wasn't given much thought before being put to paper. Sure, there are major problems for some of the ARRL conventions . . . there have been real bummers. But this doesn't mean there is anything wrong with hamfests. The Milwaukee Central Division Convention, after two solid years of planning and work, featuring Harry Dannals as speaker, brought in eight exhibitors and a crushing

400 in attendance. The National, in Baton Rouge, also featuring Harry, was another disaster.

Let's compare that with the first-time hamfest in St. Louis (boycotted by the ARRL) which drew about 2,500. There were over 1,500 put to sleep by my talk alone. This year, the St. Louis crowd is loaded for bear . . . they've rented the largest riverboat on the Mississippi for the banquet . . . seven decks and a capacity of 3,500 . . . two orchestras . . . and some entertainment by Wayne Green. I understand that there is a possibility that Arthur Godfrey may be able to make it . . . he's been sick lately, so we don't know yet. And there will be a lot more entertainment.

You may be sure that every exhibitor from last year will be back . . . they cleaned up from the money-waving crowds. I predict there will be many more ham and computer dealers and manufacturers exhibiting this time.

The fellows down in Maryland are cooking up a big event for the spring . . . again featuring me. Why do I draw crowds? Well, I say exactly what I think about things . . . and I'm able to say a lot at talks like this that I would never be able to print. Perhaps I go too far sometimes and say things, which, though true, shouldn't be let out of the bag.

A lot of people come to see what Wayne Green is really like . . . since I aggravate the hell out of them in my editorials . . . and they usually find that after 40 years around this hobby and 27 years of publishing, I really do know what I'm talking about.

No, there's nothing wrong with hamfests except the stifling effect of the League trying to keep the truth from getting out. Boy, do those fellows remind me of the Kremlin!

WHAT'S DOING AT 73?

With the ham field in the doldrums, we're not indulging in many expansion plans for *73*. It is doing well, obviously, but the growth is mainly in the microcomputing end of things. *Kilobaud MICROCOMPUTING* has been growing steadily. We have a new magazine, *80-MICROCOMPUTING*, for the TRS-80 owners, starting in January (out before then). The *Industry Newsletter* has grown into a magazine of its own . . . now pushing 60 pages a month, and with no end in sight. The Instant Software publishing is now perking along, with over 100 program packages already in publication and a couple thousand in various stages of production. Since this division has only been in serious production since the first of the year . . . and since it takes about six months to process and publish a program, the project is doing surprisingly well.

Instant Software is now being distributed all through Europe, in several hundred outlets in the US, in South Africa . . . and will soon be distributed in Asia. It's going in Australia and is getting started in South and Central America. Programs are being produced in German, Italian, French, Spanish, and even English.

A headquarters building and the seed staff for still another magazine has been organized in Boston. This will be a magazine devoted to leisure in that area. If it works well, it might expand to similar magazines for other cities, just as the New York, Philadelphia, and Boston magazines have proliferated. This is scheduled to kick off early next spring.

Having had dozens of hobbies and interests, the leisure magazine idea seemed a natural to me. I've been heavily into horseback riding and horse training, flying, skin diving, skiing, gourmet cooking, sports car rallies and gymkhanas, boating, water skiing, mountain climbing, hamming, hobby computers, car racing, spelunking, restauranting, and more things which don't come to mind immediately, so what better than to do a magazine about all of the activities which are possible in and around greater Boston? It will be fun.

DECEPTIVE ADVERTISING?

Every time I see an ad for the Little Giant antenna in *Ham Radio Magazine*, I laugh. From my viewpoint, this piece of garbage is a pure rip-off and I feel that no reputable publisher should accept an ad for it.

In addition to knowing enough antenna theory to recognize that the contraption is useless, I've also tested the silly thing. It first popped up around 1958 when I published an ad for it. I got in touch with the "inventor," a very nice chap, Stan Byquist . . . K0AST, I think was his call. I looked over his literature and tried to figure out some way . . . any way . . . that it could be more effective than a piece of window screen. I failed, so I got Stan to send me one.

Sure, I could tune it up . . . heck, you can make almost anything load . . . but it was no more effective than an old window screen. Stan said he was getting good results . . . but when he said he had to keep the feedline away from his tower to get good reports, I knew what was happening . . . it was the feedline which was radiating and the intricate (and expensive) lump on top was a weird loading coil, in effect.

I talked it over with Sam Harris W1FZJ and he agreed. But, just to make sure, he borrowed the kludge and tried it every way possible . . . he felt that it was *inferior* to a window screen. I passed the bad news along to Stan and told him we would accept no more advertising. A short while later, I noticed an order from Stan for an 8JK antenna handbook coming in to Radio Bookshop. I hope Stan read the book . . . but I somehow doubt it.

By 1960, Stan had moved to Ohio as K8VRM and had put aside his Little Giant antenna (oh, I forgot to mention . . . that was my idea for the name of the dumb thing). He took on *73 Magazine* as a rep for the Ohio area and did a bang-up job of getting sales with electronics stores. Stan is a very nice guy and did a great job as a rep.

In the 60s, he got involved with hardware for CBers . . . switches, power meters, etc. Then, for some reason, the Little Giant got going again and I see ads for it in *Ham Radio* every now and then. I've talked with 'em at *HR*, so they know the antenna doesn't work. Perhaps they feel that the ad, which says that the antenna "may not outperform a full-sized beam," is warning enough to the wise. That is a true statement. I would not expect the antenna to outperform a full-sized beam, even if it were lying broken on the ground.

Shouldn't there be some responsibility on the part of publishers to protect the unwise from being sucked in on bummers? I have a whole list of firms which I won't permit to advertise in *73* . . . though most of them have gone back into the woodwork. I haven't seen a Dycomm ad in a while. And we shut down ads for EBC, Ebka, Processor Tech, Swivitek, Valpey Fisher, SAROC, etc.

The ARRL makes a stab at trying to protect the *QST* readers, but they permit rip-off advertisers that I would never let run. I do enjoy their bragging about what few they do avoid.

Let me repeat something I keep repeating: If you feel ripped off over any ham gear, please let me know the details. I prefer you write a letter to the perpetrator with all details and send a copy to me.

1980 ASPEN CONFERENCE

Ham manufacturers are always looking for some new concept which might permit them to bring out ham equipment which would make all past rigs obsolete, thereby triggering a massive buying of new equipment. Since we're talking about something on the order of $1 billion or more in sales, this is not to be treated lightly.

Oddly enough, hams, too, are looking for exactly the same thing . . . something new. It is fun to buy a new rig, but the expense is a major one and not to be made unless there is a darned good reason.

I think I have two breakthrough ideas which together could make all existing rigs completely obsolete . . . and that includes both low-band gear and FM equipment! It will be possible to use these new modes of operating with add-on units for starters, but I suspect that most amateurs will want to opt for equipment with these new modes built right in. These concepts will, I think, make it possible for us to see profound changes in amateur radio over the next few years.

The first public unveiling of these ideas will be at the Aspen Ham Industry Conference, January 12-19th. The admission fee will be a signed non-disclosure contract for one percent of the wholesale price of any equipment sold using the concepts I shall divulge.

It is too late now for us to make reservations for you, so if you are going to attend the conference (which includes a lot of skiing), you'll have to handle the reservations yourself. Please do let Sherry know if you are going to be there so we can include you in the activities and workshop session (Sherry Smythe, *73 Magazine*, Peterborough NH 03458). The main group will be staying at the Limelight, in downtown Aspen.

AUGUST WINNER

Amassing the largest total vote ever recorded in our Most Popular Article contest, "You Can Watch Those Secret TV Channels" walked away with August's award. Authors Jim Barber K0JB and Jevon Lieberg K0FQA will be splitting the $100 prize. If you have a favorite article in this issue, be sure to use the Reader Service card ballot to let us know what it is.

Ham Help

I need a schematic, manual, or data sheet on an Instrument Corporation of Florida very low frequency receiver, model R-500. This fixed-tuned 5-channel receiver was part of a Cubic Timing Systems network.
